In making the set for planting gooseberry-cuttings is in autumn, just before their leaves begin to fall. The cuttings should be taken from bearing shoots, rather than those gourmands which issue from the main stem. Cut them to such a length as the strength and ripeness of the wood will bear, and cut off all the buds excepting three, or at most four at top, and train the plants will be cut from the blooms, and a shortened shoot, 6 inches, and the branches trained towards at an angle of 45, or better if 45, Haynes advises taking off cuttings in July, when the fruit is on the tree, in order to make sure of the sorts. He says, by immediate planting, watering, and shading, as good plants are produced as from ripe wood-cuttings. (Tr. on the Gooseberry, & c. p. 92.)

461. Soil and site. Any good garden-soil, on a dry bottom and well manured, will suit the gooseberry. That which is soft and moist produces the largest fruit. The situation should not be under the drip of trees over much shaded or confined, otherwise the fruit will be small, ill flavored, and the plants apt to mildew. Forsyth says, gooseberries should be dug every year, or at least have a good coat of dung once in two years. Haynes recommends a mixture of peat and loam well manured, and a shaded situation. The last he proposes to effect by planting among his compartments of gooseberry, rows of Jerusalem artichokes in the direction of east and west.

461. Final planting. “The season for planting gooseberries is any time during open weather from October till March. When trees are procured from the public nurseries choose such as are of some advantage, and are full hardened, planted in boxes. Goosberries are generally bought from the nurseryman in the general supply be in standard bushes, and planted principally in the kitchen-garden, in single rows, along the boundary edges of the main compartments, or outward borders, from six to eight feet apart; or some may be planted in rows, to subdivide extensive compartments. When the object is to raise large quantities of fruit for market, the picked or better trained, will be set six or seven feet apart, and proceed the closeness of the tree. That it will be possible to plant a few choice sorts against south and other sunny walls or paling, for earlier and larger fruit; and on north walls, to ripen late in succession.” (Abercrombie.)

462. Pruning. “In making rows about London, which I have done, which are from eight to ten feet apart from row to row, and six feet apart from plant to plant in the rows. In small gardens, I would recommend placing them in a compartment by themselves, at the distance of six feet between the rows, and four feet from plant to plant; or you may plant them round the edges of the compartments, about three feet from the path; you will then have a ground for cropping, and a man, by setting one foot on the border, can gather the gooseberries without injuring the crop.”

464. Neil says, “In some places gooseberry-trees, on the sides of the borders, are trained to a tall stem, which is tied to a stake; this, though six or eight feet high, occasions scarcely any shade on the border, and it does not occupy much room, nor exclude air; while, at the same time, the stem becomes close hung with berries, and makes a pleasant appearance in that state.” (Ed. Enc. art. Hort. § 161.) Maier observes (Hort. Trans. vol. 3. p. 468.), that as the crop of ripe fruit is often increased by leaving the largest and earliest berries prematurely gathered, whilst green, for tarts, a sufficient number of trees of such varieties as are the earliest, should be planted in a separate compartment of the garden, and devoted exclusively to the use of the kitchen, for tarts and sauce.”

466. Mode of bearing. “The gooseberry produces its fruit not only on the shoots of last summer, and on shoots two or three years old, but also on spurs or spurs arising from the elder branches along the rows; but the former afford the largest fruit. The shoots retained for bearers should therefore be left at full length, or nearly so.” (Aber.)

467. Pruning. “The bushes will require a regulating pruning twice in the year.”

468. Summer pruning. “Where any bushes are crowded with cross and water shoots, of the same year, shading the fruit from the sun, and preventing the access of air, thin the heart of the plant and other part of the tree, by cutting out close, pruning in such manner as to have the summer shoots in general.” Maier says, “it will greatly contribute to the perfection of the fruit, if the very small berries are taken away with a pair of scissors about the middle or end of May; and these small berries, will make your gooseberries thrive as the large tree or as the large fruit; the same for bearing, will be hung with berries.”

469. Winter pruning. “You may proceed to the winter pruning any time from November until the end of February, or until the buds are so swollen that farther delay would endanger their being rubbed off in the operation. Cut out the cross shoots and water-shoots of the preceding summer, and the superfluous branches, and ramblers and shoots, as long as they will be liable to be blown away, when the frost is on the ground, or eye; or if an under-staggerer spring very low, cut it away. Of last year’s shoots retain a sufficiency of the best well placed laterals and terminals, in vacant parts, to form successional bearers, and to supply the places of unfruitful and decayed old wood, which, as you proceed, should be removed. Maier says, “as this is the aim of the first, or second, or third, or fourth pruning, ever at the root, or at the node, or at the terminal branch, or where the branch would thus be too extended, pruning to some competent lateral within bounds.” The superfluous young laterals on the good main branches, instead of being taken off, may be cut into little stabs of one or two eyes; which will send out fruit-buds and spurs. Of the supply reserved for new shoots, the main branches, and the principal branches, are to be cut down to the largest shoots, the multiplied laterals thrust from the eyes of the shortened branches increase to a thicket, so as to retard the growth and prevent the full ripening of the fruit; on which account it is an important part of pruning to keep the middle of the head open and clear, and to let the occasional shortening of the shoots be chiefly made upon the laterals, or branches kept at a distance of at least six inches at the extremities, which will render them fertile bearers of good fruit. Some persons, not pruning the gooseberry-tree on right principles, are apt to leave the shoots excessively close and tufted, while they shorten the whole promiscuously; others sometimes clip them with garden-shears to close round heads; in such cases the buds are injured, and the bush is weakened, or injured in the making wood in summer, from which the fruit is always very small, and does not ripen freely with full flavor.”

460. Forsyth says, “Many of the Lancashire sorts are apt to grow horizontally, and the branches from these are also apt to grow horizontally; which makes them liable to be blown away, especially when they are loaded with fruit. In that case I would recommend two or three hoops to be put round them, to which the branches may be tied, to support them, and prevent their being broken by the wind.”

461. Jeeves has tried training gooseberries on an arched trellis, in the manner of a bower, or arbor, with very good effect. He says, to make the ground safe, the bushes at this distance distance
from each plant, till they meet at top. The advantages of this plan are, beauty of appearance, fruit not splashed by rain, easily gathered, and the ground more readily cultivated. (Hort. Trans. vol. iv. p. 194.)

4553. Prolonging the crop. In addition to planting late sorts in shady situations, the bushes, whether standard or trained, may be matted over when the fruit is ripe, and in this way some of the reds, as the Warrington, and the thick-skinned yellow sorts, as the Mogul, will keep on the trees till Christmas. When a large number of bushes are grown together, and the use of liquid manure, shading, and thinning, the large fruit of the prize cultivator is produced. Not content with watering at root and over the top, the Lancashire connoisseur, when he is growing for exhibition, places a small saucer of water immediately under each gooseberry, only three or four inches from leaves on the bushes. He also pinches off a great part of the young wood, so as to throw all the strength he can into the fruit.

4555. Accelerating maturity. Hunt tried ringing on half a gooseberry-bush, which half produced ripe fruit a week sooner than the other, and twice the usual size. (Hort. Trans. iv. 385.)

4556. Insects, diseases, &c. The caterpillars of saw-flies (Tenthredinidae, Leach) (fig. 495.), of butterflies (Papillæ, L.), and of moths (Phalaenæ, L.) are well known and serious enemies to gooseberries. The larvae of the Tenthredinidae have from sixteen to twenty-eight feet; a round head; and when touched, roll themselves together. They feed on the leaves of the gooseberry, apple, and most fruit-trees, as well as roses, and other shrubs and plants. When full-grown, they make sometimes in the earth, and sometimes between the leaves of the plant on which they feed, a network case, which, when complete, is strong and gummy, and in that change to a pupa incompleta, which for the most part remains during the winter in the earth. The perfect fly emerges early in the ensuing spring; its serrated sting is used by the female in the manner of a wasp, to make incisions in the twigs or stems of plants, where it deposits its eggs. The Caledonian Horticultural Society having “requested information respecting the best method of preventing or destroying the caterpillar on gooseberries,” received various communications on the subject, and the following are extracts from such as they deemed fit for publication:

4557. Gibb describes the large black, the green, and the white caterpillars, with his methods of destroying them. During the winter months, the large black kind may be observed lying in clusters on the under parts, and in the crevices of the bushes; and even at this season (Feb.) I find them in that state. In the course of eight or ten days, however, if the weather be favorable, they will creep up in the day-time, feed on the buds, and return to their nest during the night. Whenever leaves appear upon the bushes they feed upon till they arrive at maturity, which is generally in the month of June; after which they creep down upon the under sides of the branches, where they lodge till the crust of the leaves is dried. In the following spring, the moths become adults, and lay their eggs on the under sides of the leaves, and of the bark. The produce of these eggs, coming into life during the month of September, feed on the leaves so long as they are green, and afterwards gather together in clusters on the under side of the branches, and in crevices of the bark, where they remain all the winter, as already said. Winter is the proper season for attacking them with some sort of poison, though most effectually accomplished by the simple operation of pouring a quantity of boiling hot water upon them from a watering pan, while no injury is thereby done to the bushes.

4558. Take fourteen sorts at a time in the shelly state, lying about an inch under ground. In April they come out small flies, and immediately lay their eggs on the veins and under sides of the leaves. These eggs produce young caterpillars in May, which feed on the leaves till June or July, when they cast a blackish kind of skin, and afterwards crawl down from the bushes into the earth, where a crust of shell grows over them, and in the course of three or four months, to which time the only method of hitherto found effectual in destroying these is, 1st, to dig the ground around the bushes very deep during the winter season, by which means the greater part of them are destroyed, or buried too deep ever to penetrate to the surface; 2dly, in April, when the flies make their appearance, to pick off all the leaves on which any eggs are observable; this is a tedious operation, but may be done by children. If any of the enemy should escape both these operations, they will be discernible as soon as they come to life, by their eating holes through the leaves, and may then easily be destroyed, without the least injury to the bushes or fruit.

4559. Another method is, to burn a layer of rubbish in April, or otherwise to dry up the foliage, though very destructive; they bore the berry, and cause it to drop off; they preserve themselves during the winter season, in the chrysalis state, about an inch under ground, and become flies nearly at the same time with the last mentioned kind; they lay their eggs on the blossoms, and these eggs produce young caterpillars in May, which feed on the berries, and like the other kind, remain under the ground, till full-grown, a mile thick, under the foliage of the bush or tree in the least. A dull day is to be preferred to any other for washing. When the foliage is all off the bushes and trees, wash them over with the hand-engine, to clean them of decayed leaves; for this purpose, any sort of water will do; then stir up the surface of the earth all round the roots of the bushes and trees, and lay a little hot lime about to destroy the caterpillars, with little harm to the bushes or trees. This I have never found to fail of success since my first trial, six years ago. The above-mentioned proportion of leaves, lime, and water,
will serve for two acres of ground or more, covered with trees and bushes in the ordinary manner, and will cost very little money indeed. The same proportion is to be observed in making a wash for the rest of the trees and bushes.

4652. Machay procured some tobacco and soft or black soap, and boiled a quarter of a pound of tobacco with one pound of soft soap in about eighteen Scots pints of water, and kept stiring the liquid while boiling with a whisk, in order that the liquid might be well mixed with the soap; this liquor, when milkwarm, or so cool as not to hurt the foliage, he applied to the bushes with a hand-squirt in the evening, and in the morning found all the ground under the bushes covered over with dead caterpillars. This practice he continued for six years, always when he saw any symptoms of the approach of caterpillars.

4654. Forestry's method is as follows: "Take some sifted quick-lime and lay it under the bushes; but do not at first let any of it touch the branches or leaves; then shake each bush suddenly and smartly, and the caterpillars will fall into the lime; if the bush be not shaken suddenly, the caterpillars, on being a little disturbed, will set forth on the firm as not easily to be shaken off. After this is done, sift some of the lime over the bushes; this will drive down those which may have lodged on the branches. The caterpillars should be swept up next day, and the bushes well washed with clear lime-water mixed with urine; this will destroy any caterpillars that may still remain, and also the aphides, if there are any on the bushes.

4662. In the month of June, one finds the green shoots of the currant plant, and then powders them with quick-lime by hand, so that every leaf both above and below is covered with it. This he found destroyed not only gooseberry caterpillars, but the black fly on the peach-tree. (Hort. Trans. v. 76.)

4675. Harrison considers, that in the currant season, "the eggs of the insects are deposited in crocuses and joints of the tree, also in the ground." In the pruning season, he burns the prunings, and washes the trees with a mixture of quick-lime and water, and then casts in powdered lime among the branches; or, instead of this, he washes the trees with twelve gallons of water, half a pound of tobacco, and six ounces of black soap, and then when the leaves are formed and used when cold. In the following spring, "just before the trees come into bloom," he sprinkles them with lime-water, and throws on them powdered lime, spreading some at the roots of the tree. Soon after the berries are set, he smokes the trees with straw fires. When summer flies visit the trees, he picks off the leaves on which their eggs are deposited.

4689. Pendent treatment. Sprinkling gooseberry and currant bushes with tar-water, prevents the fly or moth from settling on the plant to lay its eggs; this must be done early in the spring, for if done after the fruit is set, it will taste of tar. (J. Busch, in Hort. Trans. v. 58.)

4699. Forcing. The gooseberry may be forced in pots or boxes placed in pits, or in the peach-house or vineyard, for this purpose; the trees in November, removed, and have ripe fruit in the end of April, which he sends to table growing on the plants. (Hort. Trans. v. 415.)

4700. The black currant is a humble shrub, with smooth shoots, strong-smelling trifoliate leaves and hairy racemes, with a solitary one-flowered peduncle at the base of the raceme. The flowers appear in April, of a greenish-white, and the fruit ripens in June and July, and changes from a green to a black color. It is a native of most parts of Europe, especially the more northern parts. It abounds in the woods in the north of Russia; and in the subalpine regions of Siberia, where the branches and berries are very large and sapid. In Britain, it is found in wet hedges, on the banks of rivers, in alder swamps, and sometimes in woods.

4711. Use. The fruit, which has a peculiar flavor, and disliked by some, is seldom brought to the dessert; but it is eaten in puddings and tarts, and made into jellies, and wines. The Russians put the berries into brandy, and the Irish into whiskey, in the same way as the English put cherries; the Russians also ferment the juice with honey, and so form a strong and palatable wine. Many cottagers, who cannot afford to mix green tea with common bohea, substitute one or two dried leaves of black currant, the flavor produced by which few are so acute as to distinguish from that of a mixture of green and black tea. There are no varieties of the black currant.

4713. Soil and site. A moist soft soil and shady situation, such as is afforded by borders of north exposure is preferable. Miller says, "The fruit is always best when the plants are placed in an open situation, and light loamy soil."”

4714. Final planting. As only a few plants are in general required for private gardens, these may be placed at the distances recommended for gooseberries, in the margin of a shady border, or against a wall of a masonry or open exposure. Neill says, it produces most fruit as a standard, but the largest berries when trained to a wall.

4715. Mode of bearing. The black currant bears chiefly on the shoots of the preceding year, and also from snags or spurs, which, however, are less abundant, and of smaller size in the black currant than in the gooseberry or red currant.

4716. Pruning. Attend to the general directions giving for pruning gooseberries, observing to depend less on spurs than on the preceding year's wood, cutting out the old as it becomes naked and barren, to make room for the new.

4717. Insects and diseases. The black currant is seldom attacked by insects; though, like the elder-tree, it has its own variegated caterpillars, which sometimes reduce it to a state of complete nudity. (4677.)

4718. Gathering the fruit. See Red Currant.

4719. Forcing. The black currant may be forced in pots like the gooseberry. In Russia this is often done for the sake of the fragrance of the leaves.

4680. The red currant is a low shrub, with smooth branches, doubly serrate, pubescent leaves, yellowish-green flowers on pendulous racemes, which appear in May, and the fruit ripens in June and July. The berries of this shrub, in its wild state, are red; cultivation has produced white and pale-red varried berries. It is a native of the northern parts of Europe, and found in hedges and woods in England. Professor Martyn observes, that “the currant does not seem to have been known to the ancient Greeks and Romans, as the southern nations of Europe have not even an appropriate name to it at this day. The old French name groselles d’outrør mer; and the Dutch, beskens oversee, proclaim their having been strangers imported. Our English name of currant is evidently from the similitude of the fruit, to that of the uva cornithica, the small grape of Zante, or the common groers’ corinths, or currants. The red currant has been long cultivated in Britain, and very much improved in the size of the bunch and berry.

4681. Use. The fruit is acceptable at the dessert, being of an agreeable acid taste. It is much used for jellies, jams, and wines. Forsyth says, it is the most useful of all the small fruit, either for the table and kitchen, or for preserving, making wine, &c.; and continues longer in succession than any other. According to Withering, the juice forms an agreeable acid to punch; and Professor Martyn says it was a common beverage in Paris in 1763. Its medicinal qualities are similar to those of other subacid fruits,allsaying thirst, lessening an increased secretion of the bile, and correcting a puritrd and scorbatic state of the fluids.

4682. Varieties. These are —

4683. Propagation and nursery culture. The same as in the gooseberry. With a view to obtaining improved varieties from seed, that indefatigable horticulturist, Knight, procured cuttings, in the year 1816, of the finest varieties of the red and the white currant, which he planted in pots of very rich morros, for a south wall; on which the trees were subsequently trained. At the cend of three years, within which period the pots had been as often changed, the trees were first suffered to produce blossoms. These were, with the exception of a very small number, removed from the white currant trees, as soon as their buds unfolded; and those which remained were deprived of their stamens, whilst immature, and subsequently fertilised by the pollen of the red variety. The seeds thus obtained were sowed in pots, as soon as the fruit had become perfectly mature, and were subjected, early in the following spring, to the artificial heat of a forcing-house; by which means, and by proper subsequent attention, the plants grew more than a foot in height in the first season. At two years old, in the year 1816, several of the plants, and, in 1817, the greater part of them, produced fruit of great variety of character, and merits; but out of about two hundred varieties, only three red and two white appeared to possess greater merits than their parents. (Hort. Trans. ii. 85.)

4684. All the sorts very hardy, will grow freely, and bear plentifully almost any where, alike in open and shady situations, by which the fruit may be obtained early, in June and July, and prolonged for several months in succession till October. As to soil, the currant generally does well in any common garden-ground, well tilled and recruited; it bears the greater crop in a strong loam, or impertinent soils, and is does not mind a sandy light mould, which is not poor. Previous to planting, the ground should be dug two feet deep.

4685. Final planting. “ The season for planting on a dry soil is any time in open weather, from the fall of the leaf till February or March. Plants expected to bear the following summer are best moved in October, and should be well watered before. After a competent supply of standard bushes, to the planted chiefly in the kitchen-garden, in a single row round the main compartments, or in the outward borders, or some in cross rows, to divide extensive compartments. Plant them from five to ten feet distant in the row. To make large slips, all plantations are formed in parallel rows, with intervals between the rows of eight or ten feet, and between the trees in each row of six feet. Where convenient, have also some choice sorts trained against walls or palings, of different aspects, to obtain early and late fruit in perfection; some against a south exposure, for early production; others on east, west, and north walls, for intermediate success and late fruit. Plant them at six, eight, or ten feet distance; let them occasionally fill the vacant spaces between other wall-trees. The branches should be allowed to advance from near the bottom, and be trained in a nearly horizontal direction from three to six inches asunder. Before mailing them, cut out superabundant and irregular growths, retaining a competency of regular shoots for orderly training, and amounting, if any of very considerable length, prune them to moderate extent. Some may likewise be trained as espaliers, in a detached row, in the borders or divisions of the compartments. The trees so trained may either be left to grow without support, or be tied occasionally to stakes, and the shoots which will not overspread the ground. Being kept moderately thin and regular, they will bear fine large fruit, and make an agreeable appearance.”

4686. Mode of bearing. Currant-trees, in general, bear the fruit both on the young wood of one, two, and three years’ growth; and on the older branches, from small spurs, and snags along the sides, which continue several years fruitful, but the fruit produced on the last year’s shoot is always finest, especially when the old mother bearers have borne more than four years.

4687. Pruning. The chief part of the future culture is seasonal pruning. After the plants are furnished with full heads, they produce many superfluous and disorderly shoots every summer, crowding the trees, and keeping them small. The young shoots, and the shoots of the year and old wood The season for the capital pruning is winter; but a preparatory part is performed in summer, to thin the superfluous shoots of the year where too crowded, excluding the sun and air from the first, as to standards:—

4688. Summer pruning. “ In May or June cut out close the most irregular shoots rising in the centre of the tree, with all the cross and water-shoots, to admit more freely the essential influence of the air
Raspberry. — Rubus idaeus, L. (Eng. Bot. 2442.) 

The raspberry plant has stems which are suffrutescous, upright, rise about two feet high, and are biennial in duration; but the root is perennial. The leaves are quininate-pinnate, the flowers come in panicles from the extremity of the present year's shoots; they are white, appear in May and June, and the fruit, which in the wild plant is red, ripens about a fortnight afterwards. It is a native of Britain, and not uncommon in woods in low moist situations.

Use. — The fruit is grateful to most palates, as nature presents it, but sugar improves the flavor; accordingly, it is much esteemed when made into sweetmeats, and for jams, tarts, and sauces. It is fragrant, subacid, and cooling; allays heat and thirst, and promotes the natural excretions in common with other summer fruits. It is much used in distilling, to make the cordial spirituous liquor, to which it gives name. Raspberry-syrup is next to the strawberry in dissolving the tartar of the teeth; and as, like that fruit, it does not undergo the aceto-fermentation in the stomach, it is recommended to gouty and rheumatic patients.

The varieties are —

<table>

PRACTICE but because, when or after the same are cultivated and naturally greater rably they may thrive. All the cranberry fruit is of a very large size. The fruit of the raspberry may be obtained of a very large size, other circumstances being of the most favorable kind, by destroying all the suckers; but in this way, the plant being destroyed, a double plantation is wanted, one to grow only suckers, and the other fruit. In this way Kecht, at Berlin, produces plants ten and twelve feet high, with fruit larger than any we have seen in this country (Versuch den Weinbau, &c. p. 46).

507. Selecting the crop. “The fruit of the different varieties comes in from the end of June or July till October. As it ripens, it should be gathered while immature, for in full age, it will not keep above two or three days before it moids, or becomes maggotty, and unfit to be used.” (Abercrobrum.)

508. The American cranberry (Oxycoccus macrocarpus, P. S.) (Hort. Kev. ii. t. 7.) is a native of North America, and by the ingenuity of Sir George gardens, it may be said to be now added to our cultivated fruits. The plant was known to Miller, who, of the cranberry tribe, in general, observes, “they can only be cultivated for curiosity in gardens, for they will not thrive much, nor produce fruit out of their native swamps and bogs.” A very interesting account of the mode adopted by the illustrious horticulturist above mentioned is given by himself in the Hort. Trans. i. 71. and of the produce, which was large and uniform. In one year, viz. 1813, from three hundred and twenty-six square feet, or a bed about eighteen feet square, three and a half Winchester bushels of
berries were produced, which, at five bottles to the gallon, gives one hundred and forty bottles, each sufficient for one cranberry-pie, from two and a half square feet.

4709. Culture in moist soil. "Wherever there is a pond," Neill observes, "the margin may, at a trifling expense, be fitted for the culture of this plant, and it will continue productive for many years. All that is necessary is to drive in a few stakes, two or three feet within the margin of the pond, and to place the plants between these, so as to prevent the soil of the cranberry-bed from falling into the water; then to lay a parcel of small stones or rubbish in the bottom, and over it peat or bog-earth, to the depth of about three inches above, and seven inches below the usual surface of the water. In such a situation the plants grow readily; and if a few be put in, they entirely cover the bed in the course of a year. They are planted 18 inches apart; or if a bed of bog-earth be sunk in any shady situation, so as its surface may be a few inches below the general level, for the sake of retaining water, the plant will thrive well, and be regularly watered in the driest weather, produce abundant crops.

4711. The common cranberry (Oxycoccus palustris, P. S.) (Eng. Bot. 319.) may be subjected to the same treatment. "Great quantities of this berry are gathered in upland marshes and turf-bogs, both in England and Scotland. The berries are made into tarts, and have the same flavor as the Russian imported cranberries, or those procured by cultivation." (Neill.) Twenty or thirty pounds worth are sold each market-day for five or six weeks together in the town of Langtown, on the borders of Cumberland." (Light-foot.)

4712. The strawberry is a small creeping plant, with a perennial root, and, in general, ternate leaves. There are numerous sorts by some botanists distinguished as species, by others considered as only varieties. Knight (Hort. Trans. vol. iii. 207.) considers the grandiflora or pine, the Chiloensis or Chili, and the Virginiana or common scarlet (the first supposed to be a native of Surinam, the second of Chili, and the third of Virginia,) to be varieties only of one species; as all may be made to breed together indiscriminately.

The fruit has received its name from the ancient practice of laying straw between the rows, which keeps the ground moist and the fruit clean. They are natives of temperate or cold climates, as of Europe and America. The fruit, though termed a berry, is, in correct botanical language, a fleshy receptacle, studded with seeds.

4713. Use. The fruit is fragrant (whence fragaria), delicious, and universally esteemed. It consists almost entirely of matter soluble in the stomach, and neitherthere nor when laid in heaps and left to rot, does it undergo the aceto-saline fermentation. Hence it is very nourishing, and may be safely eaten by gouty and rheumatic persons. "In addition to its grateful flavor, the subacid juice has a cooling quality, particularly acceptable in summer. Eaten either alone, or with sugar and cream, there are few constitutions with which strawberries, even when taken in large quantities, are found to disagree. Further, they have properties which render them, in most conditions of the animal frame, positively salutary; and physicians concur in placing them in their small catalogue of pleasant remedies. They dissolve the tartaraceous incrustations of the teeth. They promote perspiration. Persons afflicted with the gout have found relief from using them very largely; so have patients in cases of the stone; and Hoffman states, that he has known consumptive people cured by them. The bark of the root is astringent." (Abercrombie.)

4714. The species and varieties are —

The wood-strawberry (F. vescum) (Eng. Rot. 1824.) with oval serrated leaves; the fruit round and small, red, white, and green. A native of Britain. The Green Strawberry (F. vescum) (Duch. arb. 1. t. 5.) with leaves like the preceding; the fruit roundish and scarlet-colored. A native of Virginia. Varieties. Early scarlet, Wilmore's late, common late, Wilmore's dwarf (Eng. Rot. 569.)

The Strawberry (F. vescum var.) (Hort. Trans. ii. p. 27.) an Aberdeen seedling, introduced in 1821. Plant 18 in. high; leaves roundish, large; fruit large and roundish, yellow. Commonly cultivated.

The Downton (F. vescum var.) (Hort. Trans. ii. p. 15.) The fruit is large, irregular, and concomitant-like; leaves large; plant hardy and prolific.

The Volunteers (F. Virginica) (Eng. Rot. 1878.) with oval rough-jointed leaves; the fruit large, of a pale red color. Native of North Carolina. Duch. arb. 1. t. 5. 1825.

The Chili (F. chiloensis) (Duch. arb. 1. t. 5.) with oval, thick, hairy leaves and large flowers; the fruit large and red. Native of South America. Keen's imperial, or new Chili (F. Chil. varia) (Hort. Trans. ii. p. 74;) a large showy fruit. Keen's seedling. (Hort. Trans. v. p. 12.)

The pine (F. grandiflora) (Miller, icon. 2. t. 288;) the leaves small and delicate; and covered with a thick white down, or white hair, or greenish-tinted, of this most rich-flavored fruit. South America. Mathew's castle. Princess Charlotte.

The alpine or prostrate (F. collina) which consists of two distinct sorts, one red and white, or greenish-tinted, of this most rich-flavored fruit. South America. Matlock.

The one-leaved (F. monogyna) (Rot. Mag. 63;) the pulp of the fruit pink-colored. South America.

4715. Modes of propagation. "The plants multiply spontaneously every summer, as well by suckers from the parent stem as by the numerous runners; all of which, rooting and forming a plant at every point, require only removal to a bed where there is room for them to flourish. Each of these separately
planted, bears a fine fruit the following season, and will bear in full perfection the second summer. A plantation of the alpine yields fruit the same year that it is made. The woods and the alpine come regular, and the natural method of planting a fine fruit is to remove the plants from offshoots, except the intention be to try for new varieties. Knight, in making experiments, with a view of ascertaining whether most of the sorts would not breed together indiscriminately, raised above four hundred varieties, some very bad, but the greater part of them, and a few very choice, of fruit; and dung, while offshoots were sent to the Horticultural Society in August, 1818, were found of various degrees of excellence. The seeds, if sown immediately after being gathered, will produce plants which will come into bearing the following year.

4717. General culture. The following original and excellent instructions for cultivating the strawberry, are given by Keen, of Islworth; a most successful grower of this fruit. He says, "I will commence with a general detail of my practice: this may be considered as applicable to all the varieties of the strawberry; and afterwards, in noticing each kind that I cultivate, I will specify such peculiarities of treatment as are exclusively applicable to each."

4718. In preparing the soil for strawberries, "if it be new, and, as is frequently the case, very stiff, it should be deeply dug; but if the bottom soil of the ground be light, I recommended only a simple digging, placing dung at the bottom, under the mould so dug; on the contrary, should the land have been kept in a high state of cultivation, or be good to the full depth, it will be advisable for the bottom spit to be brought up to the top, placing the dung between the two spits. The best manner of planting the plants is, by digging out runnels, in the previous season; for it is a very bad plan to supply a new plantation from old plants. With respect to the time of planting, I have always found the month of March better than any other. Sometimes, when my crops have been held back by the weather, and the plants have been planted in the autumn, for the following year, but these have always disappointed my expectations. I plant them in beds, containing three or four rows, and the plants, in each row, at a certain distance from each other, leaving an alley between each, the distance of the rows and of the plants in the rows, as well as the width of the alleys, depending on the kind of strawberry plant, and the distance of the beds, as it will afterwards be stated, may appear considerable; but, I assure you, inter 

4719. General culture. After the beds are planted, I always keep them as clear of weeds as possible, and on no account allow any crop to be planted between the rows. Upon the growing of the runners, I have them cut when necessary: this is usually three times in each season. In the autumn, I always have the beds cleared, and, for I find that a well-cultivated bed produces the plant, and that the fruit is injured, that allowing this space for the workmen to stand on, when they water the plants, or gather the fruit, is beneficial, because I have observed in other persons' grounds, where less space is allotted for this purpose, that great damage is done to the plants and fruit by the trampling of the people.

4720. Sorts grown by Keen. The pine Keen grows in a light loam, "though no other kind of strawberry will bear a strong loam better than this. It is likewise to be noticed, that this is of all others the most difficult strawberry from which to procure a good crop. Particular care must be taken that they are planted in open ground; for in small gardens they grow very strong, but seldom bear fruit, in consequence of being so much shaded by standard trees; and I have observed the shade of the walnut-tree to be much more injurious to these than to others: for under it they seldom bear at all, but run entirely to leaf. In planting the beds of pines, I keep the rows two feet apart, and put the plants eighteen inches from each other in the row, leaving alleys of three feet wide between each bed; these large distances I find necessary, for the trusses of fruit in my garden-ground are frequently a foot long. The duration of this strawberry, with me, is three years: the first year it bears the best, the second year the crop is very good, and the third year it is less."

4721. The imperial strawberry, "which was raised by myself from seed, may be treated in a similar way, with respect to planting, distance, &c. as the pine; but I have to remark, that it requires rather a lighter soil, and is not so averse to run to leaf as the pine." 4722. The scarlet strawberry must be treated also like the pine. "With respect to distance for planting the beds of scarlets, I put each row twenty-one inches apart, and each plant eighteen inches distant in the row; thus an alley of six feet six inches wide. The duration of this strawberry, with me, seldom exceeds three years."

4723. The hautboy. "I have always found to thrive best in a light soil: and it must be well dug, for excess of manure does not drive it into leaf like the pine-strawberry. In planting the beds, each row is two feet apart, and each plant eighteen inches distant in the row, and an alley of six feet six inches wide. There are many different sorts of hautboys: one has male and female plants in the same blossom, and bears very freely; but that which I must approve, is the one which contains the male organs in one blossom, and the female in another; this bears fruit of the finest color, and of far superior flavor. In selecting these plants, care must be taken that there are not too many of the male plants among them; for as these bear no fruit, they are apt to make more runners than the females. I consider one male to ten females the proper proportion for an abundant crop. I
learned the necessity of mixing the male plants with the others, by experience, in 1809; I had, before that period, selected female plants only for my beds, and was entirely disappointed in my hopes of a crop. In every garden, the error was repeated, and I planned and planted beds, with a lead, of female half-toutes. In a few days, I perceived the fruit near the bottle to swell; on this observation, I procured more male blossoms, and in like manner placed them in bottles, in different parts of the beds, removing the bottles to fresh places every morning, and by this means obtained a moderate crop where I had gathered no fruit the preceding year. The duration of the halfouty, with me, seldom exceeds three years.”

4754. The wood-strawberry is best raised from seed, “ which I obtain from fruit just gathered, sowing it immediately on rich earth in a bed of rich earth, 12 inches deep. In beds, the plants are of a proper size, I transplant them into other beds, where I let them continue till the March following. They are then planted in rather a moist soil, in beds, as the others, each row being two feet apart, and the plants in each row eighteen inches distant, the alley between each bed being three feet wide: in this way I produce abundant crops of very fine fruit from the strawberries, and runners, but never with such good success as from seeds, particularly if the runners were taken from old roots. The duration of this strawberry, with me, seldom exceeds two years.”

4755. The alpine strawberry must always be raised from seed, which should be sown in a bed of rich earth in the spring. “ When the plants are of a proper size, which will be in July or August, I plant them in rows at the back of hedges or walls, in a rich, or in a very moist soil: the rows should be two feet apart, and the distance, from plant to plant, in the rows, twelve inches. My alpines, this year, thus managed, are bearing most abundantly, so much so, that in gathering them there is not room for the women to set their feet, without destroying many. The alpines differ from all other strawberries in quickness of bearing; for no other sort, sown in the spring of the year, will produce fruit, under two years, whereas this yields a crop at the end of one year. Its duration, with me, seldom exceeds two years, and frequently it lasts only one year.” (Hort. Trans. ii.) Williams considers that the fruit of plants raised from seed, comes in very well as a late autumn crop, but is certainly inferior in flavor to that produced from transplanted runners. (Hort. Trans. i. 241.)

4756. The Rev. T. Garnier, a successful culturist of strawberries, never suffers any of the varieties to remain upon the ground more than three years. “ Early in August, or as soon as the gatherings are over, I destroy all my beds, and proceed immediately to trench, form, and manure them in the manner before directed, to receive the plants for the crop of the ensuing year, taking care to select for that purpose the strongest, and best-planted plants of the present year’s crop. This season the weather should be particularly hot, and the surface of the ground much parched, I defer the operation of preparing my beds and planting them till the ground is moistened by rain. Such is the simple mode of treatment which I have adopted for three successive years, and I have invariably obtained upon the same spot, a great produce of beautiful fruit, superior to that of the other gardens in the neighborhood. Depth of soil I have found absolutely necessary for the growth and production of fine strawberries, and when this is not to be obtained, it is useless, in my opinion, to plant many of the best varieties. It is not generally known, but I have ascertained the fact, that most strawberries generate roots, and strike them into the ground, nearly two feet deep, in the course of one season. The line and roseberry succeed better than any other in stiff, and shallow soils, but they should always be planted in an open situation, and not, as is too commonly the practice, in shady and neglected parts of the garden.” (Hort. Trans. iv. 480.)

4757. I observed, in raising strawberries, the danger of blameworthy cutting over the leaves of strawberries after they have borne a crop, thereby preventing proper buds being formed for next year, and also depriving the roots of the plants of their natural protection from the frost. He is also adverse to the practice of digging between the rows in winter, which, he says, cuts off the fibrous roots, and prevents the plants from setting out in spring with vigor. Another error in which they are often indulged is that of lighting in a bottle on the plants, which is a very great error, and I have a great objection to the practice of planting in water, and placing stones, or pieces of brick, over the plants. (Caled. Hort. Soc. Mem. iii. 291.)

4758. Brick-beds for strawberries. These were observed in a small garden near Chatham, and are thus described: “The beds (fig. 497. a) were upon flat ground, each about three feet wide, and between them were trenches about nine inches wide, and four-inch walls of brick on each side of the trenches (b), to keep up the earth on the sides of the beds. These trenches were about the depth of two or three courses of bricks laid flat, without mortar, and were intended for the purpose of holding water, which was supplied from a pump whenever the ground was dry, while the plants were in fruit. By this method, a much greater crop of fruit was obtained, and the plants continued bearing much longer than in beds where there were no trenches for water. In Devonshire, strawberry-beds are constructed against a side of a hill or bank, by building up beds in steps, with rough granite at the front, to keep up the earth, each step being about two feet high and three feet wide. These steps were filled with good loam, and the surface of each was covered with rough pieces of granite bedded into the loam, leaving openings between the stones, just sufficient to permit in the plants. The surface being covered with granite, kept the ground longer in a moist state, and the fruit always clean. “ I should expect,” observes the writer, “that chippings of stone, such as may be had from the masons in London, might answer the same purpose. I have found a great advantage in keeping the fruit clean, by laying a row of common bricks on each side of the rows of strawberry-plants; I tried plain tiles, but found bricks answer better, as the tiles are apt to be broken in gathering the fruit, and will not do to use a second time.” (Atkinson, in Hort. Trans. v. 191.)

4759. Taking the crop. The fruit ripens from June to August and September; but the main crop is usually over in July. Gather when the weather is dry, and the same day that the fruit is to be sent to table, otherwise it will soon lose its flavor. Finch off the calyx and a quarter of an inch of the peduncle, along with the berry. 3 3 3
4730. To have a regular succession of strawberries throughout the autumnal months. This is commonly done by means of the walnut and alpine species, and their varieties. Garnier thinks it may be accomplished by late planting; for example, of Wilmot's late scarlet, or the common scarlet about May. He has planted runners of the roseberry on the 1st of July, and gathered them from the 7th of September to the 1st of November. (Hort. Trans., viii. 472.)

4731. For forcing the strawberry, see Chap. VII. Sect. VIII.

Sect. IV. Nuts.

4732. Among nuts the most useful in this country is the walnut, both for the dessert and pickling; the filbert is also a very useful fruit; chestnuts are wholesome and nutritious, and, in form, in Spain and Italy, an important article of human food.

4733. The walnut is a large and lofty tree, with spreading boughs, and pinnate leaves, having a very strong aromatic odor. The male flowers come in subterminating aments; the females scattered two or three together in close sessile buds on the young wood near the extremities of the branches. The fruit is an ovate, coriaceous, smooth drupe, enclosing an irregularly grooved nut, which contains a four-lobed oily eatable kernel, with an irregular knobbed surface, and covered with a yellow skin. The flowers are produced in the end of April and beginning of May, and the fruit ripens in September and October. It is a native of Persia and the south side of Caucasus; but it is supposed to have been introduced here from France, and called gaul-nut, before 1562.

4734. Use. The kernel, when ripe, is in esteem at the dessert; and the fruit whole, in a green state, before the stone hardens, is much used for pickling. An oil which supplies the place of that of almonds, is expressed from the kernel in France. In Spain they strew the gratings of old and hard nuts, first peeled, into their tarts and other meats. The leaves strewed on the ground and left there annoy worms; or macerated in warm water, afford a liquor which, from its bitterness, may effect their death. The unripe fruit is used in medicine for the same purpose. Pliny says, "the more walnuts one eats, with the more ease will he drive worms out of his stomach." The timber is used in this country for gun-stocks, being lighter in proportion to its strength and elasticity than any other. It is almost exclusively used in cabinet-work in most parts of the country. The young timber is held to make the finest-colored work, but the old to be finer variegated for ornament.

4735. Varieties. Those commonly cultivated for their fruits are—

4736. Propagation. It has generally been propagated from the nut; and this mode is recommended by Knight, probably from the fact that it has not yet been found by inoculation as practised successfully by Knight. Inarching this tree was long ago recommended by Bouchter, who says, "he found the fruit in this way produced in one third of the time necessary for plants raised from the nut."

4737. Knight, "having planted, in the spring of 1799, some walnut-trees of two years old in garden-pots, raised them up to the bearing branches of an old walnut-tree, and grafted them, by approach, with parts of the bearing branches of the old tree. An union took place during the summer, and in the autumn the grafts were detached from the parent stem. This was accomplished in a nursery, and, without any peculiar care or management, produced both male and female blossoms in the third succeeding spring, and have since afforded blossoms every season." (Hort. Trans. i. 61.) After numerous trials, he also succeeded in propagating the walnut-tree from budding. "The buds of trees," he observes, "of almost every species, succeed with most certainty when inserted in the shoots of the same year's growth; but the walnut-tree appears to afford an exception; possibly, in some measure, because its buds contain within themselves, in the spring, all the leaves which the tree bears in the following summer. This circumstance ceases its importance when large shoots whose live buds and dead buds of each season are also, consequently, very nearly of the same age: and long before any have acquired the proper degree of maturity for being removed, the annual branches have ceased to grow longer, or to produce new foliage. To obviate the disadvantages arising from the preceding circumstances, I adopted means of retarding the period of the vegetation of the stocks, comparatively with that of the bearing tree; and by these means I became partially successful. There are at the base of the annual shoots of the walnut and other trees, those which join the year-old wood, many minute buds, which are almost concealed in the bark, and which rarely or never vegetate, but in the event of the destruction of the larger principal buds which occupy the middle part of the end of the annual wood, by inserting in each stock one of these minute buds, and one of the large and prominent kind, I had the pleasure to find that the minute buds took freely, whilst the large all failed without a single exception. This experiment was repeated in the summer of 1813, upon two or three plants which grew in a place that had been placed, during the spring and early part of the summer, in a shady situation under a north wall; whence they were removed late in July to a forcing-house, and instantly budded. These being suffered to remain in the house during the following summer, produced from the small buds, shoots nearly three feet long, terminating in large and perfect female blossoms, which necessarily proved abortive, as no male blossoms were procurable at the early period in which the female blossoms appeared: but the early formation of such blossoms sufficiently proves that the habits of a bearing branch of the walnut-tree may be transferred to a young tree by budding, as well as by grafting by approach. The most eligible situation for the insertion of buds of this species of tree (and probably of others of similar habits) is near the summit of the wood of the preceding year, and of course, very near the base of the annual shoot; and if buds of
The small kind mentioned be skilfully inserted in such parts of branches of rapid growth, they will be found to succeed with nearly as much certainty as those of other fruit-trees, provided such buds be in a dormant state, and those of the chestnut being deciduous is decided to be preferred. 4729. *Carville* (Hort. Trans. i. 62.) mentions the case of a walnut-tree raised from the nut in the usual way, on a light soil, on a sandy sub-soil, and in a warm sheltered situation, which produced fruit in six years; but the first year of life is said to be barren.

4730. *Acerirenovale* says, the walnut-tree is propagated, in general, by sowing well ripened nuts of the finest varieties: but as seedlings are apt to vary, new plants are occasionally raised by layers and inarching, to continue particular sorts permanent. The nuts may be sown in autumn or spring, in drills, nine to ten inches deep; placed about two inches asunder, and having earthed them in, smooth the surface. They will come up in the spring. When of one year's growth, set out the plants in nursery rows, a foot asunder by six inches in the rows, to remain two years, then to be transplanted (doubling the distance) into other nursery lines. Transplant each with a single stem of six or seven years' height; then to be permitted to remain asunder, and form a spreading head. Layers may be made, in autumn or spring, of young shoots produced near the ground from proper stools formed for that purpose: they will be rooted in one season, to plant off in nurseries rows for training as above. Inarching may be performed in February or March upon seeding walnut-stocks, advanced in proper stumps.

4740. *Soil and site.* The walnut-tree will succeed in any common fertile soil, a light or a clayey loam, as the sub-soil to be dry, and the site a little sheltered; but it thrives best where there is a good depth of loam mixed with sand or gravel rather than clay. As this tree is long before it bears fruit, there is a particular inducement for procuring plants from the nursery, either inarching, budded, or in as advanced a stage as it will be safe to remove them at. This may be when they are from eight to twelve years old, according as they may have been prepared by repeated transplantations. Walnut-trees may be planted in orchards or small paddocks, in a row towards the boundaries; or in parallel double rows in a quincunx order, in extensive grounds, but detached from fruit-trees of more contracted growth. The line of walnut-trees, when fully grown, will serve as a screen to the fruit-trees occupying the interior ground. The plants should stand at twenty-five and the trees to fifty feet distance.

4742. Pruning. Walnut-trees, when finally planted, may be permitted to branch out in their natural order, with the exception of a little occasional pruning, to regulate any casual disorderly growth, to reduce over-extending branches, and to prune up the low stragglers. Pruning is undertaken by the Baron Tschoudi, near Metz, in Lorraine. A zone of bark two inches broad is taken out, and the part plastered over with cow-dung and loam; the consequence is that the trees prove more prolific, and the fruit ripens sooner.

4745. *The chestnut.*—The chestnut is a large tree, spreading its branches freely on every side where it has room, but, planted closely, will shoot up straight to a great height. The leaves are lanceolate, serrated, and very large. The aments, or catkins, of male flowers are pendulous at the ends of the branches; very long, resembling those of the walnut. They have a strong spermatic smell; the flowers are collected in remote little balls, and are sessile. The proportion of male flowers to the females is prodigious. The calyx of the female flowers becomes a ciliate capsule or four valves, of a silky smoothness in the inside, and containing two or three nuts or one only. It flowers in May, and ripens its fruit in October. It is supposed to have been originally brought from Sardis to Italy by Tib. Caesar. It is so common as to be considered a native in France and Italy; and some consider it as naturalised in England, though it is not likely to propagate itself in this country. Some of the oldest trees in the world are of this species; as that mentioned by Brydone on Etne, and the great tree at Tortsworld in Gloucestershire.

4746. Use. The fruit is a desirable nut for autumn and winter, and is eaten roasted, with salt, and sometimes raw. Abroad, it is not only boiled and roasted, but puddings, cakes, and bread are made of it. "Chestnuts stewed with cream," according to Phillips (Pomarium Brit. 55.), "make a much admired dish, and many families prefer to them all other stufings for turkeys." He says, "I have had them stewed and brought to table with salt fish, when they have been much admired." The timber was formerly in very general use in house-carpen try, though some, with every appearance of reason, consider what is generally called old chestnut as old oak.

4747. *Varieties.* There are none of any note. Some varieties ripen their fruit a few days earlier than others, but none of these have been fixed on and perpetuated by the nurserymen so as to be rendered available by purchasers.

4748. Propagation. Military and most gardeners recommend propagation from nuts; but, for fruit, the Dutch process of grafting is decidedly preferable. Sir Joseph Banks says, "the nurserymen there deal in grafted chestnut-trees; and we may add, that they are now to be had in the London nurseries. (Hort. Trans. i. 62.) Knight says, "The Spanish chestnut succeeds readily when grafted in almost any of the usual ways, and when the grafted limbs are well secured before the spring. Grafting this tree, in the spring, is a much admired practice, and I am much inclined to think, from experiments I have made on this tree, that selecting those varieties which ripen their fruit early in the autumn, and by propagating with grafts or buds from young and vigorous trees of that kind, which have just attained the age necessary to enable them to ripen the fruit, it may be cultivated with much advantage in this country, both for its fruit and timber." (Hort. Trans. i. 62.)

4749. *Soil and site.* The tree prefers a sandy loam with a dry bottom; but will grow in any soil on a dry sub-soil. Distribute the plants towards the northern boundary of orchards; and in larger groups, over any vacant tracts in extensive pleasure-gounds or parks, and to form spacious avenues, or a row along any out-boundary. A great number should not be placed close to a residence, as the smell of the flowers is offensive. Plant them at not less than thirty feet, and thence to fifty feet distance.
PRACTICE and THE.

4752. The common hazel-nut, or the filbert in its wild state, is a large-sized shrub, with an ash-colored bark, and alternate roundish cordate leaves. The male catkins appear on the preceding year's shoots in autumn, and wait for the expansion of the female gins in the spring. It is a native of Britain, very common in most woods, and extensively cultivated about Maidstone, in Kent.

4753. Use. As a table nut it is in universal esteem; and the wood and twigs of the wild plants are used for sticking peas, forming pegs, number-sticks, staking green-house plants and raspberries, and many other similar purposes in gardening.

4754. Varieties. These are—

</tr>
</thead>
</table>

4755. Estimate of sorts. The common wood-nut, the least desirable for horticultural plantations, may be admitted for variety, and its returns are very profitable. The filbert is a free-blooming shrub, and it has the advantage of having a shell which, with a thick shell, but the kernel is considerable in size, and sweet. The Barcelona, a good large nut, with a thin shell, is well known, great quantities being imported as well as grown here. The long native nuts seldom kernels well. The cossford is very sweet, kernels well, and the tree is a great bearer.

4756. Soil and situation. A cool or dry soil is well adapted to filbert and nut trees in general; for example, a sandy loam, mixed with minute shattery stones or grit, and with a low proportion of vegetable or animal remains; for the plants fruit best when but moderately strong. About Maidstone it is usual to have a hazy loam of some depth, on strong, level soil, which they dress every year, as the filbert requires a considerable quantity of manure. They are generally planted in the orchard, or in the slips which surround the kitchen-garden.

4757. Propagation. All the sorts can be propagated by grafting, by layers, by suckers, and by sowing. The least desirable method is by sowing. They are propagated in this country because they will not keep the result; but in America, by either grafting them in February or March upon seedier or sucker stocks of the filbert or hazel; or by layers of the young wood in the spring. Sow the nuts in October or November, or in the spring, in a light earth, covering them with six inches. The greater part will germinate in spring, and when the plants are one or two years old they plant them out in nursery lines in autumn or spring. They train a principal supply in standards, half-standards, and dwarf standards, each with a single clean stem, from six feet high down to twelve inches.” (Abercrombie.) About Maidstone, according to Williamson, they are almost universally propagated by suckers.

4758. Mode of bearing. All the species bear principally upon the sides and ends of the upper young branches; and from small shoots, which proceed from the bases of side branches cut off the preceding year.

4759. Final planting. “The season for planting all the sorts is autumn or spring, or any interval in mild weather from October till the beginning of March. Allot detached standards, not less than ten, and thence to twenty feet distance, to have room to branch out in full heads. In the filbert-grounds about Maidstone it is usual to plant hops, standard apples, and cherries among the filberts. When the filberts come into a bearing state the hops are destroyed, and the fruit trees only suffered to remain. The ground is then planted with gooseberries, currants, &c. and herbaceous vegetables.” (Hort. Trans. iv. 152.)

4760. Culture. “In the filbert-orchards, about Maidstone, in it is a prevailing practice to train the trees with short stems, like a gooseberry-bush, but with heads in the shape of a punch-bowl, and extending thin of wood, and to prune them with exact attention to the mode of bearing. The filbert is there propagated by suckers, and Williamson advises to plant them where they are to remain; to add to them, without rivalry, for three or four years; and then to cut them down within a few inches of the ground. They will push five or six strong shoots which, the second year after cutting down, are to be shortened one third. Then place a small hoop within the branches, and fasten the shoots to it at equal distances. In the third year, a shoot will spring from each bud; these must be sufficiently far from each other. In the fourth year, when they are to be cut off, nearly close to the original stem, and the leading shoot of the last year shortened two thirds. In the fifth year, several small shoots will arise from the bases of the side branches, which were cut off the preceding year; from these, slips may be expected to be exhibited; and the future order of the trees will be seen from the annual supply of these by cutting out all that have borne fruit. The leading shoot is every year to be shortened two thirds or more, and the whole height of the branches must not be suffered to exceed six feet. Every shoot that is left to produce fruit should also be tipped, which prevents the tree from being exhausted. The filberts are planted at the time of planting orchards, in pruning early in spring, to have a large supply of male blossoms and to eradicate all suckers.” Such is the Maidstone practice, which “has been long cultivated;” by which 30 cwt. of nuts per acre have been grown on particular grounds, in particular years, but 20 cwt. is considered a large crop, and rather more than half that quantity the usual one, with a total failure one year out of five, and only as much as the average produce is not less than 5 cwt. per acre. Williamson thinks the failure, happening so often, may be owing to the excessive productiveness of the successful years owing to the mode of pruning, by which “the whole nourishment of the tree is expended in the supply of that year’s fruit.” Hence the yields have been very large here, but not from experiments in his own garden, thinks a regular crop in succession will thereby be obtained. (Hort. Trans. iv. 154.)

4761. Insects. The leaves are little troubled with verdigris or aphides; but the eggs of the weevil (Curculio nucum) (fig. 484 a) and C. pyri (b) are deposited in the granen, and nourished on the kernel, which effectually destroy. The only way of lessening this evil is by taking care to de-
strew all the nuts so infested, in order that the larvae may never attain to the fly stage.

4763. The Ren. G. Sawynce having had a plantation of filberts, which for the 50 years of their existence had produced very little fruit, began to suspect a want of male blossoms. He therefore selected a number of catkins from the common hazel, and suspended them over the scarlet blossom of his filberts; and the result was, that the first year he had more fruit than he had during the 50 preceding years. To prove that it was owing to the farina of the male blossoms, he tried some with and some without this assistance, and found the fruit produced as the male blossoms applied. He taught this mode to a neighboring farmer's wife who had a row of wild trees, and she was "much delighted" with the plan; put it in execution the next day, and the same season sent her instructor 6 lbs. of very fine filberts from four old stunted trees that had not borne one for many years. (Hort. Trans. v. 316.)

Sect. V. Native, or neglected Fruits, deserving Cultivation.

4764. Though some of our native fruits recommend themselves by their already known utility, as the cranberry; yet others, as the sorb, haw, &c. are only mentioned with a view of directing scientific horticulturists of leisure and means, to try what can be done in improving them. We shall enumerate them in the order of stone-fruits and berries.

4765. The sloe is the Prunus spinosa, L. (Eng. Bot. 842.) Icos. Mong. L and Rosacce, J. Ripe, it makes an excellent preserve; urine, the insipissated juice forms the German accacia, and afford an almost indelible ink used to mark linens. It is used in home-made wines, to communicate the color and roughness of red port; and the leaves are employed to adulterate the teas of China. There are two sorts, one the male of the plum (P. insitia), and all the varieties of the common plum (P. domestica). As a shrubbery plant the sloe is most ornamental, blossoming before all others of the prunus tribe.

4766. The bird-cherry is the Prunus padus. (Eng. Bot. 135.) The fruit is nauseous to most palates; but infused in gin or whiskey it greatly improves these spirits, and is only surpassed by an infusion of peach-leaves. A few trees therefore are desirable, especially in Scotland and Ireland.

4767. The mountain-ash is the Sorbus Aucuparia, L. Pyrus Aucuparia, E. B. (Eng. Bot. 337.) Icos. Di- Pent. L and Rosacce, J. The berries are eaten in some parts of Scotland and Wales, and afford an agreeable fermented liquor, and, by distillation, a strong spirit. Grafted on the service-tree, as is frequently done in France, the fruit is said to become larger and more abundant. (Nell, in Hort. Tour, 364.)

4768. The wild service (Pyrus tortuosa, W.) (Eng. Bot. 258.) (fig. 490.), the bastard service (P. pin- natifida, E. B.) (Eng. Bot. 333.) (fig. 500.), and the white-ash-tree (P. Aria) (Eng. Bot. 1838.), afford agreeable mealy berries, with much less acid than those of the mountain-ash. These trees are most ornamental in shrubberies or on lawns; and the two last are not undeserving a place in orchards.

4769. The tree-currant (Ribes spicatum, L. (Eng. Bot. 1290.) Pentand. Mong. L and Ceci, J.) affords a fruit somewhat smaller and more acid than the common red currant; but by crossing and cultivation might, no doubt, be greatly improved; and from its comparatively tree-like habits, might be a more convenient fruit-shrub in respect to crops below or around it.

4770. The common bramble, Rubus fruticosus, L. (Eng. Bot. 715.) Icos. Polyg. L and Rosacce, J. The fruit is powerfully acid and astringent, forms agreeable pies and tarts, medicinal gargles, and also may be used raw. There are two different varieties, the white-fruited and smooth, and one with double blossoms.

4771. The cloud-berry, Rubus Chamaemorus, L. (Eng. Bot. 716.) (figs. 20. and 501.) "In Scotland," Nell observes, "the fruit is also called roe-huck—berries or knot-berries, and they are perhaps the most grateful and useful kind of fruit gathered by the Scots Highlanders. On the sides and near the bases of the mountains it may be collected for several months. It is not cultivated without difficulty, and it seldom yields its fruit in a garden." By raising from roots, and again from the seeds of plants so raised, and so on for six or eight generations, perhaps at the same time crossing the flowers with those of the bramble or raspberry, in all probability this plant might become a valuable accession to the kitchen-garden. Its berries are ripe in September. (See a curious paper in Caled. Hort. Mem. i. 335.) In Lapland and Sweden the fruit is much prized, and used for a great variety of purposes. Dr. Clarke, as we have seen (349.) found it medicinal. (Scandinavia, chap. xvi.)
4772. The dwarf crimson bramble (Rubus arcticus) (Eng. Bot. 1383.) (fig. 504.) produces an excellent berry, found only on the highest and wildest mountains of Scotland. By successive sowing of the seeds on different levels, doubtless it might be brought down, step by step, to live and produce fruit on plains, and in appropriate parts of gardens.

4773. The dewberry (Rubus caesius) (Eng. Bot. 526.) (fig. 503.), the stone-bramble (Rubus sasitius) (Eng. Bot. 2233.) (fig. 504. a), and the up-right bramble (Rubus suberectus) (Eng. Bot. 2572.) (fig. 504. b), afford agreeable acid and aromatic fruits, which come in late in the season, and merit attempts with a view to accommodating them to habits of cultivation. The same remarks will apply to a plant common in the woods of Russia and Poland, and which Dr. Clarke has figured, and named Cripisia; but which appears to be a species of rubus, and probably a variety of R. suberectus.

4774. The snowberry is the Gaultheria serpyllifolia, L.; Vaccinium hispidulum, L.; and Chloigenes of Salisbury. (Mich. Am. i. t. 23.) Decan. Monog. L. and Ercine, J. “Atshaw-hill, near Halifax, it produced fruit abundantly, planted under a north wall, shaded behind by high trees, in a border of sandy peat; and it succeed-ed pretty well in nearly a similar situation at Chapel Allerton, during the eighteen years of my residence at that place, often ripening its berries; but they being little esteemed, I only preserved a patch of it as a rare plant. The flavor of the fruit, however, is exceedingly agreeable to some persons, being strongly perfumed, like eau de noyaux, or bitter almonds, and mixed with a pleasant acid. I now regret that I never tried the berries baked with sugar in a tart; if gathered before they are too soft, they may, no doubt, be preserved in bottles, like cranberries, and possibly prove a valuable addition to our winter fruits of that sort.” (Salisbury, in Hort. Trans. vol. ii.)

4775. The purple or common bilberry, blackberry, or whortleberry, (Vaccinium Myrtillus, L.) (Eng. Bot. 450.) is another bog-plant common in Britain and the north of Europe. The berries are gathered in autumn for making tarts; in Devonshire they are eaten with clotted cream; in Poland they are ripe in July, and, being mixed with wood-strawberries, and eaten with new milk, are considered a great delicacy. In the Highlands of Scotland they are eaten with milk, and made into jellies. They may be successfully cultivated in a shady border of bog-earth.

4776. The red bilberry, or crowberry, Vaccinium Vitis Iidea, L. (Eng. Bot. 580.) The fruit is acid and somewhat bitter, but makes a very good rosb or jelly, which in Sweden is eaten with all kinds of roast meat, and forms a sauce for venison, which is thought superior to currant jelly. In Wales we have experienced it to be an excellent addition to roast mutton. It may be cultivated in a moist shady border of bog-earth, like the common bilberry.

4777. The broad-leaved whortleberry (Vaccinium aquum, L.) (Bot. Rep. 138.) is cultivated at Englıen, in the Due d'Aremberg's garden, and the fruit used in the same way as the cranberry. (Neld, in Hort. Tour, 322.)

CHAP. X.

Horticultural Catalogue. — Exotic Fruits.

4778. Among exotic fruits we comprehend such fruits as require the aid of artificial heat to bring them to perfection, and among these we have included the vine and the fig; for though these fruits ripen in the open air in very favorable situations and warm seasons, yet it is allowed on all hands, that in by far the greater number of situations and seasons grapes and figs, grown in the open air, do not attain any thing like their proper size and flavor. Exotic fruits may be arranged as follows: —

4779. Those in general cultivation; as the pine, vine, fig, melon, and cucumber.
4780. Those well known, but neglected, as such; as the orange, pomegranate, olive, Indian fig, torch-thistle, and strawberry-pear.

4781. Those little known, some of which seem to merit cultivation; as the akee-tree, alligator-pear, anchovy-pear, durion, guava, granadilla, jamrosade, malay apple, leechee, loquat, mango, mangosteen, pishamin, and various others.

4782. The varieties of some of these species, as the vine, fig, and melon are very great; in making a selection we would recommended the plan submitted as to the selection of hardy fruits. (4367.)

SECT. 1. Exotic Fruits in general Cultivation.

4783. The exotic fruits in general cultivation include the three first fruits in the world; the pine-pre-eminent for its flavor; the vine, for its generous and enlivening juice; and the melon, approaching in flavor to the pine. All circumstances considered, it is doubtful if the durion, mangosteen, and other Indian fruits, equal these; certainly no fruit hitherto discovered in any region surpasses the pine-apple.

4784. The pine-apple is described in Miller's Dictionary (art. Bromelia), as herbaeous; but it is by others considered as a shrub. Its common name of pine-apple is supposed to be derived from the resemblance of the fruit in shape to the cones of some species of pine-tree. In richness of flavor this fruit stands unrivalled; and, as Neill observes, "it is one of the greatest triumphs of the gardener's art, to be able to boast that it can be produced in Britain in as high perfection as in a tropical climate." The leaves of the pine-plant are long, narrow, channelled, and in general furnished with spines or prickles on the edges. The flowers are in a loose spike, on a scape, which is leafy at top; as the spike ripens, it takes the form of a fleshy scaly strobile, vulgarly called the fruit, and composed of many coadunate berries, which have scarcely any cells or seeds." Professor Martyn doubts whether there may not be some of the fruits with male flowers only, and others with hermaphrodite flowers; "because those fruits which have seeds are remarkably different from the others when cut through the cells, in which the seeds are lodged; for in these they lie near to the centre of the fruit, whereas in those which have abortive cells, they are chiefly close to the rind." South America is generally considered the native place of the pine, though it is indigenous in uncultivated places in Africa, in great abundance. Linnaeus ascribes it to New Spain and Surinam; and Acosta says, that it was first sent from the province of Santa Croce, in Brasil, into the West, and afterwards into the East Indies. Professor Martyn thinks it may be common to the tropical parts of the three continents. The pine-plant has been long cultivated in Jamaica and other West India islands with great success, and was introduced to the gardens of Europe by Le Cour, of Leyden, about the middle of the seventeenth century. This gentleman, Miller informs us, received his first plants from America, and after a great many trials with little or no success, did at length hit upon a proper degree of heat and management, so as to produce fruit equally good (though not so large; as that which is produced in the West Indies)." From Le Cour "our gardens in England were first supplied with this king of fruits;" and it is "commonly said that Sir Matthew Decker, of Richmond, was its earliest cultivator;" but, as a botanical plant, it was introduced so far back as 1690, by Bentick. (Hort. Kew.) Miller informs us, that at first the plants were kept in dry stoves, during winter, placed on scaffolds, after the manner in which orange-trees are placed in a green-house; and that in summer, they were removed to hot-beds of tanners' bark, under frames. They soon, however, began to erect "low stoves," called succession-houses, and bark-pits under deep frames, for the suckers and crowns. Bradley informs us, that by the year 1730, pine-stoves of the different kinds were established in all the principal English gardens; and Justice, in his British Gardener's Directory, published in 1744, states, that pine-apple stoves had also been erected in Scotland, and he gives the plan of one erected by him in his own garden at Chrichton, near Edinburgh, in the year 1732, in which the pine was fruited for the first time in Scotland. He recommends such as intend cultivating this fruit, to get their plants and furnaces (the latter cast in one piece) of Scott, of Turnham Green, London, and their thermometers from Coles, in Fleet-street.

4785. Use. It is the first of dessert-fruits; and is also preserved in sugar, and made into marmalades and other confectionaries. In preparing to eat this fruit, first twist out the crown and then cut the fruit into horizontal slices: these being served, the rind and scales of the pips are pared off by the guest with a knife and fork. (Speechly.)

4786. Varieties There are many varieties of this fruit, independently of some distinct species, as the B. Penguin and B. Karatas; the fruit of these species being sometimes eaten in the West Indies. If the seeds of the ananas were sown frequently in their native country, Professor Martyn considers that varieties might be rendered as nu-
merous as those of the apple and pear. Miller, in sowing the seeds, found a variety of sorts produced from the same fruit; and Speckley mentions, that he raised in 1768 above seventy plants, from seeds sent to the Duke of Portland from the West Indies, most of which varied in a distinctive circumstance, either in their leaves or fruit. Many of these fruits turned out of inferior quality, probably from the seeds having been gathered indiscriminately. Seeds are not usually produced in this country; when they occur it is generally in those pines which blossom in August, and ripen their fruit in December. (Buck, in Hort. Trans. iv. 535.) The most esteemed varieties in present cultivation are—

The old queen. Fruit oval-shaped, and of a dark yellow hue; the flesh a hard, rather bitter kind, and fruited in fifteen or eighteen months, being about the size of a large pea. It is often weighed from three to four pounds. It is much more common of showing fruit at a proper age and season than most of the other sorts, and has a just preference in most hot-houses. Ripley’s new queen. A variety of the old queen, with a large elegant fruit; fruited also in an equal short period.

Weidick seedling; fruit small, generally broader at the head than at the base; of a pale yellow, or sulphur color, with very flat pips; flesh white and tender, rich in flavor, with less acidity than is Southern Queen. (Hort. Trans. iv. 213.)

Prickly. Brown sugar-leaf. Cone-shaped, and dark-colored till it ripens; leaves large, sour with black and purple tints.

Prickly stuck sugar-leaf. Cone-shaped, the fruit of a golden color, the leaves striped with black and purple tints.

Smooth stick sugar-leaf, similar to the above, but different from it.

Havannah. Tankard-shaped; dark-colored with black and purple tints.

Montserrat. The leaves of a dark brown, inclining to purple in the inside; fruit medium-sized and tawny-colored, and the pips or protuberances of the fruit being larger and flatter than in the other kinds.

King’s, or shining green. The leaves of a grass-green, the pulp hard and rather stringy, but of good flavor when ripe.

Green, or St. Vincent’s pine. A rare variety, when ripe the fruit is of an olive hue, middle-sized, and pyramidal. It has a nice flavor, shaped like the frustum of a pyramidal; leaves of a brownish tinge, and drooping at the extremities, with strong prickles, thinly scattered. The pips of the fruit are large, often an inch over; and it attains a large size, weighing from three to four pounds. It is of a dark color till it ripens; very sweet, and highly flavored.

Black Jamaica. The fruit is large, and the plants similar in character and habits to the above.

Presidio pine, or new providence. There are two varieties, the white and green; the fruit is larger than that of any of the kinds cultivated in this country; the form resembling a pyramidal; the color at first brownish-green, but when mature a pale-yellow. The flesh yellow and melting, abounding with quick lively juice. Speckley prepared in the garden at Wollaston, in 1794, a fruit that weighed five pounds and a half, and one of the largest ever placed under his care, which fruited in July 1804, the fruit of one plant weighing seven pounds two ounces, and the other nine pounds three ounces, avoirdupois.

This sort, and the two preceding, require generally three years, and sometimes four or five to produce their fruit. What is called the old providence, is a small fruit from one of the Bermuda islands of that name.

Blood red; fruit equal in bulk at both ends. Pips of moderate size; color brick red; flesh white and opaque; leaves of a changeable hue; the flavor of the fruit being inferior to that of most others, this is to be considered merely as a curious variety. (Hort. Trans. iv. 314.)

Silver-striped queen. Leaves beautifully striped with white, yellow, and red; but the plant, though elegant, is a reluctant fruiter.

Variegated-leaves pine. Besides the stripe-leaved queen, there are several sorts with beautifully variegated leaves and fruits, and some with red or brown leaves; but in general they are tardy in fruiting, and more to be considered ornamental than as useful varieties.

New sorts. Fine plants are frequently imported from the West Indian islands, and in this case generally bear their fruits. In general, however, these plants are far inferior, both as to kinds and condition, to those grown, and to be procured from nurserymen in this country. They are generally infested with the bug, and very uncertain in their time of flowering, as well as to their flavor. If these were to be enumerated, the list of pines known in this country would amount to upwards of forty sorts. Specimens of above thirty sorts are grown in the gardens of Gunter, at Earl’s-court. The globe pine—apple, a subvariety of the queen, was sent to England in the year 1773 by John Hodgins, and is now reimported under the name of the Russian globe. (Hort. Trans. v. 265.)

4787. The insects which more especially infest the pine are, the brown turtle bug (Coccus hesperidum, L.) (fig. 505. a to e). The female has at first the appearance of a flat scale (a); afterwards, when depositing its eggs, it becomes fixed and turgid (b); these eggs (c) are hatched under the mother, who soon afterwards dies; the young insects, seen under a magnifier, appear like turtles in miniature (d). Only the males (e), which are few in proportion to the females, have wings; these devour nothing, and having performed the office of impregnation, die.

4788. The white scaley bug (C. hesp. var.) (f to l) bears a considerable resemblance to the above; but the scale (f') is somewhat smaller: the color is white, and the males or flies (l) not so large as those of the brown.

4789. The white mealy crimson-tinged bug (C. hesp. var.) (m and n) differs from the former in being larger and crimson-colored. Speculally considers it as viviparous. This and the former species are much the most pernicious. The various modes of destroying them, and also the other insects which attack the pine, have been already detailed.

4790. The grape-pine is a trailing, deciduous, hardy shrub, with a twisted irregular stem, and long flexible branches, decumbent, like those of the bramble, or supporting themselves when near other trees, by means of tendrils, like the pea. The leaves are large, lobed, entire, or serrated and downy, or smooth; green in summer, but when mature, those of varieties, in which the predominating color is red, constantly change to, or are tinged with some shade of that color; and those of white, or yellow grapes, as constantly change to a yellow, and are never in the least tinged either with purple, red, or scarlet. The breadth of the leaves varies from five to seven or ten inches, and the length of the foot-stalks from four to eight inches. The flowers are produced on the shoots of the same year, which shoots generally proceed from those of the year preceding:
they are in the form of a raceme, of a greenish-white color, and fragrant odor, appearing in the open air in this country in June; and the fruit, which is of the berry kind, attains such maturity as the season and situation admit, by the middle or end of September. The berry or grape is generally globular, but often ovate, oval, oblong, or finger-shaped; the colors green, white, red, yellow, amber, and black, or a variegation of two or more of these colors. The skin is smooth, the pulp and juice of a dulcet, poignant, elevated, generous flavor. Every berry ought to enclose five small heart or pear shaped stones; though, as some generally fail, they have seldom more than three, and some varieties, as they attain a certain age, as the ascalon or sultana raisin, none. The weight of a berry depends not only on its size but on the thickness of its skin, and texture of the flesh, the lightest being the thin-skinned and juicy sorts, as the sweetwater or muscadine; and what are considered large berries of these varieties, will weigh from five to seven pennyweights, and measure from one to two thirds of an inch in girth. A good-sized bunch of the same sorts may weigh from two to six pounds; but bunches have been grown of the Syrian grape, in Syria, weighing forty pounds, and in England weighing from ten to nineteen pounds. A single vine in a large pot, or grown as a dwarf standard in the manner practised in the vineyards in the north of France, ordinarily produces from three to nine bunches; but by superior management in gardens in England, the number of bunches is prodigiously increased, and one plant, that of the red Hamburg sort, in the vineyard of the royal gardens at Hampton Court, has produced 2200 bunches, averaging one pound each, or in all nearly a ton. That at Valentine's, in Essex, has produced 2000 bunches of nearly the same average weight.

4791. The age to which the vine will attain in warm climates is so great as not to be known. It is supposed to equal or even to surpass that of the oak. Pliny speaks of a vine which had existed six hundred years; and Bosc says, there are vines in Burgundy upwards of four hundred years of age. In Italy there are vineyards which have been in a flourishing state for upwards of three centuries; and Miller tells us, that a vineyard a hundred years old is reckoned young. The extent of the branches of the vine, in certain situations and circumstances, is commensurate with its produce and age. In the hedges of Italy and woods of America, they are found outgrowing the highest elm and poplar trees; and in England, one plant trained against a row of houses in Northallerton (lateley dead), covered a space, in 1585, of one hundred and thirty-seven square yards; it was then above one hundred years old. That at Hampton Court, nearly of the same age, occupies above one hundred and sixteen square yards; and that at Valentine's, in Essex, above one hundred and forty-seven square yards. The size to which the trunk or stem sometimes attains in foreign countries, is so great as to have afforded planks fifteen inches broad, furniture, and statues; and even in this country, the Northallerton vine above mentioned, in 1785, measured four feet in circumference near the ground; and one branch of the Hampton Court vine measures one hundred and fourteen feet in length. Vine timber is of great durability. It may be remarked, that vines regularly pruned and dressed, can rarely attain similar magnitudes, nor is it desirable that they should.

4792. The native country of the vine, like most of our acclimated fruits, is generally considered to be Persia; and Dr. Sickler (Geschichte der Obst. Cult. vol. 1.) has given a learned and curious account of its migration to Egypt, Greece, and Sicily. From Sicily it is supposed to have found its way to Italy, Spain, and France; and in the latter country it is believed to have been cultivated in the time of the Antonines, in the second century. It has been found wild in America, and is now considered as a native, or naturalised in the temperate climates of both hemispheres. In the old world, its culture forms a branch of rural economy from the 21st to the 51st degree of north latitude, or from Siciraza in Persia to Coblenz on the Rhine. Some vineyards are to be found even near Dresden and in Moravia; and by means of garden-culture, it is made to produce fruit for the table still farther north, being grown to a considerable degree of perfection in the hot-houses of St. Petersburg and Stockholm.

4793. The introduction of the vine to Britain is supposed by some to have taken place under the first Roman governors, though, from Tacitus, it appears to have been wanting in Agricola's time. There is evidence, however, to prove that vineyards were planted here in the year 280, A. D. (see 312.) and Bede, writing in 731, says, there were vineyards growing in several places. Harte observes, that the religious fraternities of the dark ages spread out from Italy in all directions, carrying with them the knowledge of agriculture and gardening; there is little doubt, Professor Martyr remarks, that orchards and vineyards were common appendages to abbeys and monasteries from their first establishment, at least in the southern parts of the island, to the time of the reformation. From this period they have disappeared, in part, perhaps, from the culture of the vine being little understood by those to whom the lands of religious houses were sold or granted; and in part, because a better article would be introduced from our French provinces in the time of the Henries, and continued to be imported when we lost these.
4791. Vineyards have also been planted in modern times, and wine produced, nearly, if not entirely equal, to that of France. In the Museum Rusticum, it is stated, that at Arundel Castle in Sussex, the Duke of Norfolk had a vineyard, of which there were in his Grace’s cellar, in 1763, above sixty pipes of excellent Burgundy. Bradley informs us, that Warner, a gentleman of Rotherhithe, made good wine from his own vineyards. Switzer mentions several instances, and among others, that of Roeque, of Walham Green, who made wine for thirty years from a vineyard he had planted in a common field-garden. Hanbury and Hales confirm these accounts, and cite others; and Barry, in his History of Wines, gives an account of a very productive vineyard, formed by the Hon. Charles Hamilton, at Painshill, in Miller’s time, which succeeded for many years, and produced excellent champagne. It is not yet twenty years since this vineyard was neglected or destroyed. There can be no hesitation, therefore, in agreeing with these authors, and with Miller, Martyn, and Speechley, that vineyards would succeed in various parts of England, and produce wine equal to much of that imported from France. But, in a national point of view, we may conclude with equal safety, that the culture of the vine, as a branch of rural economy, would not be a profitable concern here, on the broad general principle, that it cannot be long worth while to grow any thing at home which we can get cheaper from abroad. The high duties on imported wines may seem to bear against this opinion; but this is merely a temporary cause; for, in the progress of international commerce, governments gradually discover the advantage of leaving trade comparatively free; and in proportion as this becomes the case, each country will feel its advantage in pursuing those branches of industry in which nature or habit has rendered it pre-eminent. It may, however, afford much rational satisfaction for individuals, in favorable situations, to form vineyards, and drink their own wine.

4795. Grapes for the table appear to have been in demand as early as the beginning of the 16th century; for Tusser includes “grapes white and red,” in his list of fruits, published about the year 1560; but as far as appears from horticultural literature, the vine had only been grown as dwarf standards, or trained against walls or buildings, till the beginning of the 18th century. Stoves for preserving curious exotics had been introduced soon after the middle of the 17th century; but we find no mention of the application of artificial heat to the vine, till 1718, when Lawrence informs us, in his Fruit-Gardener, published that year, “that the Duke of Rutland, at Belvoir Castle, has done so much justice to the vine as to have fires constantly burning behind his slope walls, from Lady-day to Michaelmas; whereby he is rewarded by the largest grapes, and even the best Frontignacs, in July.” These sloped walls, we are informed, were afterwards covered with glass. Switzer (Pract. Fruit. G. 2 edit. 1763.) appears to be the first author who gives a regular plan of a vineyard, with directions for forcing the grape. He advises making fires as early as the middle of December, so as to make the vines push by the middle of January. Since his time, the art of forcing has made such rapid progress that no kitchen-garden worth notice is now without a vineyard: the fruit is produced in some vineeries during every month of the year; and in the London markets is to be had in the highest degree of perfection from March to January. Vines are at the same time still grown on walls unaided by fire-heat, and in favorable seasons, the more hardly early sorts attain a tolerable degree of maturity. In the nursery-gardens of Joseph Kirke at Brompton, a wall upwards of two hundred and twenty yards long, and ten feet high, is covered with plants of the white muscadine, which have produced regular crops for many years. On the border to this wall are standard vines of the same sort, trained to stakes about four feet high, which also bear in proportion, though the fruit does not ripen quite so early, nor attain an equal degree of flavor with that on the wall. In propitious seasons these grapes attain a tolerable degree of flavor; but even then they are of little value, compared to those grown in vineeries and hot-houses.

4796. Use. The uses of the grape in Britain are well known; in the dessert it ranks next the pine, and is by some preferred to it. The berries, when green or not likely to ripen, may be used in tarts or pies; and the leaves form an elegant garnish to other table-fruits. Wine is sometimes made in England, by expressing and fermenting the juice, either alone or with that of other fruits; and it has even been made from decoctions of the leaves of some sorts. In warmer climates, the grape is not only used in the dessert, but eaten with bread, either newly gathered or dried as raisins; and in these countries, from the fermented juice, a wine or liquor is made superior to all others for stimulating the stomach, and exhilarating the spirits of man. Some of the most important consequences in the mythological history of man, are referred to its last-mentioned qualities. (See the Histories of Lot, Noah, and Bacchus.) The medical products of the vine are verjuice, formerly used as the juice of lemons: tartar, a gentle cathartic: vinegar, used as a condiment; for extracting the virtues of other medicines; and for counteracting the effects of vegetable poisons. Even wine itself is given as a medicine, in typhus fevers; in nervous disorders; in putrid sore throats; and even in the plague. “In almost all cases of languor, and great prostration of strength,” Martyn observes,
"wine is a more grateful and efficacious cordial than can be furnished from the whole class of aromatics."

4797. Varieties. These are exceedingly numerous; partly from the antiquity of the vine, it having, as Professor Martyr remarks, been cultivated from the time of Noah; partly from the influence of soils and climates in changing the qualities of grapes, there being hardly two vineyards in France or Italy where the sorts, though originally on the same, remain long precisely alike; but chiefly, as far as respects this country at least, from the facility with which new sorts are procured from seed. Tusser, in 1560, mentions only "white and red" grapes. Parkinson, who was more of a horticulturist, gives, in 1627, a list of twenty-three sorts, including the white muscadine, "very great, sweet, and firm; some of the bunches have weighed six pounds, and some of the berries half an ounce." Ray, in 1688, enumerates twelve sorts as then most in request. Rea, in 1702, gives most of those in Ray's list, and adds five more sorts, recommending the red, white, and the d'Arbois, or royal muscadine, the Frontignacs, and the blood-red, as the fittest sorts for England. The best vines, he says, were then on the walls of the physic-garden at Oxford.

4798. Suizewy, in 1717, says, "It is to Lord Capel and Sir William Temple that we are owing that collection of good grapes not so plenty in England; the latter," he says, "brought over the Chasselas, parleyse, and Frontignac; and also the Amboyna, Burgundy, black muscat, and grizzly Frontignac; all highly approved, and distributed amongst the nurserymen, as well as the nobility and gentry. The best grapes which he tells us, "were grown at Wickenden, Isaworth, and Blechmond." Speedily, from 1760 to 1791, excelled in the culture of the vine at Welbeck.

4799. The most valuable modern additions to the varieties of grapes in this country have been procured by sowing the seeds of sorts ripened in that country. This excellent grape, the red Hamburgh, was raised from vines in Hamburgh, Prussia, by Mr. Hotham, who by naturalizing the same, has produced the variety of the black cluster, which bears his name. Speckly produced various new sorts, which have now place in the catalogues of nurserymen. Williams of Pitmaston, Bradrick of Thames Ditton, and, above all, the President of the Horticultural Society, have raised several excellent varieties of the muscat and blood-red sorts. The greatest number of new sorts, as go abroad, has also contributed to the number of grapes. New sorts have been sent from Spain, Italy, and the East Indies, and many from France; so that the lists of some British nurserymen exceed two hundred varieties. From France, in particular, the constitution of the country, the character of the soil, and the climate, when minister of the interior, ordered a specimen of every known variety of the grape to be collected from the different departments where the vine is grown, and planted in the nursery of the Luxemburg garden, with a view to ascertain their respective merits. Though this assortament was never completed, the lists of the hundred and one hundred new sorts, are still in use.

4800. A classification of the numerous varieties of the vine has not yet been made, either in France or England. Bose, the inspector of government-nurseries in France, was employed to compare and class those collected at the Luxembourg; but in 1805 he had only succeeded in describing and figuring fifty distinct sorts of grapes. Of his classification was, the color, form, and size of the fruit; the surface, margin, texture, color, and position of the leaves; and the redness, greenness, or variation of the foot-stalks. From these eleven characteristics combined, he forms 150 classes, in which, he says, may be placed all the possible varieties of grapes. Bose, aware of the great variety of considerations of another order, which augment the number of characteristical, such as grapes which are in other respects alike, yet differ in their time of ripening, in the time they will hang without alteration on the quantity produced on a plant, quality of the pulp, &c., acknowledges, that, after four years' labor, he could only obtain an approximate collection. The Luxembourg collection, published by Harvey in 1802, the arrangement is, 1. vines with black oval fruits, 37 sorts; 2. black round fruits, 99 sorts; 3. white oval, 44 sorts; 4. white round fruits, 75 sorts; 5. grey or violet oval fruits, 5 sorts; and 6. grey or violet round fruits, 10 sorts: in all, 207 sorts. The most elaborate descriptions of the varieties of the vine which Bose has published were contained in a paper in the Philosophical Transactions, "De generis vinorum varietates," by D. Simon Roxas Clemente, librarian to the botanic garden at Madrid. This author finds his varieties on the character of the stem, shoots, leaves, flowers, bunches, and the color of the fruits; telling them in two gross things, by the species natural, in which section is arranged in tribes or clusters of sub-varieties, bearing one common name, and distinguished by a common character in some part of the fundamental characteristics above named, and into isolated varieties, which he describes singly. He enumerates thirty-six authors who have written on the vine, since Columbus, by whose names he has distinguished many of his tribes; the others by their local appellations. The table of grape-vines here given is, we acknowledge, very imperfect, but it contains all the information which we have been able to embody from the best authors, and especially from Speedy and Forsyth. More than triple the names it contains might have been inserted; but, without being accompanied with descriptive particulars, they could be of no real use.

4801. Estimate of sorts. As it is generally a puzzling consideration for inexperienced persons to make a selection from the ample descriptive catalogues of authors and long lists of names kept by nurserymen, it shall here be of common use to compare the several sorts of grapes which will rise, the foliage in autumn will be alternately tinged with red and yellow; and, supposing the muscadine to be placed next at the end at which the fine enter, they will ripen nearly a month earlier than any of the others; the Muscats, Frontignac, and Sillery, contain the berries being at the end, the Frontignacs, will have a sufficient heat to ripen them; and the three last sorts, the black, more tardily will come in succession.

To plant a vineyard for a late ripening kind. Take the black Darnacissus, black Frontignac, black Muscat, golden Muscat, red Syrahes, Syrahes of the Isle of France, and white raling, black and white St. Peter's, black prince, &c.

To prepare a house in which vines are grown: one plant under each raffer. Take the white and red muscat, black muscadine, red or black Hamburgh, red Syrahes, red and white raling, black and white Frontignac, white and red Burgundy, &c.

Vines to plant against a common garden-wall of south exposure, or against the walls of a house. The July black, white muscadine, white and black swettier, small and large black and white muscadine, &c.

To plant a vineyard for early fruiting. Take the white, black, small-leaved, black muscadine, red and black muscadine, a white and red muscatel, a white and a black muscadine, a white raling-grape, a white and red muscatel, a white muscadine, black muscadine, red swettier, a white and red swettier, &c.

There are here 20 grapes of 14 distinct flavors; an equal number of both colors; large showy bunches and berries, as those of the Nice; and small high-flavored ones, as those of the Frontignacs; the whole placed in the order in which they will ripen. The foliage in autumn will be alternately tinged with red and yellow; and, supposing the muscadine to be placed next at the end at which the fine enter, they will ripen nearly a month earlier than any of the others: the Muscats, Frontignac, and Sillery, bears berries being at the end, the Frontignacs, will have a sufficient heat to ripen them; and the three last sorts, the black, more tardily will come in succession.

To plant a vineyard for a late ripening kind. Take the black Darnacissus, black Frontignac, black Muscat, golden Muscat, red Syrahes, Syrahes of the Isle of France, and white raling, black and white St. Peter's, black prince, &c.

To prepare a house in which vines are grown: one plant under each raffer. Take the white and red muscat, black muscadine, red or black Hamburgh, red Syrahes, red and white raling, black and white Frontignac, white and red Burgundy, &c.
Abbreviations. — h. hot-house; v. vineyard; w. common wall.

| 55. Red Chasselas | Red Muscadine, coral | Originated by Miller about 1738 | — | For. 51. | — | Small and round | Highly musked, visous, and rich | Late | — | — | — | A very good grape. |
| 56. Variegated Chasselas | Orig. from the Aleppo Muscadine by Knight, about 1811 | — | — | For. 52. | — | Very large | Highly musked, visous, and rich | Late | — | — | — | A very good grape. |
| 57. Chasselas Panache | Striped Muscadine | — | — | Hort. Tr. i. 238. | — | — | — | — | Late | — | — | — | A very good grape. |

*Note: The table provides a detailed description of various grape varieties, including their origin, physical characteristics, and general reputation.*
4803. Propagation. The vine is propagated from seed, layers, cuttings, grafting, and inoculation. By seed, for the sake of obtaining new varieties; by layers, to get strong showy plants the first year; by cuttings, for economy in management, and to get plants with tops proportioned to their roots; and by grafting and inoculation, for various useful and curious purposes.

4804. By seed. The first thing to select the seeds. If the object be to propagate an esteemed variety from which cuttings cannot be obtained, or to procure a subvariety of any esteemed sort, then select the largest and best-ripened berries from the largest and best-formed bunches, out of which to take the seeds. But if the object be to procure an entirely new variety, then the first preparatory steps must be taken when the vines are in flower, either by bringing them together as was practised by Loudon, or by cross-pollination, as was practised by Speedy; or by cutting out, with small scissors, the stamens from the flowers to be impregnated, before their anthers had burst, and introducing the pollen of the variety with which it is to be crossed or impregnated, by dusting the stigma with the pollen of the other plant. The practice of Speedy was most certain, because if the blossom destined to bear seeds be fecundated or set, it must evidently have been set through the influence of the stronger pollen; and the most effectual, because the stronger pollen operating alone must have more influence on the progeny than when operating in conjunction with that of the blossom to be crossed.

4805. As some guide for the selection of sorts to breed from, (to borrow the phraseology of a sister art,) we may state, that the legitimate object which ought to be had in view, should not merely be to obtain a new variety, but one, either superior in the size, both of the bunch and berry, superior in flavor and delicacy of skin and flesh, superior in point of hardness of bearing, or in resisting some colliding, in connection with each of these particulars, the form of the bunch, and the length of the foot-stalk of the fruit, and even the size of the leaves and the length of their foot-stalks, are also objects deserving attention; cleanliness, neatness, which always contributes to short-foot-stalks. "All sorts of Frontignac grapes," Speedy observes, "are proper to add an excellency of flavor to other kinds: but there is a superior richness in the black, blue, and red Frontignacs; and they do not partake so much of the strong muscat flavor as the white and grizzly do. But it must be considered, that the black Frontignac, is close upon the bunch, and therefore, is only proper to be coupled with the loose-growing kinds, that have long foot-stalks. The white muscat of Alexandria produces large loose-growing bunches, and the berries being very large and well flavored, it must be a proper kind to be coupled with sorts of this character. There is a peculiar delicacy in the flesh of the white sweet-water; it is also a remarkably thin skinned grape, and being large, and the binomial entrance of the berries is very much larger than in Frontignac, and are small and less delicate. Were the red Frontignac and white sweet-water wedded together, their union would probably produce a very valuable sort, as there would be a good chance of its being both large and delicate, and having the flavor of both the sweet-water and French grape; for producing more astonishingly large bunches, and, therefore, I would not advise the joining this coarse crass to any other excellent variety, by allowing, as in all likeliness, the offspring would only produce bunches much less ponderous. But the white muscat of Alexandria, having larger berries and longer foot-stalks, there would be a probability of producing grapes of this kind, and for the present, and as we have no other example of Frontignac, it is as the only thing to make the Frontignac grapes fit and delicious. The following kinds also admit of a junction with great propriety, viz. "the black Damascus and grizzly Frontignac; the flame-colored Tokay and red Frontignac; the white muscat of Alexandria and white sweet-water; the black Frontignac and white muscatbine; the St. Peter's grape and white muscat, and muscatine;" for other examples might be cited, but those Speedy considers "sufficient to indicate the persons of taste and curiosity to pursue an amusement that one may venture to pronounce will contribute both to their advantage and pleasure." He augurs, that "the best sorts of grapes hitherto known will at some future time be esteemed only as secondary kinds. (Treatise on the Vine, p. 44.) Neill observes, that "the real pecurial, so new engaged in the raising of cutting, in all probable some excellence, and hardy kinds will soon be produced; so that another generation may once more see vineyards common in this country. (Ed. En. art. Hort.)" Grapes, for seed, should be permitted to remain on the plants, till the berries are quite ripe, and perfectly matured; as the seed is formed in the pulp, and preserved till February or the beginning of March. They should then be sown in pots filled with light fresh mould, and plunged in a moderately warm hot-bed; they will come up in four or six weeks, and when the plants are six inches high, they should be transplanted singly, in the open ground, six inches apart, in rows of larger distance, and with due regard to the abundance of light and air, and carefully avoid injuring any of the leaves. Cut down the plants every autumn to two good buds, and suffer only one of these to extend itself in the following spring. Shift into larger pots as occasion requires, till they have produced fruit. This, under good management, will take place in five years, when all approved sorts should be selected and the rest destroyed, or used as stocks on which to graft or inarch good sorts.

4806. Forsyth, and some other authors, advise planting seedling vines the second year of their growth, against a wall in the open air, and there letting them remain till they produce fruit. Where there is abundance of walling to spare, and no great haste requisite for proving the fruit, this is a very good mode, as the fruit in such a case is certain of growing larger, and therefore affording a better opportunity of judging of its merits, as to size of bunch and berry. Keeping the plants in large pots, on the other hand, though the bunches and berries may not grow quite so large, yet as both the wood and fruit may be ripened under glass, it is a more eligible mode; the plants will produce fruit sooner, and that fruit will be of better flavor.

4807. Speedy says, "it would not be prudent to furnish a wall with any part of a hot-house, and seedling vines in their unripened state, or before they have produced fruit; for although the prospect of obtaining good kinds from seed saved, in a hot-house, be more promising and certain than that of getting them from seed of grapes in vine countries, (because there, when the vines flower, the very air is impregnated with the pollinizing stamens,) in this climate, where the heat is not always such as to render it advisable to introduce the plants in a vineyard; for though it may not have the sweetness, flavor, bulk, or precocity desired in an eating grape, it may be of that insipid large-berried kind, which is fit only for making the most inferior wines. In most vine countries, a small black berry will make a more valuable and lasting vine, and an acre of it will supply the demand of ten or fifteen acres to all others." (Treat. on the Vine, 8vo. edit. p. 60.) It may be observed, that though vine-plants raised from the seeds of black or red grapes will generally produce red or black berries, yet they will occasionally produce white berries, sometimes, and the white berries are sometimes, of such a delicate color as to be highly esteemed. Thus plants, from stones of the peach, will sometimes produce nectarines, and though a nectarine-stone will, in general, produce a tree of the same kind, as Collinson experienced (Smith's Correspond. of Linn. 71.), yet it will sometimes also, as the French gardeners declare, produce trees bearing peaches.

4808. By layers. The advantages of layers are generally stated to be that of procuring large showy plants that come immediately into bearing, and have been (927.)
a successful instance of this practice from layers made in a vinery; but when taken from stools in the open air, it happens almost always that the roots of the layer are not ripened; the consequence of which is, that their extremities rot off, and the following year the plants make hardly any shoots. Layering without, or but with a trifling incision, as is too frequently done in the hurry of nursery business, greatly contributes to this effect, by obliging the shoot to derive all its nourishment from the parent plant or stool, to which, in autumn, the descending sap is returned. Whereas, when a deep incision is made, or a ring of bark taken off in Williams's manner (2168.), less sap ascends, the shoot is not so long, it ripens sooner, and the descending sap reposes in, and ripens the roots. It is not easy to conceive in what way plants so raised can be inferior to those raised from cuttings of one or of several eyes; though it appears to be the general opinion that they are not so long-lived as plants raised from one eye. "Vine-plants raised by layers," Speechly observes, "are much inferior to plants raised by cuttings, both in point of future vigor and durability." Hitt wonders how any one can prefer cuttings to layers, since the former are always one year beyond the latter.

4809. By cuttings. The advantages of propagating by cuttings are economy in labor, economy in the wood or shoots to be propagated from, and tops or shoots proportioned to the roots. There are three kinds of cuttings used in propagating vines:—

4810. Long cuttings. The first are from a foot to eighteen inches long, consisting of new or young wood, with a joint or two of that of the preceding year. This is the sort recommended by Miller; and adopted in France and formerly also in this country in planting walls or cuttings in the vineries. They are inserted so as to leave only two eyes above ground; the earth is firmly pressed round the lower part, to which the old wood is attached; they are mulched, and water is supplied regularly in dry weather. Cutting of this sort, so treated, strike freely, as Speechly observes, either with or without bottom heat. They may be seen the following year from the base of the shoots. The leaves and grapes the first year. Justice says he prefers stock ing a vinery from such cuttings to using rooted plants.

4811. Short cuttings. The second mode is that of forming the cuttings with only one eye on young or one-year-old wood, and a few inches of that of the preceding year attached. "Each cutting should have two inches of the old wood, with one eye of the new. The bottom part should be cut perfectly smooth; plant in pots, one cutting in each pot, which, as to size, should be a forty-eight. When the plants begin to grow, and the pots full of roots, it will be necessary to shift them from the forty-eights to the thirty-twos." (Speechly.)

4812. Single eyes. By the third mode, the cuttings have only a single eye on young or one-year-old wood. This mode was first adopted by the Rev. M. Mitchell, and by him communicated to Speechly, along with the former; and the reasoning that follows is from his mind. "It is the opinion of the late Earl Connyngham, that the cuttings are generally preferable to layers, and that plants of any sort raised from small cuttings, commonly make the best plants. The new plant is injured in proportion as it partakes too abundantly of its original or mother plant. Hence, the less the bulk of the matter that forms the new plant the better; for plants raised from seed have the smallest beginning of any, and are preferable both to layers and cuttings." (Tr. on Vine, 52.) Perhaps, the chief advantage of propagating by eyes in preference to short or long cuttings or layers, is, that the sets are more manageable, and can be more readily potted and placed in pots or frames to receive bottom heat; on which, applied early in spring and continued through summer, accompanied by proper shiftings and waterings, much more than on the form of the cuttings, depend abundance of roots and fitness for bearing the second year. We have seen single eyes raised in nurseries, produce strong shoots from ten to twenty feet the first year, and others, in cold frames or pits, well large as much as twenty feet, to the spring, that to a shoot in the cutting three feet. Ripen wood is to be chosen for propagating by eyes; and though some are of opinion that cuttings from the lower part of the vine are preferable to those that grow higher and at a distance taken from the root, yet Speechly says, he never could find any difference, provided the wood was equally well ripened. This is, he considered, that it must either always be generally be found at the most distant parts from the root, as vines generally generate first at the extremities of the shoots, or that at these extremities will be found both the strongest, earliest, and best-ripened wood, and largest and most abundant bunches of fruit. Very strong shoots abound too much with pith to make good cuttings, the requisites to which are as follow:—"1. The eye or bud should be large, prominent and bold. 2. The shoots should be moderately strong, round, and short-jointed. 3. The texture of the wood should be close, solid, and compact; and the best criterion of its maturity is, its solidity, and having been little pith." (Tr. on Vine, 57.)

4813. By grafting. The advantages of this mode of propagation may not at first sight appear, but they are, Speechly observes, "many and important." First, when a wall, or vinery, is planted with inferior kinds of vines, the usual method of stubbing them up and supplying their places with better sorts, is attended with much expense and loss of time; as several years must elapse before the wall can be completely finished with new vines; but, by grafting, the nature of the vines may be changed without expense or loss of time; for I constantly have good grapes from the same year's graft; and in a hot-house the grafts, if permitted, will frequently shoot thirty or forty feet the first summer. Secondly, in small vineries, or vine-frames, where it would be inconvenient to have any considerable variety of sorts from roots, they may be procured by grafting different kinds upon one and the same plant. A Syrian vine now (1759) growing in the hot-house at Welbeck, produces sixteen different sorts of grapes. But the most important advantage, Speechly considers to be, "the improving the various kinds
of grapes, and particularly the small kinds, which generally make weak wood. By grafting the weak and delicate growing vines, as the blue Frontignac, upon robust and vigorous stocks, as the Syrian, it will produce well-sized handsome bunches, almost as large as those of the Hamburgh." The Syrian vine, raised from seed, is greatly preferable to all others for stocks. If the seed degenerate to a kind of wildness, so much the greater will be the vigor of the plants, and the higher the flavor of the sorts grafted on them. At the pruning season select cuttings for grafts from the best bearing branches, in general preferring the bottom part of last year's shoot; preserve them, by inserting them three parts of their length in pots, till wanted. The season for grafting in stoves is the beginning of January; in the open air, the middle of March. On small stocks not more than one inch in diameter, cleft-grafting will be found the most proper; but, upon larger stocks, whip-grafting is to be preferred. As vine-grafts do not take so freely as those of most other fruits, the operation must be performed with the greatest care. But the most eligible mode of grafting vines is that by approach, in which case either the stock or scion must be growing in a pot. Strong plants, two years potted, are to be preferred for the open air; but, for a vineyard or hot-house, plants from the nursery may be potted, or shifted, if already in pots, and inarched the same season. In whip or cleft grafting, the clay may be taken off when the scion has made shoots five or six inches long; but here both clay and bandage should remain two or three months after the graft has formed a union, lest the grafted part spring from the stock.

4814. Knight finds grafting most successful when the lower part of the scion consists of two-year-old wood, and when the graft is well covered with clay kept moist, or if the branch be on a horizontal trellis with the scion placed under the scion graft, and the point of junction kept well covered with earth occasionally watered. (Hort. Trans. iv. 105.)

4815. Braddick has made several experiments on grafting vines: he found the scion generally sodden by the bleeding of the stalk; but, at last, he contrived by a very close bandage round the graft to force the sap from the scion to the scion. For the vining, in his experiments, he says, "I feel confident in stating, that healthy vines may be successfully grafted with young wood of the preceding year's growth, from the time that the shoots of the stocks which the grafts are to be put upon, have made four or five eyes, until midsummer, with every prospect of the graft's surviving, and at least during about four months suffering by bleeding. They may likewise be grafted with shoots of the same summer's growth, worked into the rind of the young wood, from the time that the bunches of grapes become visible on the stocks till July, out of doors; or till a month later, under glass. The operation must not be performed later than the periods here specified, because time is necessary for the young shoots of the graft to become hard and ripe before winter." (Hort. Trans. v. 204.)

4816. Culture. For the culture of the vine in the forcing department, see Chap. VII. Sec. II. What follows concerns chiefly the management of vines in the open air.

4817. Soil. The vine will thrive in any soil that has a dry bottom; in such as are rich and deep, it will grow luxuriously and produce abundance of large fruit; in shallow, dry, chalky, gravelly, or schistous soils, it will produce less fruit, but of better flavor. The greater part of the vineyards of France, Bosc observes (Cours complet d'Agriculture, &c. art. Vigne), are on a soil argil-calcaireous: sometimes primitive, as those near Dijon; and sometimes secondary, as those at Bourdeaux. Argillaceous gravel is the next in frequency, as near Nimes and Montpellier, and which produces the Vins des Grapes of Bourdeaux. Both good and bad wines are produced from the débris of granites; among the former are the cibes roties and the cibes des Sommières of Ardeche, and the cibes of St. Augustin, and many other wines from schistous rocks. Wines which are made from vines planted in chalky soils, are weak, colorless, and do not keep well, as those of Champagne. Wines grown on the ashes discharged from volcanoes are excellent, as those of Vesuvius and Etna. Soils surcharged with oxide of iron, red or yellow, are not less proper for making the mild wines of the chief vineyards of France, than the earthy clays; and the petroleum chalk, which contains a great deal of bitumen, is the most productive; the fruit, if it sets, does not ripen; the shoots not ripening well are more easily affected by frosts; and the wine, if any can be made, is weak and flavorless. Such a soil, even when in a warm climate, is particularly not very productive in the vine, and is observed to be stubborn, as in South Carolina, by Michaux. There vines brought from France produced for six months in the year, buds, leaves, and shoots; flowers, the greater part of which proved abortive, and green and ripe berries. This circumstance, he considers, will prevent the successful culture of the vine in that part of America.

4818. Switzer observes, that the soil for the vine should be light, having a bottom of chalk or gravel under a surface of about two feet deep and free from springs; it cannot be too hot nor too dry, provided it be not in its own nature so very barren that nothing will grow upon it. If given to brambles, it is a certain sign of fitness, as no plant whatever is so co-natural to the vine as this shrub. In chalky-bottomed lands, which are not very much low, where it is not very hard to be drained, and where these are most adequate, we dare even challenge Paris itself to excel us. (Pr. Fruit Gard. 149.)

4819. Hitt, having observed a vine at Belvoir Castle growing out of the stony foundation of a wall, without any other root-plant, and producing what were afterwards wine, and early ripe, than any other in the open ground in these gardens, advises the mixture of lime-rubbish, brick-hats, &c. for a foot deep in the bottom of wall-borders destined for the vine. (Tr. on Fr. Tr. 12.)

4820. Lawrence says, "he cannot easily be brought to think that any soil or situation can be too dry for the vine; the roots having, near the wall, the advantage of growing in the joints of an old castle-wall, near twenty feet high from the ground, and which produced admirable crops of grapes when well managed. (Fruit Gard.)"

4821. Specky says, "the soil in which I have known the vine to prosper in the most superlative degree without artificial aid, is a kind of rich clayey loam, intermixed with beds of materials like jointed slate or stone, so soft in its nature as almost to be capable of being crumbled between the fingers." Strong and deep lands most suitable for tillage are the least so for vines, and hence the introduction of vineyards would be more advantageous. (Tr. on. 146.)

4822. Manures. Dung, Specky observes, should not be permitted to approach the roots of vines till it be perfectly reduced to a kind of black mould. Soot, wood-ashes, pigeons' and hens' dung, he considers too hot for the root of the vine; pond-mud and moor-earth too cold. Stale-yard-dung is too hot, and, if newly introduced before its heat is thoroughly abated, some sorts of lime are bad, but others might be advantageous, if introduced into vine-compost. *Vines are greatly injured in their roots by the common practice of laying-rubbish in the bottom floor of the preparation in the ground. Blood, the offal of animals or shambles' manure, horn-shavings, old rags, hair, shavings of leather, bone-dust, dung of deer and sheep, and human ordure,* are admissible when duly mellowed by time, a win-
ter's frost, and repeatedly turning over. The dust and dirt of roads, Speecky greatly esteem as a manure for vines; its fertile nature he attributes, "in part, to the dung, urine, and other rich materials of which it is composed." The grower who has not a chance to make this kind of humus can, of course, get it hy pulverisation." (Tr. on the Vine, p. 57.) Cow-dung is generally preferred for the vine in France; but the vine-growers take every sort they can get: the more careful, however, form composts of earths, leaves, wood ash, and other materials, which, when they turn over a year at least before using. In some places, lithy dung is buried in trenches between the rows of vines, or it is spread on the surface, and regularly dug in. Green crops are sown and dug in some places. (Cours. Complet, &c. art. Vigne.) Forsyth considers the best manure for vines to be a mixture of vegetable mould, rotten manure, and fresh loam, which should be thrown into a heap and frequently turned a year or two before it is used. The vine is allowed by all gardeners to be a gross feeder; the fertility of both the Hampton Court and Valentine's vines are attributed to their roots having found their way, the former into a large common sewer, and the latter into a pond of stagnated muddy water. (Hort. Trans. in 1759.) Some vines in the Hudsons, &c. hot-bedded abundance of blossoms the second season from the eye, and the young odor of the vines the third year is now (June 1. 1820.) throwing out late in great numbers of flowers; so that these the vine year are producing two crops, one of which is now ripe and the other in bloom. The cause of this extraordinary fertility appears to be the same as that which causes the two crops of equal parts of garden-earth and blood mixed together, and repeatedly turned over one year before using.

4823. Vine-walls. A south wall is always to be preferred for vines; though, in some years, the harder sorts may attain a tolerable degree of perfection on a wall considerably inclined to the east or west. Vines, Speecky observes, do well on low walls six feet high; and it has been found that the plants grow stronger, and afford larger grapes when they do not exceed four or five feet in height; they enjoy in this way both the reflected heat of the wall and of the earth. Flued walls have been tried for vines in some parts of the north of England; but Speecky, and English gardeners in general, do not approve of the practice. In Scotland, though flued walls are more common and better understood, yet vines are seldom planted in the open air. For standards or plantations in the way of vineyards, Switzer recommends, "that side or declivity of a hill lying to the south or south-east, which, if favored with other hills, somewhat higher, clothed with wood on the north, north-east, and north-west, will break the severity of those adjoining quarters." Speechly concurs in this opinion, adding, that the hills in the counties bordering on the English channel, have in general declivities tending to the south, and are, therefore, highly favorable for vineyards. Steeps of poor gravelly and rocky soils, in warm situations, would produce more under vines than under any other crop.

4824. Sorts for the open air. Some of these have been already enumerated. (4801.) An addition may be made to this list by saying: The table grape is a variety.

4825. Planting. Where a wall is to be entirely covered with vines, three plants of a sort may be planted at the distance of three, or if a large-leaved kind, of four feet from each other; the two outer plants to be considered as temporary, to fill the wall and produce a supply of fruit, and the centre plant to be considered as the permanent, or the one that will the whole wall will be occupied by. The temporary ones should be trained chiefly on the upper part of the wall, and the permanent ones below; and in four or five years the latter will be in a state to cover the wall, when the former may be rooted out. When vines are only planted against a wall, and other fruit-trees on plantations within a narrow upright space, than one plant to each is sufficient. Some however, as Forsyth, plant two against a pier, one on each side; but this is more to obtain a variety of sorts than to fill the space.

4826. In pruning and training in the open air, any of the modes described as applicable to forced vines (2965) may be adopted. As they break more regularly in the open air than when forced, the spur-method (fig. 455.) and the fruit-tree method (fig. 456.) seem to deserve the preference.

4827. Williams, of Fitmasteron, (Hort. Trans. ili. 253) describes a mode of training so as to fill up the vacancies of other fruit-trees, which seems well deserving attention. "A vine," he says, "might be trained horizontally under the coping of a wall to a great distance, and by inverting the bearing shoots, the spaces between the other fruit-trees and the top of the wall could easily be filled up, and if different vines were inarched to the horizontal branch, the south wall of a large garden might be furnished with a variety of sorts from the stem and root of a single plant, the roots of which would not interfere with the border in which the other fruit-trees were growing. I have an experiment of this kind now in progress in my garden. Within a few years past I have gradually trained bearing branches of a small black cluster-grape to the distance of nearly fifty feet from the root, and I find the bunches every year grow larger, and ripen earlier as the shoots continue to advance. According to Knight's theory of the circulation of the sap, the ascending sap must necessarily become enriched by the nutritious particles it meets with in its progress, and the more it circulates the more nourishment it can distribute. The long, narrow, short-jointed and full of blossom-buds, and the fruit there situated attains its greatest perfection. Hence we find pine and fir trees loaded with the finest cones on the top boughs, the largest acorns grow on the terminal branches of the oak, and the finest mast on the high boughs of the beech and chestnut; so like-wise the best and most proportioned fruits, the most bountiful and well made, are found under the trees. But if the sap and its nourishment be obstructed in its course, or if there be certain limits beyond which the sap would be so loaded with nutriment that it could not freely circulate.

4828. Training the shoots of vines along the ground like those of melons and cucumbers has been proposed by Vispre (Disert. on the Growth of Wine in Eng. Bath, 1786,) and was practised by him on a small scale at Chelsea, where, "the grapes were considerably larger than those of the same kind growing on a south wall, and well ripened." Bacon had before suggested this mode, from a report that "in some places the gardeners grow the grapes upon the ground, and the grapes grow so large, and the fruit is very large, &c." It appears from Vispre, that the Rev. M. Le Brocq had taken out a patent for training fruit-trees in this manner. Speechly says, "Fruit-trees of various sorts have been so trained at Welbeck for fourteen years;" and we have seen the practice adopted in the Earl of Selkirk's garden at St. Mary's Ile, near Brougham, above the lake, in 1819. Fig. 492.

4829. Growing the vine on espaliers. This may be done, following the same directions in all respects as for walls; but it is evident that, under such treatment, the fruit will not come to the same degree of maturity as when enjoying the shelter and reflection of a compact screen. When trained on espaliers the vine is made from green grapes, as it is now frequently done, the practice may be preferable to growing the vine as dwarf standards.

4830. The growing the vine as standards. This practice may be adopted either in the borders of gardens or in extensive plantations as vineyards, and the plants may be trained either like red currants or raspberries. In the former case no stakes are used; but about a foot from the ground, three or more shoots.
eighteen inches or two feet in length, diverge from the stem, and supply young wood annually for bearing. The summer pruning consists in removing shoots which have no fruit, or are not wanting for the succeeding season; in topping fruit-bearing shoots, and also those for the succeeding seasons, which are inconveniently long and straggling. For as by this mode the shoots destined to bear are cut into three or four eyes at the winter season, no inconvenience arises from their throwing out laterals near the extremities, which stopping will generally cause them to do. This mode is adopted in vineyards on dry rocky situations, where the shoots do not run in the wood racks, the single stem at bottom is not allowed to exceed six or eight inches in height, and from this two or three shoots are trained or tied to a single stake of three or four feet in length. These shoots bear each two or three bunches on the top, as it is the fashion, and they are annually succeeded by others which spring from their base; that is, from the crown or top of the dwarf main stem. This is the mode practised in the north of France and in Germany; in the south of France and in Italy, the base or main stem is often higher, and furnished with side shoots, in order to afford a greater supply of bearing wood, which is tied to eminent greater height. Summer pruning in this case is nearly the same as in the last. In the winter pruning, the wood that has borne is cut out, and the new wood shortened in cold situations to three or four eyes, and in warmer places to six or eight eyes.

4831. Formation of vineyards. A vineyard is a collection of standard vines, planted in rows of a greater or less width, according to the height and mode of training proposed to be adopted; and according as the soil may be rich and deep, or poor and thin, or its surface flat or inclined. A square yard of surface to each plant, when they are kept low, may be considered as a desirable medium.

4833. Where plantations of vines are made on the sides of very steep hills, it is sometimes customary to form the terraces, as it is usual to name the beds rising up the sides or terraces depends on the regular or irregular declivity of the hill. When the declivity is regular and the hill steep, each terrace is narrow and supported by a wall, against which the vines are planted and trained as on low garden-walls or espaliers; but, in general, the irregularity of the declivity and surfaces of hills, caused partly by the regularity of the declivity and height of the terraces, and in these cases the vines are planted as standards, according to the room afforded by the platforms of the terraces. The walls which support these platforms in vine-countries, are generally too rude to admit of training against them, and therefore one of the standard modes above described is almost always adopted.

4835. Preparing the ground for a vineyard. On the continent the vineyards reckoned best for making wine are by no means the most agreeable to eat; and there is always a clear distinction made between fruits to eat, and fruits for the press, by the nurserymen, who, in general, have only plants of the former sort for sale. The names of the vineyard-grapes vary in every district; so that were it desirable to procure sorts from France or Germany, only a general order could be given. In this country, however, it would probably, in the event of planting a vineyard, be found preferable to select from the sorts already acclimated, and rendered hardy by many years' culture and propagating from seed, such as the clusters, sweetwaters, espargene, &c. The sorts planted in the vineyard at Painshill, were the Burgundy, or large black cluster, and the miller-grape, or small black cluster. The vineyard-grapes in France, Germany, and Italy, and as we are informed, in Spain, Portugal, and every other wine-country, may be considered as varieties or sub-varieties of the black cluster; and the vines which are grown to produce sweet wines, as the Constantia and Madeira, are only varieties of the clusters, or muscadine.

4836. Making of wine from grapes. The making of wine is a part of domestic economy that can hardly be considered as included under gardening. We shall, therefore, merely suggest, that where grapes are to be pressed in any quantity, the management of the liquor should not, if possible, be left to mere empiric practitioners. Some knowledge of the general principles of fermentation will help to guard against accidents, and direct in doubtful cases. The assistance, therefore, of a person possessing some knowledge of chemistry, or one who has been concerned in the manufacture of British wines, will be found desirable on such occasions. The processes for producing the greatest increases of quality are not yet perfectly known. The first volume of the Memoirs of the Colobian Horticultural Society, by Dr. Macculloch, of Woolwich, Matheus (in the Hort. Trans. ii.), has given a receipt for making a very tolerable sort of red wine from the leaves of the cabernet grape; these leaves, it is suggested, might be employed to give color to wine produced from certain sorts of white grapes, green gooseberries, or other fruits producing a colorless fermented liquor.

4837. Insects which infest the vine. The red spider, of which there are many sorts, attacks the leaves in spring, or early in summer; increases prodigiously in dry weather, and soon damages and destroys the foliage. Speculatively says, red spiders generally reside and breed on the under side of the leaves, and the infested leaves are very distinguishable as soon as they are attacked by them, for the insect wounds the fine capillary vessels with its proboscis, and this causes the upper surface of the leaf to appear full of very small dots, or spots of a light color. When the acari are very numerous, they work a fine web over the whole under side of the leaf; as also round the edges thereof; and it is curious enough to observe, that they commonly carry this web in a straight line, from one angular point of the leaf to another, on which boundary line, in a warm day, they pass and re-pass in very great numbers. Watering is the only effectual means of destroying this insect. (Tu. on the Vine, 162.) The thrips (Thrips, L. Latr. and Leach,) is more injurious to vines in the forcing department than to those in the open air. However, if young shoots chance to receive any injury from late spring frosts, the tender part of the leaf will immediately curl up, and change to a dark-brown color; and in this state, the thrips generally attacks them with great greediness, especially the white sweetwater and white muscadine kinds. The green fly sometimes attacks vines; but seldom so as materially to injure them. Smoking destroys
both insects. There are two or three kinds of coccii, or turtle insect, that sometimes infest the vine, \((\text{Coccus hesperidum and adonidum})\) but they rarely do much injury in the open air.

4836. \textit{The blue fly} (\textit{Musca vomitoria}, Latr.) attacks the fruit when nearly ripe, before the wasp or birds begin to devour it. Forsyth says, “As soon as it makes its appearance, you must provide betimes plenty of bottles, a little more than half filled with some sweet liquor, to entice them to enter and be drowned. Hang the bottles on the nails, at proper distances, all over the vines, and also place some of them at the bottom of the wall.”

4837. \textit{The wasp} (\textit{Vespula vulgaris}), and in some places the hornet (\textit{V. Crabro}, fig. 506), attacks the fruit like the blue fly, and is to be destroyed in a similar manner; or by tying up the bunches in gauze bags.

4838. Birds of various species, but chiefly the smaller kinds which may abound in the neighborhood, also attack grapes. A few of them may be shot and hung up as scarers; or bagging may be adopted; or where there is a full regular crop over the wall, trellis, or standards, the trees may be protected by netting or hunting. The latter will protect them also from the fly and wasp.

\textbf{Subsect. 3.} \textit{Ficus Carica, L.} (\textit{Trew. Ehret.} t. 73, 4.) \textit{Polygam. Dioec. L.} and \textit{Urticeae,} J. Figuer. Fr.; Feigenbaum, Ger.; and \textit{FIGo or Fico,} Ital.

4839. \textit{The fig-tree} is a low tree, a native of Asia and Barbary; naturalised in Italy and the south of France, and enduring the open air in the mildest parts of Britain. The fig-tree in France and Italy grows as large as our apple-trees, but in this country seldom exceeds two yards in height; the trunk is about the thickness of the human arm; the wood, porous and spongy; the bark, ash-colored; the branches smooth with oblong white dots; the leaves annual in Europe, but perennial within the tropics, cordate, ovate, three or five lobed, thick, and the size of the hand. The fruit is a berry, turbinate and hollow within; produced chiefly on the upper part of the shoots of the former year, in the axils of the leaves on small round peduncles. The flower is produced within the fruit; what is considered as the fruit being a common calyx or receptacle: the male flowers are few, and inserted near the opening in the extremity of the receptacle, or fruit; the female flowers are very numerous, and fill the rest of the hollow space within. The greater part prove abortive, both with and without the process of caprisication. The fig forms an important article of culture in the isles and borders of the Mediterranean sea, and especially in Greece, Italy, and Spain. It is also much cultivated for drying in the south of France; and for the table, at Argenteuil, near Paris. The earliest notice we have of its culture in England is by Turner in 1562. The first trees were brought over from Italy by Cardinal Pole, in 1525, during the reign of Henry the Eighth, and yet exist in the gardens of the archbishop at Lambeth. They are of the white Marseilles kind, and still bear delicious fruit. They cover a space of fifty feet in height, and forty in breadth; the circumference of the trunk of two of the trees is twenty-eight, and of another twenty-one inches. In the severe winter of 1813-14, these trees were greatly injured, and in consequence their principal stems were cut over near to the ground; but they are fast recovering. At Oxford, in the garden of the Regius Professor of Hebrew, is a fig-tree, which was brought from Aleppo, and planted by Dr. Pocock, in 1643. It is in a thriving condition, and bears a black fig. Gerrard says, “the fig requires a hot-wall;” and Parkinson, that they are planted in great square tubs, to be removed into the sun in the summer time, and into the house in winter. The culture of the fig was little known here till the time of Miller, who introduced above a dozen new sorts from Italy. He observes, that the generality of Englishmen are not lovers of this fruit, and that, therefore, few trouble themselves with the culture of it. Since Miller’s time, the fig has been introduced to the forcing department, and there cultivated to a much higher degree of perfection than before on open walls; and though it be still true, that a taste for the fig in its green or fresh state is less prevalent in England than elsewhere, yet, by those who have been some time abroad, it is generally much esteemed.

4840. \textit{Monsk} “believes the fig-tree to be of all the fruit-trees which we cultivate in our gardens, the least understood; but, to those who may have acquired a knowledge of its habits, the most tractable. No tree is propagated more easily. I sent from London in April last to Kelsay in Northumberland, two cuttings of figs. They were so small as to travel by the post in a common letter-cover. I have gathered this autumn from one of them three ripe figs, and two from the other. The fig-tree may be checked in its useless habit of luxuriant growth by ringing, so as to become fruitful at a very small size. It may be forced by heat and liquid manure, with copious irrigation, so as to support an abundant crop of fruit, and bring them to perfection, to a greater extent than any other tree. Spare branches of a large fig-tree growing out of doors may be ringed, and surrounded by a small pot of earth, into which they will speedily strike root, so as to bear being separated in autumn from the tree; and they may be used to furnish any glass houses with trees to bear fruit through the next summer. I believe, too, that the fig-tree may be easily propagated by inoculation, if that should be desired.” (\textit{Hort. Trans.} v. 173.)

4841. \textit{Use.} It is cultivated here entirely for the dessert; but in fig-countries it is eaten green or dried, fried or stewed, and in various ways, with or without bread or meat, as food. Abroad the fig is introduced during dinner, as well as at the dessert.
In common with the melon, it is presented after soup; and the person who cuts a fig, holds it by the small end, takes a thin circular slice off the large end, and then peels down the thick skin of the fruit in flakes, making a single bonne bouche of the soft interior part. All the species of the genus Ficus have more or less the quality of intenegrating animal fibre, like the pawpaw-tree (Carica papaya); the F. elásticas in the greatest degree, and next, the common fig. The milky sap may be used as rennet, and for destroying warts. Phillips says, "a gentleman who lately made the experiment, assured me that a haunch of venison, which had lately been killed, was hung up in a fig-tree when the leaves were on, at about ten o'clock in the evening, and was removed before sunrise in the morning, when it was found in a perfect state for cooking, and he adds, that in a few hours more, it would have been in a state of putrefaction." (Pom. Brit. 169.) Burying in the soil for ten or twelve hours is a well known and effectual resource for intenegrating recently killed fowls, or tough butcher-meat.

4842. Varieties. These, in fig-countries, are almost as numerous as those of the grape; new sorts being readily procured from seed, and continued by cuttings, layers, or grafting. Bosc says, that even in France new sorts are continually produced, and as quickly falling into neglect. The various sorts most esteemed in England will ripen as standards under favorable circumstances.

Brown chestnut-colored ischia (island of Ischia). This is one of the largest that we have: it is of a brown or chestnut color, and ripens early within; the grains are large, and the pulp is white, and is not cleanly ripen in August; and if planted again, few two crops may be obtained annually.

Brown Genoa fig. This is a long fruit of the inside being of a bright red, and the flesh is a good one. It may be ripen in the latter end of August.

Large white Genoa fig. (Poll. et Turp. Fr. 256.) This is a large fruit, the skin is thin and yellow when ripe, and red within. It is a good fruit, and ripens in the end of August. This and the preceding bear figs are among the most delicious.

Black ischia fig. This is a middle-sized fruit; the skin is almost black when ripe, and the inside of a deep red. The flesh is high-flavored, and the trees good bearers.

Brown black small Italian figs. These are cultivated in pots; the fruit is small, round, and sweet. Forsyth gathered from one pot a twenty four, two dozen of figs at one gathering.

Malta fig. This is a small brown fig; the skin of a pale brown color, but the same color; the flesh is sweet and highly flavored. It is ripen from the latter end of August to September.

Murray brown Naples fig. This is a pretty large fruit, of a light brown color, and the inside nearly of the same color; the flesh is firm, and sweet, and is highly flavored. It is ripen from the latter end of August to the middle of September.

Green ischia fig. This is an oblong fruit with a green skin; but being thin, is stained through of a brownish cast by the pulp when ripe full ripe. The inside is purple, and is highly flavored. It is ripe about the middle of September.

Maddona, Brunswick, or Hannever fig. This is a large pyramidal fruit; it is the order in which they are bore plentifully, from the middle of August to the end of October.

4843. According to Forsyth, the figs proper for a small garden are the

Large white Genoa | Early white | Murray fig | Small brown ischia | Black ischia

4844. Sawyer recommends for a regular succession of figs from August to October, inclusive, the

Brown ischia, Large white Genoa, Green ischia, Brown Naples, White Marseilles, Black Province, Yellow ischia, and Gentile; which ripen in the order in which they are bore plentifully, from the middle of August to the end of October.

4845. Propagation. Figs may be propagated from seed, cuttings, layers, suckers, roots, and by ingrafting; the most generally approved method is by layers or cuttings, which come into bearing the second, and even the first year.

4846. By seed. Here the same process as that directed for raising seedling vines is to be followed, with this difference, that the young plants should not be cut down on account of their mode of bearing. They will produce fruit in the sixth or seventh year. The process of crossing to obtain new varieties can here be performed easily in the garden, by planting the young trees two or three feet apart in a single row, with a small hair pencil the pollen from the father variety, to take effect in conjunction with that of the male blossoms in the plant destined to bear seed. Possibly, however, some curious horticulturist may find a mode of cutting out the male blossoms without destroying the females; in which case the pollen from the father variety may be introduced to take effect alone. Lee, of Hammer smith, has raised several new sorts from seed.

4847. By cuttings. These are formed of young wood from eight inches to twelve inches in length, with an incision on the under side of the leaf. They should be taken from the healthy, well ripened, short-jointed boughs in autumn, and especially preserved from the frost till spring, or planted in pots or a bed of earth from six to nine inches deep, without cutting off their tops. The soil should be a loam inclining to sand, and in a warm situation; it should be covered with old bark, leaves, or ashes, to keep out the frost in spring, and the drought in summer. If the cuttings have been planted in autumn, then their tops will require the additional protection of haulm or litter during winter. Give water and keep clear of weeds during summer, and by the following autumn, the plants will be fit to be transplanted into nursery rows; where they must be again mulched at root, and protected at top. They require no pruning farther than being required to train them with a single stem, and keep their heads of a regular shape; the second or third year they may be removed to where they are finally to remain. Cuttings of roots readily make plants, but the process is too slow for general use, and the plants so produced are not likely to come into bearing as by layers or cuttings.

4846. By layers. This is the quickest mode of getting bearing trees, as shoots of two or three years' growth, if laid down, will make abundant roots the first summer, and admit of being taken off and placed where they are finally to remain in the autumn. Miller says, "young shoots or suckers produced from old wood, should never be taken, as they are too soft and spongy, liable to be affected by frost, and not likely to prove good bearers."

4849. By suckers. This is an easy, but a bad method, for a common reason, that all trees raised from suckers are subject to great quantities of suckers again from their roots, which branches are never fruitful and fruitful, because too luxuriously to be re-ground in our climate. Miller says, "this vicious habit, contracted while the trees are young, may be afterwards corrected."
FIG. 1

4850. By grafting. This mode can only be advantageously adopted in cases similar to those recommended for grafting the vine. (4851.) The process by any of the modes readily succeeds, and we have seen in Italy above a dozen sorts of figs on one tree.

4851. Culture. For the culture of the fig in the Forcing Department, see Chap. VII. Sect. V. In the open air, the plants are grown as standards, espaliers, and against walls; but, as already observed, the fruit produced in any of these situations is of very inferior flavor to that grown under glass. A crop of figs, Miller observes, is generally more uncertain than that of any other fruit: and Neill says, Britain is certainly not the country for figs. From the attention now paid to this fruit, however, by some eminent horticulturists, we may hope for improvement, and, at any rate, for a more general taste for the fruit.

4852. Soil. The fig-tree thrives in all soils not wet at bottom; but they produce a greater quantity of fruit upon a strong loamy soil than on dry sandy ground, a dry soil being apt to make them cast their figs prematurely. The fig-tree is always propagated from the greater quantities of well-flavored fruit which were growing upon chalky land, where there has been a foot or more of a gentle loamy soil on the top. They also love a open air; for although they will shoot and thrive very well in close places, yet they seldom produce any fruit in such situations.” Smith (Caled. Hort. Mem. vol. ii.), after trying several soils, found the fig-tree thrive best in a rich friable loam, free from latent water at bottom.

4853. Growing the fig as standards. In fig-countries, this tree is always grown as a standard; and here dwarf standards, planted in very warm situations, will, in very favorable seasons, afford tolerable crops of fruit. Some of the best in England are at Arundel Castle; and there is a fig-orchard of 100 trees at Tarring, and another of 14 at Tonting, near Worthing. (Hort. Trans. vol. iv. 545.) Those at Arundel are planted six or eight feet apart, and from a single stem allowed to continue branching into regular conical heads; pruning chiefly irregular and redundant growths, and cutting out decayed or injured wood. Miller states, that often, with figs, with shoots, when growing during winter, generally bear better than those against walls; which, however, may be considered as in great part owing to the mode of training and pruning figs in the latter situation not having then been generally understood. At Argenteuil, where the fig is cultivated in immense quantities for the supply of the table, the plants are grown as dwarf standards; and the chief injury done in keeping them is, the loss of fruit, they enjoy both the heat of the sun and reflection of the earth. The ground is manured occasionally, and stirred at least once a year; and for protection from the frost during the winter, the circumferential low branches are buried six inches in the soil, and in the central ones, as far more figs were produced as standards, they will also thrive against espalier-rails; in which situation they admit of being more readily covered or protected during winter. The plants may be placed at ten or twelve feet distance, and trained in the fan or horizontal manner.

4854. This is unquestionably the best mode for our climate, as it admits of more readily protecting the plants during winter, and is more likely to bring the fruit to maturity in the summer or autumn. The distances at which the plants are placed will depend on the height of the wall. In general, a low wall is to be preferred, both because the fig is naturally adapted for being kept low, and because, when disfigured by the frost during winter, the plants readily recover from fifteen to twenty feet apart, with temporary trees of the fig, peach, or any other fruit between.

4855. Mode of bearing. “The fig-tree,” the Hon. W. Wickham observes, “is distinguished from most, if not from all, other trees, by this extraordinary property, that he bears, and, in warmer climates, brings to maturity, two new crops of fruits in the season; each of these crops of fruits is distinguished by a distinct set of shoots. The shoots, formed by the first or spring sap, put forth figs at every eye, as soon as the second of sap begins to flow again in July and August. These figs (which form the second crop of the year), ripen, in their native climate, during the course of the autumn; but rarely, if ever, come to perfection in England, where, though they cover the branches in great abundance, at the end of that season, they perish, and fall off, with the first severe frosts of winter. The shoots, formed by the second flow of sap, commonly called midsummer shoots, put forth figs in like manner at every eye, but not till the first autumnal flow has set the figs ripening the following spring. As these figs ripen in the winter, in warmer climates, during the months of June and July, but not in this country before September or October. In warmer climates, indeed, very little attention is given to this first crop, because the midsummer shoots, on which it is borne, are commonly in the proportion only of one to six or eight in length, with the autumnal shoots, of which probably six or eight should be allowed in the same proportion, always small, in the same proportion. But in England, it is the reverse. As no care or skill of the gardener can ever ensure a second crop of ripe figs in the open air.”

4856. Pruning and training. Most gardeners, Miller observes, induce the fig-tree shoots to never hang, by cutting away so much of the old wood as will admit of their being all trained in, at full length, and nailed close to the wall, which should always be done before the first severe frosts. Keeping this object in view, the fig-tree may be used very well in cutting away the old wood, nor is there any reason to fear that its free use will either injure the future crops, or deprive the tree of its regular supply of branches. The midsummer shoots being trained in, each year, will produce, in the following...
PRACTICE rolls he make fruit excepting a ceases appear year, and were by par- thernal cultures, either wood or fruit, or both, may be obtained for the succeeding year, at the discretion of the gardener. Where he wishes for wood, he must suffer these new shoots to grow to their full length: where fruit, and not wood, is desired, he must break them in the month of June, in the manner and with the precautions mentioned in Hort. Trans. vol. 34. 4850. Knight disapproves highly of training the branches of fig-trees perpendicularly, as encouraging too much the prolongation of the shoots; he approves of Wickham's mode in warm situations, but in high cold situations, he radiates his branches from the top, and parts near it, a single year, and the figs, from the top, and parts near it, of this, let lateral branches be trained horizontally and pendently, in close contact with the wall. Under such treatment, all troublesome luxuriance of growth will soon disappear, and those parts will be more exposed, and the external figs, produced on those parts which those the buds contain before they unfold. The young wood consequently ceases to elongate very early in the season, and thence acquires perfect maturity; and by being trained close to the wall, is placed secure, or nearly so, from injury by the severest frost. The quantity of mature and perfect figs, which have thus been produced, will become very great, relatively to the size of the tree: and the fruit being in contact with the wall, and not shaded by excess of foliage, acquires an early and perfect matur- ity." (Hort. Trans. vol. iii. 397.)

4850. The Rev. G. Sawyer, from the Rev. W. Sowerby's paper on the culture of the fig-tree, published in the Horti- cultural Transactions, but particularly from that of Wickham, infers, "that the principal defect requiring a remedy is a deficiency of fruitings, or bloom, in the early spring, on the whole of the last year's shoots, excepting on the few joints at their extremities," and he describes a remedy which he has for a long time been in the habit of using, and which he "considers as a specific. It is simply to rub off, as soon as they can be discovered by the naked eye, all the figs which are produced after midsummer on the same year's shoots. The object is not only to prevent those figs which would never ripen without artificial heat in the wall, but to give it sufficient time to employ the strength which would have been employed in ripening those figs. He observes, "in the following year, "If this operation," he says, "be performed in due time, it will not fail to prepare on one, and often on both sides, of almost every fig so displaced, such embryos. For this purpose, the trees should be examined once a-week, from the beginning of August, at which time the figs of this second crop usually appear, as well as examined thoroughly a second time, for this examination will generally make their appearance." Most gardeners, he says, omit removing these late figs at all, or delay the practice till October or November, when no benefit is derived from it. He trains the trees horizontally, and does not prune them till late in the spring, when he can plainly distinguish between a leaf and a fig, the leaves having been removed, and the occasion is thus rendered more evident. (Hort. Trans. vol. iv. 430.) The above practice, in connection with the mode of training recommended by Knight, would, we think, effect an important improvement in the culture of this fruit. Wickham's mode appears to execute too much the function of a tree; and the common mode of fan-training from three or four root-stems, which are in fact so many suckers, is only calculated to produce wood and leaves. Training the fig-tree on walls, as a rider, and in the stellate manner (fig. 386. c), and pinching off all the embroy fruit after midsummer, would probably effect every thing that can be desired in the culture of this tree on the open wall in this country.

4851. Protecting during winter. This is found necessary in many parts of France, and every where in Britain. Miller recommends tying together the branches of standards, and applying pea-haulm, straw, or any other light covering; rolls of reeds to be placed on each side of espaliers, removing these coverings in mild weather, to prevent the figs from coming out too early. Forsyth covers fig-trees against walls with "laurel, yew, fir, or spruce boughs," and then "tucks in short grass or moss among the branches." Smith covers with spruce fir branches, from three to six feet long, fastening them to the wall by the middle rib of the branches, at two different places. "To prevent any friction by the wind, the branches should be made to fit each other, that the covering may be of a regular thickness over every part of the trees. As the covering is generally put on the trees in the month of December, the branches remain green all the winter; and in the month of March, when the days get long, the leaves begin to drop from the branches, and continue falling through April; and by the beginning of May, when the covering is entirely removed, only the ribs of the branches are found remaining. Thus, the progress of the season reduces the coverings in a gradual manner, so as not to expose the trees to any sudden check, which might otherwise be the case, if they were all at once laid open to the weather."

4852. Sawyer, in November, detaches the branches of his fig-trees from the walls, picks off all the autumn fruit that are larger than a filbert, or not of a dark shining green: he then ties the branches of the tree together in bundles forming a sort of cones, filling the interstices with dry hay, and wrapping mats round the whole. After this he lowers the cones to the right and left, and makes them fast to the wall with rope- yard. They remain there during the winter, when they are placed and covered first with treble, then double, and lastly single netting, which last is removed in May. 4853. Mean (Hort. Trans. vol. ii.) adopted the French mode of burying the branches in the soil, in 1759, and has practised it with success since.

4854. Forstel (Hort. Trans. vol. iii. 80.), in respect to covering fig-trees, that "much must be left to the care and skill of the gardener, whose precautions must be determined, as well as varied, by the situation, aspect, and local shelter belonging to each particular tree, and by the varying temperature of each particular day; it may, however, be laid down as a general rule, that the covering, where used, should be thin and light, and that the covering of all the branches of the tree should generally be removed in the day-time, and always on the return of moderate weather.

4855. Ripeing the fruit. Williams suggests that the practice of taking off a circular ring of bark from the upper part of the branches of the trees in the manner he has so near it, of a single stem on the size, might accelerate the maturity of the fruit. Momck tried ringing, and found that it may be practised on the fig-tree with "as much safety, and more effect upon the age of its fruit than on the pear-tree." (Hort. Trans. v. 172.) A very general French practice is to prick the fruit with a straw or quill dipped in olive-oil. In Italy, a wound with a knife is sometimes made on the broad end of the fig, or a very small part of the skin of the fruit removed for the same purpose. Brandy is also sometimes applied, either by a puncture on the side of the fruit with a bodkin dipped in the spirit, or by a small quantity in the eye of the fruit. "Flums and pears," Tournefort observes (Travels, letter viii.), "pricked by insects, "open the faster for it, and the flesh round such puncture is better tasted than the rest. It is not to be day
The process of capfication of figs is performed in the Levant to hasten the maturity of the autumnal crop, and consists in placing on the fig-trees what are called figues-fleurs, or spring figs, in which a certain insect of the gnat species (Culex, L.) has deposited its eggs. From these eggs, in the spring figs, proceed a multitude of young males, which, in their turn, deposit their eggs in the autumn figs, or rather in their flowers, effecting in their passage the fecundation of these flowers, and, by consequence, hastening the maturity of the fruit. The most enlightened French naturalists are of opinion that this is a very unnecessary operation. On the part of the Institute, and author of a Journey through the Ottoman Empire, considers it as "a tribute which man pays to ignorance and prejudice." It is in various countries of the Levant," he says, "it is not performed, nor is it done in France, Italy, or Spain; and it is now neglected in some of the isles of the Archipelago, where it was practised formerly." Bosc says, "the young males of the figs, which are no other than the Pyrale pommonelle, Hubner, (Phaenusa, Linn.) or apple-worm, can be hastening the maturity of the apple: and who would take it upon him to advise rendering apples worm-eaten in order to enjoy the advantage of eating them a fortnight sooner? This observation, it may be observed, rather confirms the above opinion. The particularization lasts maturity, which, from what we have seen in the neighborhood of Rome and Naples, we believe to be the case. Though we think with Olivier, that it is by no means absolutely necessary to fecundation; and even if it were, that fecundation is not essentially requisite to the swelling and ripening of the fig.

4867. Monck has made some curious experiments and observations on this subject, from which he is led to conjecture, 1. That fig-trees never bear figs which contain both kinds of florets in an efficient state; 2. That figs in which the anther-bearing florets only are perfect, never come to be eatable fruit; 3. That you may pronounce, from the external shape of a fig, which kind of floret prevails — the stigma-bearing in the pear-shaped (Fig. 507. a), the anther-bearing in the squat figs (b); 4. That fig-trees, which put forth crops of figs, and cast them, most probably do so from defect of setting. (Hort. Trans. v. 168, 169.)

4868. Insects and diseases. The fig is subject to few of either of these in this country. In forcing-houses it is liable, in common with other plants, to the attacks of the red spider, coccus, and aphides, and occasionally also on garden-walls. The remedies are obvious. In France they are attacked by a species of coccus, vulgarly called the fig-louse, which proves very injurious, and is only to be destroyed by rubbing them off with a coarse cloth.

4869. The melon is a tender annual, producing one of the richest fruits brought to the dessert, and cultivated in England since 1570; but the precise time of its introduction, and the native country of the plant, are both unknown. It was originally brought here from Jamaica, and was, till within the last fifty years, called the musk-melon. The fruit, to be grown to perfection, requires the aid of artificial heat, and glass, throughout every stage of its culture. Its minimum temperature may be estimated at 65°, in which it will germinate and grow; but it requires a heat of from 75° to 80° to ripen its fruit, which, in ordinary cases, it does in four months from the time of sowing the seed.

4870. Varieties. There are numerous varieties, many of which, especially those raised from seeds brought from Italy and Spain, are not worth cultivating. The best sorts are included under the name of cantaloupes, an appellation bestowed on them from a seat of the Pope near Rome, where this variety is supposed to have been originally produced. The general character of the cantaloupes is a roundish form, rough, warty, or netted outer coat; neither very large in fruit or leaves. The Romanus, the Italian sort, next in esteem, are generally oval-shaped, regularly netted; the fruit and leaves middle-sized, and the plants great bearers. Many varieties of both these sorts, however, that were formerly in esteem, are now lost, degenerated, or supplanted by others of Spanish or Persian origin. The following are among the best both of the old and new varieties:

The early golden cantaloupe. It is deep-furrowed, middle-sized, kaputish, golden colored; flesh not very high-flavored nor high-flavored. The plant grows freely, shows early, sets its fruit well; and is one of the finest crops.

The orange cantaloupe. Smaller than the above, and paler, but more mellow. The flesh, when just fitted for cutting, is orange; but when ripe, it is one of the richest and most delicious silver and amber of the harvest. When full grown, and ripened, it becomes partly netted. In respect to flavor, it is said, that it is not quite so mellow kind; being juicy, sugary, and rich. The plant grows freely, an early settler, and a great bearer.

The netted cantaloupe. This is equally juicy and high-flavored as the last-mentioned; a good deal larger, round, somewhat netted, and very ponderous; having a very small vacuum for the seeds; and it may be eaten nearer to the rind than most other kinds. The plant sets freely and is a good bearer.

The silver cantaloupe. Round, of a middle-size, shallow furrowed; and when full-grown, before it begins to color, is black as the loaded silver and amber. It is a very good bearer.

The melon cantaloupe. This is a very large-growing melon; round, black, rather dark green, and a full grown, but yellow when ripe. It is juicy, but not so high-flavored as any other variety of cantaloupe, except the first-named; nor is the plant so good a bearer; nor five or six in a light is a medium crop.

The cantaloupe rock cantaloupe. Two varieties, a large and a small; both very similar to the black rocks, as to color and flavor; but last or cheese-shape, and covered with large protuberances or caruncles. The small kind bears pretty freely, and the large sort less so.

Lee's rock cantaloupe. Rather large than round, and more green than black. The flesh and flavor much the same as those of the late-mentioned variety.

The Italian green-fleshed cantaloupe. Oval, small, nearly so, usually about four inches and a half in diameter, coat pale greenish-white, moderately thin; flesh greenish, soft, and melting in flavor both rich and sweet. (Hort. Trans. iv. 153.)

The smooth scarlet-fleshed cantaloupe. Roundish, inclining to oval; outside greenish-yellow, with fine white vermicular wrinkles; flesh nearly an inch and a half in thickness, of a uniform bright scarlet from the edge of the coat to the centre, and tolerably firm; it is particularly high flavored (Hort. Trans. iv. 529.)
PRACTICE the flesh Gurke, it the fluidity the which this. The green-fleshed Egyptian melon. Middle-sized, round, with thick habits and flavor resembling the last-named variety. (Cucum. melo) or lemon melon. Intermediate in size between them; generally found with the flesh an inch and a half in thickness, not very highly colored, but soft and juicy, commonly setting in the mouth, and with a very sweet and delicate flavor. (Hort. Trans. iv. 210.)

The green-fleshed Ionian cantaloupe. Lemon-colored and lemon-scented; large, thin-skinned, no great bearer, and does not readily mature seeds, but of excellent flavor. (Cucum. melo var. suave.)

The green-fleshed Egyptian melon. Middle-sized, round, with thick habits and flavor resembling the last-named variety. (Cucum. melo) or lemon melon. Intermediate in size between them; generally found with the flesh an inch and a half in thickness, not very highly colored, but soft and juicy, commonly setting in the mouth, and with a very sweet and delicate flavor. (Hort. Trans. iv. 210.)

The green-fleshed Ionian cantaloupe. Lemon-colored and lemon-scented; large, thin-skinned, no great bearer, and does not readily mature seeds, but of excellent flavor. (Cucum. melo var. suave.)

8471. Choice of seed. In the cultivation of the melon, Knight observes, it is a matter of much importance to procure proper seed. Some gardeners are so scrupulous on this point that they will not sow the seeds unless they have seen and tasted the fruit which from which they were taken. It is proper at least not to trust to seeds which have not been collected by judicious persons. Some make it a rule to preserve always the seeds of those individual specimens which are first ripe, and even to take them from the riper side of the fruit. A criterion of the goodness and probable fertility is generally sought by throwing them into a vessel containing water; such as sink are considered as good and likely to prove fertile, those that float, as effete. It is remarked of seeds brought from the continent, that they must have more bottom heat, and the young plants less water, than are necessary for seeds ripened in this country, or young plants sprung from these.

8475. Varieties. The principal of these are:

Early long prickly; from five to seven inches long; of a green color with few prickles. The plant is a good bearer; and the fruit is accounted the best cucumber for the general summer crop, the pulp being very crisp and pleasant.

Longest green prickly; from seven to ten inches in length; it has dark-green skin, closely set with small prickles. This is, a hardly sort, but does not come early.

Early short prickly; not more than four inches long; the skin green, rather smooth, but with a few small black prickles. This is one of the hardiest and earliest sorts, and is often preferred for the first crop. Ditch, or white short prickly, though not much cultivated, is recommended by some, as preferable even to the early long prickly; it has fewer seeds; is evidently different in taste from most other cucumbers, but of agreeable flavor. Ditch cucumber; a very early sort, the flowers appear in clusters of three or four together; the fruit is seldom more than five inches long; it is at first of a dark green color, but becomes yellowish as it ripens. The stems of this variety are much inclined to climb; in most of their tendrils upon sticks; the leaves are small, and the plant altogether occupies but little room.
EXOTIC FRUITS.

Book I.

Smooth green Roman; an early sort; the fruit becomes large and long, and is quite smooth; the plants grow very strong, and require a good deal of room.

White Turkey; the stalks and leaves are large; the fruit is round, and the other varieties of the fruit also is very long, sometimes from ten to fifteen or even twenty inches; it is quite straight, and has a smooth skin; the fruit is delicious springing, and late in the season.

4576. Culture. The culture of the cucumber, as a table-esculent, is chiefly carried on by artificial heat or protection, and is therefore treated of under the Forcing Department, Chap. VII. Sect. VII. For picking, it is chiefly cultivated in the open ground by what is termed dripping, and which forms the only branch of the culture of this vegetable reserved for this article. To have a crop in the natural ground, the seed is sown in warm compartments of rich earth, towards the end of May, or beginning of June, when the weather is settled, warm, and dry. The plants should mostly remain where sown, to produce late fruit, towards which end the soil is kept as wholesome as possible, and the shade and shelter so managed, and in large open compartments for ordinary consumption. Sow a portion in a warm border, and the main crop in an open compartment. Dig the ground neatly even. Trace lines with intervals of five or six feet; and in the lines mark stations three and a half feet distant; then, with a trowel at each of these spots, form shallow circular-surfacedquam in the surface, ten or twelve inches wide, and about an inch deep in the middle. Sow in the middle of each cavity eight or ten seeds, half an inch deep. When the plants are come up, and begin to put forth the first rough leaves in the centre, thin them to three or four of the strongest in each hole.Earth these up a little, between the close round leaves, pressing them a little a sandier, and give them some water, to settle the earth below and above. In their advancing growth, train out the leading runners. Supply them with requisite waterings, in dry weather, two or three times a week, or sometimes every day in very dry hot weather, in July, August, or September. At this season, water them in the morning, or late in the afternoon, towards evening.

4577. Gathering. The crop comes in sometimes towards the end of July, but more generally not before August in full production; continuing till about the middle or end of September, when the plants decline. Be careful to gather the fruit in a prime state, both for picking and other purposes. They must be quite young for picking, not exceeding two or three inches in length. (Decteroumica.)

Sect. II. Exotic Fruits, well known, but neglected as such.

4878. Among neglected exotic fruits we include the orange tribe, one of the most beautiful, and also, very a useful class of fruits. The culture of oranges and lemons for the table is not at present common in England; but, in our opinion, it might be pursued with much enjoyment to the amateur, since, independently of the gratification of seeing fruit of one’s own growth at the dessert, no object of the fruit-tree kind can be more splendid than a large healthy orange-tree covered with fruit. The pomegranate seems also to merit culture, both for its singular beauty while on the tree, and the addition it would make to the dessert.

4879. Of the genus Citrus there are five species or leading sorts, of which the fruit are used; all natives of Asia, viz. the common orange, the lemon, the citron, the lime, and the shaddock. The common character of the plants bearing these fruits is that of low evergreen trees, with ovate or oval-laureolate, entire or serrated, leaves. On the ungrafted trees are often axillary spines. The flowers appear in peduncles, axillary or terminating, and one or many flowered. The fruits are large berries, round or oblong, and generally of a yellow color. The species seem best distinguished by the petiole, which, in the orange and shaddock, is winged; in the citron, lemon, and lime, naked. The form of the fruit, although not quite constant, may also serve for a distinction. In the orange and shaddock, it is spherical, or rather an oblate spheroid, with a red or orange-colored rind; in the lime, spherical, with a pale rind; in the lemon, oblong, rough, with a nipple-like protuberance at the end; in the citron, oblong, with a very thick rind. The flowers of the citron and lemon have ten stamens, and those of the orange more. Professor Martyn observes, that it is very difficult to determine what is a variety, and what is a species in this genus. The trees in the eastern countries, where they are natives, vary in the size and shape of the fruit and leaves; and many of those considered varieties in Europe, preserve their differences in their native woods. He has no doubt that any one who would pursue this subject in the native countries of these fruits, would detect varieties connecting all those generally considered as species. This opinion appears highly probable when we examine the catalogues of the continental writers on this fruit; who, in general, finding it difficult to make botanical distinctions, are obliged to rest satisfied with popular descriptions. In Nouveau Cours, &c. art. Orange, those cultivated in France, and in Dr. Sickler’s work, and that of Gallesio, those of Italy, are so described.

4880. Dr. Sickler, who spent several years in Italy, and paid great attention to the kinds and culture of the orange, published in 1815, Der Vollkommen Orangierie-Gartner (The Complete Orange-Gardener), in which he describes above seventy sorts of Citrus, including all the species above mentioned. He arranges the whole in two classes, and these classes into divisions and subdivisions, without regard to their botanical distinctions or species, thus: —

The names and some descriptive traits of these seventy-four sorts of citrus will be found in *A Short Delineation of Dr. Sickler's Treatise, by Dr. Noehden*, in the *Hort. Trans.* vol. iii. App.

4881. Gallesio (*Traité du Genus Citrus, &c.* Savonna, 1818.) has given a synoptic tree (fig. 509.), in which he has introduced ramifications which display an arrangement of the forty principal sorts cultivated in Italy.

509

4882. *The most splendid work on oranges which has yet appeared is the Histoire Naturelle des Orangers, by Risso, of Nice, and Poiteau, of Versailles. (Paris, fol. 1818.) Here 169 sorts are described, and 105 of them figured, and their French and Italian culture given at great length. They are arranged as sweet oranges, of which they describe 43 sorts; bitter and sour oranges, 32 sorts; bergamots, 5 sorts; limes, 8 sorts; shadocks, 6 sorts; lumes, 12 sorts; lemons, 46 sorts; citrons, 17 sorts.*

4883. *All the species of citrus endure the open air at Nice, Genoa, and Naples; but at Florence and Milan, and often at Rome, they require protection during the winter, and are generally placed in conservatories and sheds. The largest conservatory in Italy is that of Prince Antonio Borghese, at Rome, which contains seventy select sorts of agrumi. The largest trees are at Sorenta, Teracina, Gaeta, and Naples; but the most regular and garden-like culture of the orange, is in the orange-orchards at Nervi, Monaco, and other places in the neighborhood of Genoa. At Nervi are also the orange-nurseries which may be said to supply all Europe with trees; they are, in general, wretchedly cultivated, and the stocks inoculated in the most unscientific manner; but the fine climate, strong clayey soil, and abundant manurings, supply in a great degree the nicer practices of gardening. There the names of varieties vary as much as those of gooseberries do in England; but from upwards of one hundred names, not above forty distinct sorts can be procured. Good plants of the Maltese and other varieties of orange may be procured from Malta; and some sorts also from Lisbon. From the nurseries*
at Paris about thirty sorts may be obtained, much smaller plants than those from the other places named, but more scientifically grafted or inoculated. At Vallet's nursery at Rouen, is a collection of very large plants of the common kinds. The catalogues of London nurserymen enumerate above thirty varieties of orange, twelve of lemon, and several varieties of the other species; the plants are generally inoculated, and small, and are more calculated for pots than for planting in the soil for producing fruit. As being most useful for the British horticulturist, we shall place under each species the names of the varieties which may be procured in England.

4584. The common orange is the Citrus Aurantium, L.; the orange of the French; pomarance of the Germans; and arancio of the Italians. (fig. 510.) It is a middle-sized evergreen tree with a greenish-brown bark; and in its wild state, with prickly branches. The fruit is nearly round, from two to three inches in diameter, and of a gold color. It is a native of India and China, but now cultivated in most countries of Europe; in the open air in Italy and Spain; and in conservatories or green-houses in Britain and the north of Europe. The orange is supposed to have been introduced into Italy in the fourteenth century, above a thousand years after the citron. In England, the tree was first cultivated since 1629. Parkinson writing at that time, says, "it hath abidden with some extraordinary looking and tending, when neither citron nor lemon trees could be preserved any length of time."

4585. The orange-trees of Boddington, in Surrey, introduced from Italy by a knight of the noble family of the Carewens (Gibson's edit. of Camb. Brit.), were the first that were brought into England; they were planted in the open ground, placed under a movable cover during the winter months, and they had been growing there before 1295. It has been said, that these trees were raised by Sir Francis Carew, from seeds brought to England by Sir Walter Raleigh; but such trees would not have readily borne fruit, Professor Martyn thinks it much more likely that they were plants brought from Italy. Bradley says, they always bore fruit in great plenty and perfection; that they grew on the outside of a wall, not nailed against it, but at full liberty to spread; they were planted at a distance of twenty-nine lines, and the spreading of the branches one way nine feet, and twelve feet another. These trees, Evelyn informs us, were neglected in his time during the minority of their owner, and finally entirely killed by the great frost in 1739-40. 

4586. During the latter end of the seventeenth and beginning of the eighteenth century, the orange-tree was considered an article of growth in conservatories, when there were but few exotics of other sorts kept there. The plants were procured from Genoa, with stems generally from four to six feet in height; they were planted in large boxes, and were set out during summer to decorate the walks near the house in the open air. Von Vauley mentions about the middle of the eighteenth century, when a taste for botany and forcing exotic fruits became general, that, for superb orange-trees began to decline; many of these large trees have decayed through neglect; and those which are now to be found in the greater number of green-houses, are generally dwarf plants bearing few fruit, and those of small size black and small. Some are found large and flourishing trees. Those at Smurgy in Glengarnachie, are the largest in Britain; they are planted in the floor of an immense conservatory, and bear abundantly. It is said that the plants were procured from a wreck on the coast in that quarter, in the time of Henry VII.

4587. At Nuneham, near Oxford, are some very fine trees, planted under a moveable case, sheltered by a north wall. In summer, the case is removed, and the ground trenched over, so that the whole resembles a native orange-grove. At Wormleybury, Hertfordshire, and Shipley Hall, in Derbyshire, are very fine large orange and lemon trees grown in borders and in boxes. (Hort. Trans. vol. ii. 285. and iv. 906.) With the Carewens' are three trees in boxes, not surpassed by any trees so grown in Europe. C. Bingham, at Isleworth, possesses a very fine collection; and various others might be enumerated.

4588. At Woodhall, near Hamilton, trees of all the species of citrus are trained against the back wall of forcing-houses, in the manner of peaches, and produce large crops of fruit.

4590. In the south of Devonshire, and particularly at Salcombe, one of the warmest spots in England, may be seen, in a few gardens, orange-trees that have withstood the winter in the open air upon the coast of the Italians; and the bitter or Seville, the bigarade of the French, and arancio volgare of the Italians. The Maltese orange, distinguished by its red pulp, is also a noted and much-esteem'd sort. The box-leaved, willow-leaved, and some others, are cultivated more as curious varieties than for their fruit.
4893. The Citron is the C. Medica, L. (Ger. fru. 2. t. 121. f. 2.); the citron of the French; the citronier of the Germans; and cedrate of the Italians. (fig. 512.) In its wild state the tree grows to the height of about eight feet, erect and prickly, with long reclining branches. The leaves are ovate, oblong, alternate, subsperrate, smooth, pale green. The fruit or berry is half a foot in length, ovate, with a protuberance at the tip. There are two rinds, the outer thin, with innumerable miliary glands, full of a most fragrant oil; the inner, thick, white, and fungous. The citron was introduced into Europe from Media, under the name of malus medica, and was first cultivated in Italy by Palladius in the second century. The date of its introduction into England is not exactly known; it would probably be coeval with that of the lemon, which was cultivated in the botanic garden at Oxford in 1648. The fairest fruit, Miller states, was in the Duke of Argyle’s garden at Whiston, where the trees were trained against a south wall, through which there were flues for warming the air in winter, and glass covers put over them, when the weather began to be cold. Thus the fruit was as large and as perfectly ripe, as it is in Italy or Spain. In Italy citrins and lemons are generally trained on walls or espaliers, because, being considerably more tender than the orange, they require, at least in the north of Italy, some protection in winter; the fruit does not ripen regularly at one time, like that of the orange, but comes successively to maturity almost every month in the year.

4894. Its use. The fruit is seldom brought to the dessert in a raw state, but it forms excellent preserves and sweetmeats, to furnish the table when other fruits are scarce. The juice, with sugar and water, forms lemonade, a most refreshing, salubrious, and universally esteemed beverage. Its use in punch and negus is well known. It is much used in medicine, and also in perfumery and dyeing.

4895. Varieties. Dr. Sickler enumerates only about a dozen citrons and citronates as grown in Italy. The French nurseries have nearly twenty names in their lists. In England the six following are cultivated for sale:—

The common citron | The rough-fruited | The grape-fruited Barbadoes | The round-fruited (Hort. Trans. vol. iii. p. 358.) | The thick-leaved.
---|---|---|---|---

4896. The lemon is the C. Medica, var. Limon, W. (Blackwood 392.); the limon of the French; limonier of the Germans; and limone of the Italians. (fig. 513.) The distinction between the lemon and citron is very trifling. The fruit is less knobbed at the extremities, is rather longer, and more irregular, and the skin is thinner than in the citron; the wood is more knotty, and the bark rougher. Cultivated in the Oxford garden in 1618.

4897. The uses of the lemon are the same as those of the citron.

4898. Varieties. Dr. Sickler enumerates twenty-eight as grown in Italy. The French, according to Ville Hervé, have eleven sorts; in the London nurseries are cultivated the twelve following:—

5909. The lime is the Citrus Acidia, Rox. (Brown's Jam. 538.) by some esteemed a variety of the C. Medica; the lime of the French, Italians, and Germans. (fig. 515.) The sour lemon, or lime, grows to the height of about eight feet, with a crooked trunk, and many difused branches, with prickles. The leaves are ovate, lanceolate, almost quite entire. Berry an inch and a half in diameter, almost globular, with a thick and firm rind, at the top; the surface regular, shining, greenish-yellow, with a very odorous rind, enclosing a very acid juice. It is a native of Asia, but has long been cultivated in the West Indies, where it is grown both for its fruit and for fences.

5900. The uses of the lime are the same as those of the lemon, to which, in the West Indies, it is preferred; the juice being regarded as more wholesome, and the acid more agreeable to the palate.

5901. Varieties. By the catalogue in Nouveau Cours, &c. the French have two sorts of lime; and according to Dr. Sickler, the French have the variety at the top; the surface regular, shining, greenish-yellow, with a very odorous rind, enclosing a very acid juice. It is a native of Asia, but has long been cultivated in the West Indies, where it is grown both for its fruit and for fences.

5902. The shaddock is the C. decumana, W. (Rump, am. 2. t. 24. f. 2;) the orange pamplemouse of the French; and the arancio massimo of the Italians. (fig. 516.) The tree is above the middle size, with spreading prickly branches. The leaves are ovate, subacute, seldom obtuse; the petioles are cordate, winged; the wings as broad as the leaves. The berry spherical, with an even surface, and greenish-yellow color; pulp, red or white; juice, sweet or acid; rind, white, thick, fagous, and bitter. Thumberg says, the fruit in Japan grows to the size of a child's head, and, Dr. Sickler states its weight as fourteen pounds, and its diameter as seven to eight inches. It is a native of China and Japan, and was brought to the West Indies by Captain Shaddock, from which name the tree derives. In the West Indies it was sent to England, and cultivated by Miller in 1739.

5903. Use. The shaddock is certainly the least useful of the species enumerated, and is cultivated chiefly for show. It has the handsomest leaf of the whole tribe, and the fruit is larger than the orange. Where several sorts of oranges are presented at the dessert, it makes a striking addition to the variety. The juice is of a subacid sweetness, and excellent for quenching thirst; and the fruit, from the thickness of its skin, will keep longer in sea voyages than any of the other species of citrus.

5904. Varieties. The Italians, according to Dr. Sickler, have one; and the French, according to the catalogue in Nouveau Cours, &c. four sorts. The following four are grown in the English nurseries:

<table>
<thead>
<tr>
<th>The common shaddock</th>
<th>The rough-fruited</th>
<th>The largest-fruited</th>
<th>The West India</th>

</thead>
</table>

5905. Propagation of the citrus tribe. All the sorts may be propagated by seeds, cuttings, layers, and grafting, or inoculation.

5906. By seed. The object of raising plants from seed is either to obtain new varieties or stocks for grafting. To attempt raising new varieties in Britain will in general be found a tedious process, as the trees do not even in Italy show fruit for six or eight years or more; and there is now in the botanical garden at Toulon, a large handsome tree, of twenty-five years growth, which had not in 1819 been incummoned. However, if new varieties are attempted, select the largest and best-formed ripe fruit of the kind to be raised, extract the seeds, dry them, and sow and nurse as hereafter directed for raising stocks. Where trees are to be raised for stocks to bud oranges, Miller advises to procure citrus-seeds, as stocks from these are preferable to any other for quickness of growth; and also that they will take buds of either orange, lemon, or citron. Next to these are the Seville orange seeds; and the best of either sort are to be had from rotten fruits. Prepare in spring a good hot-bed of dung or tan, and when it is in moderate temper sow the seeds in pots of light earth; plunge them, give water frequently, and raise the glasses in the heat of the day. In three weeks the seeds will come up, and in a month's time be fit to transplant into single pots. Then renew the bed, and fill pots of five inches in diameter half full of good fresh earth, mixed with very rotten cow-dung: shake out the seedlings, and plant one in each pot, filling it up with the same earth, and replunge as before. Give a good watering to the roots, and repeat this often, as the orange tribe in a hot-bed require a good supply of water. Shade in the day-time, when the sun is powerful, and give air so as not to draw the plants. By this method, with due care, the plants will be two feet high by July, when they must be hardened by degrees, by raising the glasses very high, and afterwards, in fine days, taking them entirely off, shading the plants with the upper screen; thenwards the end of September, house them in a dry part of the green-house, near the glass, where they will not be liable to damp off. During winter refresh them with water, and in April now and then wash their stems and leaves, to clear them from any filth they may have contracted. Place them again in a moderate hot-bed, and harden them by the beginning of June, that they may be in a right order to bud in August.

5907. Budding. Make choice of cuttings from trees, that are healthy and fruitful, observing that the shoots are round; the buds of these being more perfect and tender than those of the shoots are flat or angular. After performing the operation, remove the plants into the green-house, or under glass frames, to defend them from wet, turning the buds from the sun; but let them have as much free air as possible, and refresh them often with water. In a month it will be observables which has taken, and then let them in the green-house all the winter. In spring cut off the stocks about three inches above the buds, and place them in a moderate hot-bed, giving air and water, and shading as before. By the end of July they will have made shoots of two feet or more; then harden them before the cold sets in, that they may the better stand the winter. In the first winter after their shooting, you must keep them very warm, for by forcing them thus you may overheat them, but it is very necessary to raise them to their height in one season, that their stems may be straight, for in trees which are two or more years growing to their heading height, the stems are always crooked. In the succeeding years their management will be the same as for full-grown trees.

5908. The Italian process of raising and budding. In the orange-nurseries at Nervi.
the seeds of the citron or orange, as it may happen, are sown in beds in the open ground in February or March, and in September planted out in compartments, in rows generally about eighteen inches wide, and the plants six or eight inches in the row. They are placed thus close to draw them up with clean straight stems. There they remain generally four years, and in April or May of the fifth year they are taken up, their roots cut within four or six inches of the tap-root, which is also shortened to six or eight inches, according to the size of the tree. The stem, if it has any side shoots, is pruned clean, and sawn off horizontally, at such a height as that the section is from half an inch to an inch in diameter. (fig. 517. a) The general heights are one foot, which forms the lowest-growing plants; eighteen inches for trees to be sold in Italy; from two to four feet for trees to be sent abroad; and five or six feet for extraordinary orders. These last are not so common; as the stocks require six or eight years' growth, and some care to attain that height with clean stems, and a diameter of three quarters of an inch. The plants thus pruned are budded, sometimes when out of ground, and sometimes after planting. One bud is inserted on each side of the stock (c), within an inch of the section. In a month buds and roots begin to push, and in December or January following these plants are in fit state for taking up for exportation. After being taken up, the roots, now well furnished with fibres, are enveloped in a ball of stiff clay; this is covered with moss carefully tied on, and in this way they are laid in boxes, or in casks, and sent not only to most parts of Europe, but to North and South America.

The chief defect in this system is the naked horizontal section at the top of the stem (a), which, not being smoothed with the knife and covered with clay or any other protection, to cause the bark to grow over it, indurates and cracks with the drought; retains moisture and decays, so that in almost all trees that have been budded in this way, a dead stump or a rotten hole, may be observed during the whole period of their existence. This evil is often lessened by covering with a cap of lead or a patch of wax; but it might readily be obviated by peeling off a piece of bark from one side of the part of the stock to be sawn off (d), letting it remain attached to the lower part of stem; and after removing the head, bringing it down close over the section, inserting its end under the bark in the opposite side, somewhat in the manner of saddle-grafting; or the manner employed by surgeons in amputating a limb (e) might be adopted. A similar object might probably be effected by removing a wedge-shaped section from the top of the stock (f), and then compressing its sides, so as to present a wedge-shaped termination covered with bark (g). But the gardeners at Nervi are too indolent and obstinate to hear of any thing new, and will persist in their present plan till the credit of Genoa for orange-trees is gone, or till some strong necessity urges them to improvement.

2999. The Maltese, aware of the defects in Italian trees, make a sloping section (b), paring it clean, and budding on one side only; the consequence of which is, that the section becomes covered with bark, and, which it never does in the Italian method, as sound and healthy as any part of the stem. The French graft and inoculate in a very neat manner (c), and indeed their orange-trees, though small, are much handsomer than the Italian ones.

5010. By grafting. This mode is occasionally resorted to in Italy, and is that most generally adopted in the nurseries at Paris. The stocks, when of two years' growth, and not much thicker than the scion, are cut over within six inches of the ground, and then grafted in the whip manner. The trees continue small, but have clean stems of from one to three feet, and generally make handsome plants, prolific in flowers and fruit, of a small size. Grafting, both by the whip manner and by approach, is frequently practised in England, in nearly the same circumstances of age, size, and effect, as practised in France. A variety of the whip-manner is described by Cushing, in which the top of the stock is left on, but the scion is cut off as in grafting. "Form the scion as for the common whip-graft, and then, without taking off the braid or whip of stock, cut from one of its stem an equal splice as smoothly as possible; do not tongue the scion, but tie it on neatly and firmly with matting and clay, in the manner of a graft: plunge them in a hot-bed, and cover with a cap-glass till the scion begins to grow, and then cut away the top of the stock, and remove the matting by degrees." (Exotic Gard. 103.)

5011. Whip-grafting in the common way has lately been successfully performed, even with fruit or flowers on the scion, by Nairn, who gives the following account of the process: "Let the operator select as many orange or lemon stocks as he wishes to work, and place them on a moderate hot-bed for a fortnight, by which time the sap will have risen sufficiently to move the bark; the stocks must then be cut off, about two inches above the surface of the pot, and an incision made with a sharp knife, similar to what is done for budding, separating the bark from the wood on each side. Let the scion be cut thin, in a sloping direction, and thrust between the bark and wood, and then bound tight with woolen yarn; but very great care must be taken, in binding, to prevent the bark from slipping round the stock, which, without attention, it is very apt to do. After it is properly and neatly bound, put a little loam or clay
close round the stock, to the surface of the pot, then, with a glass of a proper form (fig. 518), to prevent the damp from dripping on the scion, cover the whole, and press it firmly but not too strongly, to prevent the air or steam from getting to the plant; the glass must not be taken off, unless you find any of the leaves damping, and then only till this is remedied, when it must be immediately returned. The stocks must next be placed on a brisk hot-bed of dung, and in about a month, the glasses may be taken off, and the clay and binding removed; but it will be necessary to bind on a little damp moss, in lieu of the clay, and to keep the glasses on in the heat of the day, taking them off only in about three weeks or a month, they will be fit to be put into the green-house, where they will be found to be one of the greatest ornaments it can receive. I should recommend the mandarin orange for the first trial, as the fruit is more firmly fixed than that of any of the other greens.

I have, by the above method, had seven oranges on a plant, in a pot, commonly called a small sixty, which I conceive to be both curious and handsome." (Hort. Trans. iii.)

5912. Henderson's mode of grafting is well adapted for proving successful. "Take two sprigged cuttings, cut into lengths of about seven inches. If the stock is much thicker than the graft (fig. 519. a), cut a piece out of the stock of a triangular figure, about an inch and two eighths in length, regulating the depth according to the thickness of the graft, and keeping it square at the bottom. Displace two leaves at the bottom of the graft, for the convenience of getting it put on, cut the graft right across under one eye, where a leaf has been taken off; dress the graft to fit the receptacle made in the stock, observing to keep the lower end of the graft equal in thickness as above; always let three or four leaves remain untouched on the graft. After the graft is fitted in the stock, tie it up with bass matting, and put clay around it. If the grafts and stocks are nearly of the same thickness (b), cut the stock, at right angles, nearly half through. Cut off the piece, keeping it equal at top and bottom: cut the lower end of the graft right across under an eye (c), and with a knife prepare the graft to fit the stock. When the grafted plants are tied up and clayed, set them at the back of the vineyard or peach-house, observing to keep them away from the flies, as fro-heat is hurtful to them at first; cover them with hand-glasses, or, if a frame can be spared, it is still better. Shade them every day, but take the mats off at night; continue the shading till they begin to grow, when they may be exposed to the light. If any stock happens to be so tall and thick that it cannot be placed under a hand-glass or frame, put two or three glasses on it, set in any convenient place in the house, and shade it with mats; it will succeed perfectly in this way, the grafts lose none of the old leaves; and even in five or six months, they will make three or four young shoots six or eight inches long; these, with the leaves that were on the grafts when put on, form a well-clothed little plant.

5913. By cuttings. This method, though little practised on the continent, where the object is large trees and fine fruit, is frequently adopted by the English gardeners, whose object is, usually, small handsome plants. Two methods are adopted; the first is to take young succulent wood as soon as it has done growing, and the lower end has become somewhat mature. These cuttings, prepared properly (5914.) are inserted with a small dibber in pots of light sandy loam, with two or three inches of gravel or broken pots at bottom. They are then covered with a crust of fine sand, and plunged in a gentle heat, and shaded. The glasses are taken off only to wipe them when damp, and to remove any decaying leaves. In two months such cuttings either strike or rot off. The second method is in spring to take the shoots of last year; to prepare and plant them as above; but after covering them with glasses to plunge them in a cold-frame, where they remain in a state of apparent inaction for three or four months, when they either form a callosous excrescence at the lower end of the cutting and push at top, or die off. After preserving them in a low cold frame through the winter, they are placed up to the depth of the dibber, the cuttings being put in, so that the short ends are pointed to one side, and those that are taller in a different pot. Then, with a small dibble, plant them about five inches deep in the sand, and give them a good watering overhead, to settle the sand about them. Let them stand a day or two in a shady place, and if a frame be ready with bottom heat, plunge the pots to the brim. Shade them with matting for a month or two, till they have struck root; when rooted, take the sand and cuttings out of the pot, and plant them into single pots, in the proper compost (see 5922.) Plunge the pots with the young plants again into a frame, and shade them for four or five weeks, or till they are taken with the pots; when they may be gradually exposed to the light. From various experiments, I found that pieces of two- or three-year-old wood struck quite well; and in place, therefore, of putting in cuttings six or eight inches long, I have taken off cuttings from ten inches to two feet long, and struck them
PRACTICE
neither
so
To "heat." the material animals. Noehden on they seven hundred cow-dung. and following mended budding very be the soil; and the plants which is wholly covered with branches. Where laying is adopted, the plants may either be laid down on their sides, and laid as stools, or pots may be raised and supported under the branches to be propagated from. These branches, or shoots of one or two years' growth, may then be transplanted to the place where the bottom is to be built through the same manner, taking care to supply water with the greatest regularity. Shoots layered in March will be fit to separate from the stools as mother plants in the September following. In general, it may be observed, that the citron tribe, like other fruit-bearing plants raised from cuttings or layers, though they may prove valuable and handsome, yet yield fruits both with that vigor, and produce such large fruit, as those propagated by budding or grafting on seedling stocks.

16. Soil. At Genoa and Florence they are grown in a strong yellow clay, which is richly manured; and this soil is considered by the first Italian gardeners, as best suited to their natures. At Rome and Milan the natural soil is lighter; but a strong soil is adopted generally for all the agrumi, and particularly in the garden of His Holiness the Pope. At Naples, where the trees are always planted in the open ground, the soil is lighter and of volcanic origin. A strong soil, in imitation of that of Nervi, is recommended and adopted by the Dutch. (See seu Osten, Nicol, Hesperides, &c.)

17. The French gardeners, according to Bosc (in N. Cours d'Ag. in loco), in preparing the compost for the orange-tree, endeavor to compensate for quality by quantity; because the pots or boxes in which the plants are placed ought always to be as small as possible, relatively to the size of the tree. The following is Bosc's prescription: Take equal parts of a fresh cow-dung, and of a third part of vegetable matter, and which has lain a long time in a heap, add an equal bulk of half-rotten cow-dung. The following year turn it over twice. The succeeding year mix it with nearly one half its bulk of decomposed horse-dung. Take every other year or three times, before using, add a twelfth part of sheep-dung, a twelfth part of pigeon-dung, and a twelfth part of dried ordure.

18. Miller says, the best compost for orange-trees is two thirds of fresh earth from a good pasture, and one third of neat's dung. These should be mixed together at least twelve months before using, turning it over two or three times. Mix it well with a handful of the swill of the entire house, then spread it over the place where the plants are to be raised. (M'Phail and Abercrombie recommend "three eight parts of cow-dung, which has been kept three or four years; a fourth part of vegetable mould from tree-leaves; one sixth part of fine rich loam; and one twelfth part of road-grit; to this may be added one eighth part of sheep-dung." (G. Renn, 242, P. 95.)

19. Mean has tried the following mixture (Hort. Trans. ii. 295.), and with which he has "every reason to be satisfied." Well-prepared rotten leaves, two to three years old, one half; rotten cow-dung, two, three, and four years old, one fourth; mellow loam, one fourth; with a small quantity of sand or rice-harvest, which must not to be added to the compost, without injury, yet, as Mean has observed, the leaves once injured the trees will require three years to recover their appearance. Ayres never suffers his orangey to be heated above 50° by fire-heat, until the end of February; when the trees show blossom, it is increased to 55°, but never allowed to exceed 60° by sun-heat, which he considers as quite sufficient, to give the plant its constitution; and begins to force the trees, by keeping the heat in the house up as near as possible to 75°. For I do not consider (he adds) that either citrons, oranges, lemons, or limes, can be grown fine and good with less heat. (Hort. Trans. iv. 811.) The orange, Humboldt observes (De Distrib. Plant. 158.), which requires an average temperature of 54° and 59°, would bear a degree of 56° even if continued over a long time. This is proved by an observation of Dr. Sickler, who says, "It is remarkable how much cold and snow the common lemons and oranges will bear at Rome, provided they are planted in a sheltered situation, not much exposed for the winter. Thus I saw in the two winters of 1805 and 1806, under my window on Mt. Placente, three standard orange-trees in the open ground, heavily covered with snow for more than a week. The green leaves, but still more the golden fruits, nearly ripe, looked singular but beautiful amidst the snow; neither fruits nor trees suffered, being in a sheltered place, while many branches and leaves of other trees, which were exposed to the frost, were dead. I never observed any of these trees to be the whole tree sickly." (Volk. Oratt. Gatt. 9.) It appears that the snow had been thawed off these trees gradually, and more by the temperature of the atmosphere than by the direct rays of the sun, or a current of heated air. This resulted from their sheltered and partially shaded situation; and, as Dr. Nordenha has observed, the heat of the air is preserved in the orange, it prevents the violence of the sudden transition from cold to hot, and the contrary, than the degree of either, which destroys vegetables. Whenever orange-trees or any tender exotics have been touched during night by frost, they should either be immediately shaded by the leaves of the next smaller size, or on 30 or 35 degrees of temperature. In the northern regions the same treatment is successfully applied to animals. (See Hort. Trans. iii. 42, and 114.)

54. Water. Orange-trees, like other evergreens which delight in a strong soil, are not naturally fond of a great deal of water; yet, on this account, are often suffered to dry up the earth; the water tends to the earth becoming indurated, the water wets only the surface, and runs over and escapes by the sides of the pot or box; so that while the mass of earth below is dry, the surface has a same moist appearance. Mean says, "When I think from the appearance of a plant, that the water does not freely penetrate the earth, I moisten it from the bottom, with a can of red, and the water, running down from top to bottom of the earth, and to form a channel for the water, too little or too much of which is equally injurious to orange-trees." Knight (Hort. Trans. ii. 298.) watered an orange-tree with very strong liquid manure, and found it grow with equal comparative vigor to the vine and mulberry. Ayres, after the fruit is set, waters with water, in which, at the rate of three barrows of fresh cow-dung, without litter, two barrows of fresh sheep's droppings, and two pecks of quick lime have been added to every hoghead; when
used, the water is about the consistence of cream. (Hart. Trans. v. 310.) The French water once after shifting with a very strong lesive; they also much with recent cow and horse droppings, renewing these once a-month or oftener during summer, that there may be always abundance of soluble matter for the water to convey to their roots. (Nouveau Cours, &c. art. Orange.) M'Phail mentions a case in which very large orange-trees in the border of a conservatory looked sickly; when, on digging deep into the borders to examine the cause, he found the earth quite dry, and by afterwards continuing to water them regularly he recovered them. (G. Rem. 342.)

5925. Air. During the winter season, Miller observes, orange-trees require a large share of air when the weather is favorable; for nothing is more injurious to these trees than stifling them. The prevention of damp, Mean observes, is as essential to the perfection of the plants as the exclusion of cold. Where these trees are kept in old-fashioned opaque-roofed green-houses, these cautions as to air and damp deserve particular attention. Ayres says, the more air orange-trees have during the blossoming season, the more certain will they be of setting the fruit.

5926. Light. Many gardeners are of opinion that the orange tribe do not require so much light as other exotics, which may have arisen from the gloomy conservatories in which they used to be formerly kept during winter; for certainly to look at the orange-houses at Versailles and Kew, one would not conclude light to be a very essential requisite. But though these trees, like other evergreens, when in a state of inaction, will live with less light than evergreens or deciduous plants in a growing state, they always suffer for the want of it, which is indicated by the paleness of the leaves in spring, and by their falling off when set out in the open air and fully exposed to the influence of day. Whoever intends to grow the orange in any degree of perfection, should adopt houses, if not with glass on all sides, at least with glass fronts and roofs. When the plants are placed in the naked ground as standards, glass on all sides is highly desirable; for otherwise their leaves and shoots will all be turned to the south, and the north side of each tree will in a short time become naked and unsightly.

5927. Manner of growing the trees. All the species may either be grown as dwarfs in moderate-sized pots or boxes; as standards with stems from two to six feet high in large boxes; as standards planted in the naked ground; and either as dwarfs or standards planted and trained against a wall or trellis under glass. The two first modes are more adapted for ornament than producing crops of large fruit; for all the art of the gardener will never make plants grow as vigorously in boxes as in the free ground. Standards planted in the free ground or floor of the conservatory, combine both elegance and utility; as in a house properly constructed, they will make handsome heads, and produce abundant crops of fruit. The last mode, or that of planting against walls or trellises, is much the most certain way of having large crops. Every part of the plant above ground can thus be brought near the glass and equally exposed to the sun’s influence and that of the air and heat: they can be more readily pruned, and correctly trained, watered, and washed; and they occupy less room in proportion to the produce. The trees at Wood Hall, in West Lothian, some of those at Shipley, and at some places in Devonshire, are trained in this way. In a very few favorable situations in the South of England, as at Gerston and Woodville, in Devonshire, they are trained against walls in the open garden.

5928. Plans for orange-houses. These must naturally depend on the mode of growing. For plants in moderate-sized pots and boxes, a common green-house is the obvious habitation; for, being plants of ornament, they require merely the treatment of that department. The conservatories in Italy have generally opaque roofs, some of the more enlightened nobles of Lombardy have lately erected splendid constructions with glass roofs, in which they combine the culture of the citron tribe with other, large-growing exotics. (Fig. 530.)

5929. For trees in large boxes, a proportionably large and lofty house is requisite; it may be opaque, on the north side with a glass roof, front, and ends, of any convenient or desired length, width, and height. For one of moderate size, the height at the back wall may be fifteen feet, at front ten feet, and the width of the house fifteen feet. The floor may be either perfectly level, and the boxes placed on it, the largest behind, so as their tops may form a slope to the front glass, as in the conservatory of Prince Borghese.

at Rome; or if the trees are young, a stage may be erected for a few years, in order to raise the plants to the light: but if the trees are of a considerable size, the best way is to have square pits in the floor at regular distances, somewhat larger than each box, and in these to sink the boxes, covering them with
PRACTICE variations as these for best discussed "matted trees raised mon observes, of hoop, nieces, or necessarily stage like as in no other situation could the object of the spectator meet the foliage of the plants. Where the walk is in the middle, and a double row of trees on each side as at Monza, the effect in winter is truly magnificent and gratifying.

552. Where the trees are to be planted as standards in the borders or floor of the house, it is essentially requisite to the health and beauty of the plants that the building be glazed on all sides. (fig. 591.) Showers might be supplied in Loddige's manner; heat by steam or flues (fig. 592. a) and in winter, the bcds (b) might be covered with turf, strewn with daisies, violets, and primroses; these would come early into flower, and if the turf were kept very short about the roots of the flowering plants, and the trees in excellent condition, only those who have seen the first-rate, regularly planted, standard orange-groves of Nervi could form an idea of the effect, which, by contrast with the external winter, would be felt as luxuriant green if anticipated by real spring. (fig. 593.)

553. Where orange-trees are to be trained against the back wall or a trellis, under the glass, the forms adopted for common peach-houses or vineyards are perfectly suitable; but as by training close under the glass, as is done with vines, much of the beauty of the foliage would be lost, training on a trellis a few feet distant seen it and either shaded or preferable is preferred.

552. Plans for tubs, pots, and boxes. Unglazed pots of earthenware are preferable to glazed stone ware or China pots; the form need not be different from that in common use, and the size must depend on that of the plants. At Florence, where the largest and best garden-pots in Europe are made, the rim is placed at the outside of pots destined for oranges and ornamental plants, are often decorated with festoons of flowers or fruit, and lions' heads, or other ornaments; which some potters near London have begun to imitate.

553. Tubs may be of any size, and in these and in boxes, trees thrive better than in pots. One advantage of tubs is, that by unhooping them, the staves are instantly removed, and the roots examined and dressed, and by having a cooper at hand they are immediately replaced; thus saving much of the trouble necessarily incurred in shifting plants in pots or boxes.

554. Boxes. All boxes which are larger than the largest-sized pots, should be contrived to take to pieces, in order to examine the roots, or to shift into larger boxes. Square boxes held together by iron hoop, and taking to pieces on the principle of trees, are not most convenient for trees which do not require more than five or ten cubic feet of earth; and such as are used at the Tuilleries and by Mean (figs. 177 to 179) answer very well for plants requiring from ten to sixty cubic feet. Those of Mean contain sixty-four cubic feet of compost.

555. Proportioning the size of boxes to that of the plants. The general opinion of gardeners is in favor of small pots or boxes; and where the object is dwarf plants, or merely to preserve the trees without much increasing their size or regarding their fruit, they are the most proper. But where the object is luxuriance of growth and fruit, it does appear to us that the pots or boxes cannot be too large; unless, as Van Osten observes, it is meant to be asserted that plants grow larger in pots than in the free ground. It is, however, evident that such a view is not possible in small, or by depriving the plants of the outside of pots destined for oranges and ornamental plants, are often decorated with festoons of flowers or fruit, and lions' heads, or other ornaments; which some potters near London have begun to imitate.

556. Choice of sorts. Where the object is more ornament than fruit for the dessert, a selection may be made from the varieties of each species at pleasure; where the object is fruit for the dessert, the following sorts are to be preferred: the common, bloodystreighted, Bergamot, Maltese, sweet China, Seville, and Mandarin oranges; the common lemon, citron, and lime, and one or two plants of the shaddock. These include all the essential varieties of the orange tribe as far as respects fruit; variations in the leaves and mode of growth.

557. Choice of plants. For moderate-sized trees to be treated like green-house plants, such as are raised in this country or in the Parisian nurseries are preferable; but where the object is large handsome trees in boxes, standards in the free soil, or trained trees, then plants from Genoa or Malta are decidedly preferable; indeed, no plants fitting for the purpose of standards could be elsewhere procured. Miller is of this opinion, that by the quicker way of furnishing a green-house with large trees, is to make choice of such as are brought over every year in chests from Italy; for those which are raised from seeds in England will not grow so large in their stems under eighteen or twenty years, as those are when brought over; and although their heads are small when we receive them, yet in three years development, they become large heads, and produce fruit. But when the plants are purchased in London, at the Italian warehouses, without names, the greater number will be found to be of the shaddock and citron kinds; as the Italian gardeners find these sorts make stronger shoots and more showy plants, and therefore send a less number of the less luxuriant but more useful varieties. But the best way is to send an order, through a British merchant who has a correspondent at Genoa, for named sorts, ordering so many of each class, either from the table of Dr. Sickler (4880.) or the Synopsis of Gallego (30. p. 4881.)

558. Management in pots and boxes. The management of dwarf English or French plants in moderately-sized pots or boxes, for the green-house stage, consists in common green-house treatment. Being putted in the proper soil, the roots are to be annually examined before the growing season in spring, and when matted or diseased, trimmed off and reported, or shifted into larger pots at discretion. Henderson says, "The general management of the orange-trees from the middle of March till the Ist of October, may be discussed in a few words. I give the trees a good watering all over the leaves once a-week with the engine, except when they are in flower. Till the end of May this watering is given about 11 o'clock in the forenoon. After the end of May, I give them a good dashing over the leaves twice a-week with the engine, and now I do it in the evening. In very hot weather I repeat the engine-watering thrice a-week."
I never set the orange-trees out of doors during summer; for, from thirty-eight years' experience, I find it unsafe to do so. I maintain them, in the climate of Scotland. In hot weather I keep them in the back of the vineyard, under the shade of the grape-vine, which has the effect of keeping them, without the shade, where they are put, in the shade in sunny weather; they here grow freely, and keep a fine dark-green color. From the frequent watering over the leaves in summer, the pots require less water, but they must be carefully attended to. The first, in making their way, the water in the pots requires frequent shaking of the stems, to give them room for growing.

From October to March, I give them a gentle sprinkling over the leaves once in two or three weeks, but only in fresh weather, taking the opportunity of a mild day, when there is a little sun, and always in the forenoon." (Caled. Hort. Mem. iii. 303.)

5893. For the management of Italian plants, destined to grow large trees and produce crops of fruit in boxes or tubs, the treatment requires to be more particularly detailed.

5940. The following are Miller's directions:—Having furnished yourself with a parcel of trees, prepare a moderate hot-bed of manner's bark, in length and breadth according to the number of trees to be forced, this will have the effect of establishing the plants and giving the tubs a bottom, and the heat under the bottom part of the stem out of water, the better to draw and imbibe the moisture. In this situation they may remain two or three days, according to their plumpness when you received them; then take them out and cleanse the roots from all filth, cutting off broken or bruised roots, and all the small fibres which are quite dried by being in the hot-bed, and scrub the stems, to enable them afterwards with a cloth; then cut off the branches about six inches from the stem, and having prepared a quantity of good fresh earth, mixed with very rotten neat's dung, plant your trees therein, observing never to put them in too close, but big enough as for the first planting. Wrap the stems round with hay-bands from bottom to top to prevent the sun from drying their bark: plunge the pots in the bed, water well, settle them to earth, their roots, frequent repeating the same all over their heads and stems, being very careful not to over-water them before they have made good roots, and shade from the sun in the middle of the day. If you have given kindly they will have made strong shoots by the beginning of June; at which time stop them to obtain lateral branches to furnish their heads, harden them to admit their removal into the open ground in July; however, from the beginning of September, and during winter, water freely but moderately, allowing against frost. In the following spring clean the stems and leaves of the plants, top-dress the earth and mulch, with rotten cow-dung, round the edges of the pots, taking care that none touch the stems. Remove to a sheltered situation in the open air by the end of May. As the trees advance, stop strong irregular shoots that may come out later, and to form the branches into uniform, regular and free from weak trifling branches. The trees will require to be shifted and new-potted, every other year, in April. In performing the operation, have drawn the trees out of the pots, cut off all the roots round the outside of the ball of earth, and take away all mouldy roots; then with a sharp iron instrument, get out each of the old earth from between the root and the tree, till the tree into a large tub of water, for about a quarter of an hour, to soak the under part of the ball of earth, then clean the stems. Repot the trees, and water, letting them remain in the soil till they have taken root.

5941. The operation of shifting, when the plants become very large, is much facilitated by adopting boxes which admit of being taken to pieces, as already described; the balls of earth can thus be slid from one box to the other instead of being lifted out of the box. Where the boxes do not separate, the tree can be suspended by means of a rope that is passed through the trefoil and the eye of the tree; the root of the plant is then unrolled and turned over a pulley suspended from a triangle. This mode is recommended by Van Osten, while some French authors recommend a carriage-lever and rope. The tree and ball of earth are thus, by either mode, suspended in the air, the latter is examined, the roots pruned, &c., and this done, the same or a larger box is recommended, as the quantity of compost at the bottom, and into this the tree is lowered, and the sides filled with earth, &c. The worst thing attending this mode is the liability of injuring the bark of the stem by the noose of the suspending rope.

5942. Henderson shifts oranges only once in two years, and frequently after a longer interval. "I never shift any plant till the pot is very full of roots. In shifting the oranges, I always take as much of the exhausted mould away as I can; and, on account of the light and free nature of the compost used, it comes easily from among the roots. I make a sort of full Barton under the beginning of March. Then very carefully to draw out of the pots or tubs, pick as much of the old exhausted mould from the ball as you can, without injuring the roots. They should be shifted into the pots or tubs only one size larger, and some of the plants will perhaps do better if replaced into the same pots again. I lay the roots on a wash-stand; or, if I have any spare wash-stands put before them, I have a large pot or crockery or broken pot over the hole in the bottom of the pit, with the convex side down; then cover the bottom, above the piece laid over the hole, three quarters of an inch thick, with made from pit-coal, broken small, about the size of peas. This forms a drain, and prevents the earth from passing into the bottom of the pot. The compost should be of the same quality as described, and containing the same. I find the compost mould from getting down amongst the char, and lets the water pass off freely from the roots of the plants. The bottoms of the pots being prepared in this way, put in a little of the compost; then into the roots; if they are a big compost, contain the roots, it will serve to keep a little of the mould between the side of the pot and the roots. The plants may be set into the peach-house or the vineyard, and some into the green-house, which will give a longer succession of their flowers. The orange-trees that are placed in the vineyard or peach-house, if there be any fire-heats used at the time, must be watered as soon as put in; but those put into the green-house where there is little heat, may stand a day without getting any. After that space they may get a moderate watering; and this may be repeated once a-week till the weather become warm, when they will require it oftener. The plants will be pruned in the following spring, according to the degree of heat kept in the house." (Caled. Hort. Mem. iii. 304.)

5943. Renovating old trees in pots or boxes. Where orange-trees have been ill managed, and their heads become ragged and decayed, Miller directs to restore them by cutting off the greatest part of their heads by March; drawing them out of the pots or tubs, and shaking off the earth from their roots; then cutting away all small fibres and mouldy roots; and next soaking and cleaning their roots, stems, and branches, planting them in good earth, plunging them in a hot-bed, and treating them as directed for trees received from abroad.

5944. Management of the citron tribe as standards. Prepare foreign plants as directed above, and instead of planting in pots, plant in the border or floor. This must have been laid dry by proper drains, and if on a wet sub-soil, floored, to prevent the trees from penetrating into it. On this, lay the sort of earth, or compost, most approved of, to the thickness of three or four feet; care having been taken in constructing the house, the same as above, cover it with a layer of cooled manure, if the house is long, or of sand, or of any dry hard material, or of something which may be supported on pillars or piers, so as the compost may extend under them, and ten or twelve feet without the house, according to circumstances. Plant the trees either in squares, or better in quincunx, allowing six or eight feet between the trees, which will give thirty-six to forty square feet for each plant. This distance will suffice for several years, and afterwards every other tree can be taken out. After planting,
which should be finished in April, water at the root, and morning and evening sprinkle a little over the tops to assist in causing them to break freely. Apply fires, and keep the house close night and day, with a moist heat of from 55° to 60° till the plants have made shoots of three or four inches; then begin to give a little air, gradually increasing it, but still keep a little air coming in through the shutters. The heat is then off to harden and color the shoots and leaves. It will be necessary to attend to the above directions annually, for three or four years, in the growing season, in order to procure as much wood in a short time as possible. Keeping the heads open and regular, with the consequent growth of fruit, is the only advantage they have.

5945. On walls and espaliers. Prepare the plants and the border as before, and plant about ten or twelve feet distance, allowing a larger space for the citron, lemon, and shaddock, than for the common orange, as the former grow faster and more luxuriantly. In the growing season, observe the directions already given, cultivating as the aid of pruning. Only. The top-dresses should be removed.

5946. Pruning. The French pay great attention to this part of the culture of the orange tribe; and, indeed, display greater art in pruning every sort of tree, than the British. They have their winter taille, and their ebourgeonnement, or summer pruning, of the orange-groves, done every year, and receive a very elaborate pruning every sixth or eighth year. The object of this pruning is to keep the head proportionate to the capacity of the box containing the roots. The heads of these trees, notwithstanding the annual pruning, become too large and show indications of becoming too full, and want a compactness every year; and therefore are thinned out to within an inch or two of the old wood, and the tree, thus almost completely deprived of leaves, does not produce blossoms during the two next years: it pushes, however, vigorous shoots, which are trained to form a bushy well finished head of the same shape and size. Such has been the practice of the late M. Pétion, who was head gardener at Versailles for forty years. The form of the heads of the trees at Versailles is that of a cylinder, spreading out at top, of which the height is greater than the breadth; those in other places are ovate, globular, or mushroom-shaped, and some are even square and triangular. (See Fau. Osten, cxi.)

5947. Which orange grove is the most productive in England, does not differ, in general, from that given to any green-house-tree or shrub; and the consequence is, handsome bushes or trees, with the blossoms and fruit on the surface of the foliage. But when the orange-tree is cultivated for fruit, whether as standards or against walls, the branches ought to be kept thin, like those of other fruit-trees, so as to admit the sun, air, and water, to every part of the tree. It is the interest of the fruit, not the centre to the extremities. This is readily effected where the trees are flat-trained, which, where fruit is the object, is a great argument in favor of that mode of culture.

5948. In pruning, with a view to fruit, it must be considered, that the most useful blossoms of most sorts of orange trees are produced in the former, and flowering period, or the wood of the current year; and hence, the grand object of the pruner ought to be to encourage the production of young wood in every part of the tree; by cutting out naked wood, and shortening vigorous shoots where wood is wanting. A powerful con- pulsion is thereby brought to the expansion of the parts of the tree, where the wood is not observed, is only to be done in standards, by keeping the trees open, or by flat training. There are also blossoms produced by various sorts of citrus, in tufts, directly from the axil of the leaves of the preceding year; these expand earlier than the others, but generally drop off in plants kept under cover by the old price of greenhouses, which are, however, the most productive wood, and shorten very strong branches to keep the trees in proper shape. After the fruit is set, it ought to be thinned, seldom leaving more than one on a peduncle. In France they thin the flowers, which, by that means, they are enabled to use for distillation. The thinned fruit is used in confectionary. Mean observed, "In regard to the necessity of thinning the fruit, lest the trees should exhaust themselves, it appears to me to depend on the state of the trees: if they are flourishing, I never observed that it was at all required, either here or at Bromley Hill, where the orange-trees belonging to the Right Hon. H. Addington are very vigorous, and covered with fruit." The large, flat, yellowish, and red oranges are about the size of green-gage plums, and never leave two fruit together. Will standard trees, pruned with a view to fruit, be equally beautiful with the compact geometrically-headed trees of Paris, and the old conservator at Versailles? Prune, or let them alone for fruit, and answer for yourselves. I think the French prefer a flat-trained tree, for the sake of making better: it is more open for the sun, and the air will not think so. The two beauties, or effects, are of different kinds; the latter has utility to recommend it; the former, associations of the pomp and formal grandeur of past times. Quintiniey, and other French authors, direct the wounds or sections made in pruning orange-trees, to be covered with a combination of tar and pitch, which deserves to be attended to, as the growth of the bark is otherwise very slow over wounds in these trees. 5949. Manure. About Genoa, the best cultivated orange-groves are manured annually. In France and this country, the best practitioners stir the surface and apply a dressing of rich compost when the trees begin to grow, generally in April or May. Ayres top-dresses in June.

5950. Gathering the fruit. In the Italian gardens, and those at Hiers in France, where the fruit of the orange is raised for sale, it is gathered every year, generally in May. If not then gathered, it will hang on the tree produced in the two years before, and fall at the first frost; and when the tree is thus stripped of its leaves, it becomes somewhat shrivelled, and if then gathered is found almost void of juice. But as the new fruit begins to arrive at maturity, the juice begins to return to the old fruit; so that both old and new crops are in this condition when gathered in the following way: The fruit is gathered from the main on the tree three years, and being then gathered, has a peculiar subacid sweetness and flavor, and is sold at a very high price to connoisseurs at Milan, Turin, and other places. The lemon differs from the orange in that it ripens irregularly, and drops off when ripe. It is therefore gathered at almost every season of the year. To keep the fruit long, generally requires fifteen months to ripen its fruit, and hence, both green and ripe fruit are together on the tree. Some authors assert, that the leaves remain on the same season with the fruit; but Quintiniey says, "On a vigorous plant they will remain three or four years at the least; but in those which have been cultivated more than seven years on one and the same head, bearing for the table in this country, the fruit should not be pulled with the hand, but carefully cut off with a few leaves attached, and thus garnished, sent to the dessert. By allowing them to hang two years, the trees will at all times have green and yellow fruit, which, in connexion with their shining green leaves and fragrant flowers, early, fresh, and full, in such a house as we have hinted at (5920. and fig. 221.), is one of the most splendid of horticultural scenes.

5951. Insects and diseases. The chief insects injurious to the citrus tribe, are the coccus and red spider; both of which have been destroyed by introducing the ladybird into the houses, where they are kept. When he top-dresses his plants, applies a copious washing with the engine; then shuts up the house close for three or four hours, which produces a strong heat, as high as 70°, which effects the destruction of the red spider; while the stems and leaves are wiped with a wet sponge to remove other insects and dirt. (Hort. Trans. ii. 238.) Henderson destroys the aphids by fumigation; the red spider by sprinkling and dashings with water; the coccus, by laying on the leaves with a brush some black soap dissolved in water, or by washing and dusting the leaves with sulphur; and the only remaining insect which infests the orange, the thrips, he destroys with water. (Calcut. Hort. Mem. 315.)

5952. The pomegranate is a low deciduous tree, rising fifteen or twenty feet high, thickly clothed with twiggy branches, some of which are armed with sharp thorns. The leaves are long and narrow, of a light shining green with red veins. The flowers are produced at the ends of the branches, in the shoots of the same year, single or three or four together; frequently one of the largest terminates the branch, and immediately under that are two or three smaller buds, which continue a succession of flowers for some months, generally from June to September. The calyx is very thick and fleshy, and of a fine red color; the petals are scarlet. The fruit is a berry covered with a hard coriaceous rind, and beautifully crowned with the tube of the calyx, which is sharply toothed, and remains even after the fruit is ripe, contributing greatly to its singular and beautiful appearance.

The fruit ripens in October, and, in a green-house, will hang on the trees till the spring or summer following. It is a native of most parts of the south of Europe and of China. In Languedoc, and some parts of Italy, it is used as a hedge plant. It was cultivated in England in 1596, by Gerrard; but though it grows very well in the open air, it seldom ripens its fruit so as to render them worth any thing. It used formerly to be kept in boxes, and housed like the orange-tree, which is still the practice near Paris and in the Netherlands. Some of the orange and pomegranate trees in the orangery at Versailles, Riso informs us, are believed to be between two and three hundred years old.

5953. Use. The fruit having an acid pulp is very refreshing, and is eaten like the orange; its singular and beautiful appearance contributes to the variety of the dessert. It is used medicinally in fevers and inflammatory disorders; being powerfully acid and astringent.

5954. Varieties. The Paris nurseries propagate the following sorts: those marked thus (*) may be had in the London nurseries.

<table>
<thead>
<tr>
<th align="center">The wild, or very acid-fruit</th>
<th align="center">The semi-double, and double red and white</th>
<th align="center">The prolific, in which a shoot proceeds from the middle of the flower.</th>
</tr>
</thead>
<tbody>
<tr>
<td align="center">The subacid-fruit, or cultivated *</td>
<td align="center">The yellow-flowered *</td>
<td align="center">The variegated-flowered</td>
</tr>
</tbody>
</table>

5955. Propagation. The single-flowering sorts may be raised from seed, and all the varieties by cuttings, suckers, or layers, or by inoculation or grafting on the wild sort. The last is considered much the best mode where fruit is the object; and the next best is by layers, but the common mode is by suckers, which these plants send up abundantly. Inoculated plants, both of the single and double sorts, may be procured from Genoa; and this is the most desirable plan where the plant is to be cultivated for its fruit.

5956. Culture. The directions given for raising and cultivating the orange-tree may be considered as equally applicable to the pomegranate, which, with the olive, was formerly the common companion of these trees in conservatories. Miller has observed, "that both the single and double pomegranate are hardly enough to resist our most severe winters in the open air; and that if planted against walls, the former will often produce fruit, which ripen tolerably well in warm seasons, but ripening late, are seldom well tasted." Where it is to be grown for fruit, therefore, either the standard or flat trained mode, under glass, is recommended for oranges, should be adopted. A few trees may be introduced along with those of the citrus tribe.

Soil. — Miller recommends a strong rich soil, in which he says, "they flower much better, and produce more fruit than if planted on dry ground." In regard both to soil and mode of growth, the pomegranate bears a close resemblance to the hawthorn.

5957. Pruning and training. As already mentioned, the flowers of this tree always proceed from the extremity of the branches produced the same year, hence all weak branches of the former year should be cut out, and the stronger shortened, in order to obtain new shoots in every part of the tree. When the trees are trained against a wall, the shoots having small leaves, may be laid in four or five inches asunder. The season for the winter pruning, Miller says, is about Michaelmas; for if left till spring before they are pruned, they seldom put out their shoots so early. In summer they require no other dressing than pruning off fore-right and over vigorous shoots, as it is the middling only which are fruitful. In a warm situation Miller obtained a great quantity of fruit from trained trees; which, though not very well flavored, were of full magnitude, and made a very handsome appearance on the trees. The double and other varieties, cultivated for the sake of their flowers, should be pruned, whether in boxes or against walls, on the same principle.

5958. The olive is a low branchy evergreen tree, rising from twenty to thirty feet, with stiff, narrow, bluish-green leaves. The flowers are produced in small axillary bunches from wood of the former year, and appear in June, July, and August. The fruit is a berried drupe of an oblong spheroidal form, hardish thick flesh, of a yellowish-green color, but turning black when ripe. The tree is supposed to be originally from Greece; but it is now naturalised in the south of France, Italy, and Spain, where it has been extensively cultivated for an unknown length of time, for the oil expressed from its fruit. The tree attains an incredible age. Near Terni, in the vale of the cascade of Marmora, is a plantation above two miles in extent, of very old trees, and supposed to be the same plants mentioned by Pliny, as growing there in the first century. It appears to have been cultivated in the botanic garden of Oxford, in 1648, and is generally treated as a green-house plant. With protection from severe frost, Miller says, "it may be main-
tained against a wall in the latitude of London." In Devonshire, some trees have stood the open air for many years; but the fruit does not arrive at maturity. Some trees planted against a warm wall at Camden House, near Kensington, succeeded so as in 1719 to produce fruit fit for picking.

5959. Use. At the dessert, and frequently, also, during dinner, unripe olives appear as a pickle; which, though to those who taste it for the first time, it appears somewhat harsh, yet it soon becomes extremely grateful; and is said to promote digestion and create an appetite. Pickled olives are prepared by steeping in an alkaline lessive, to extract a part of their bitter; they are next washed in pure water, and afterwards preserved in salt and water, to which an aromatic, as fennel, &c. is sometimes added. The ripe olive, pressed and washed with hot water, furnishes, when skimmed, the well known condiment and corrective, salad-oil, employed both in food and medicine. It may be considered as the butter of Italy and Spain.

5960. Varieties. In the olive-countries these are nearly as numerous as the sorts of the grape and fig. The French (N. Cours, &c. in loco) describe between thirty and forty sorts. The following are grown in English nurseries:—

The common | Large-leaved | Broad-leaved | Iron-colored | Twisted-leaved | Box-leaved.

5961. Propagation. By seeds, cuttings, layers, suckers, and inoculation. The last mode is adopted where the culture of the olive is conducted with care; but the oleaeae, or olive-plantations, are generally furnished from suckers, which arises from the roots of old trees. In England, as a green-house plant, it is raised from cuttings; but where it is intended to grow a few trees in the forcing-department, for the sake of their fruit, we would recommend procuring strong plants from Genoa; these will produce fruit in three or four years, but the others not for an unknown length of time.

5962. Culture. Some plants used formerly to be received by the Italian merchants along with their imports of orange-trees, and were planted, like them, in pots or boxes; but in order to grow the tree for fruit, the modes to be adopted are either planting as standards in the area, or training on a wall, as recommended in the case of pomegranates. If a house is not devoted to this fruit, one might be appropriated for it and the pomegranate; giving each their respective soils, and recollecting that the olive will not bear a very high degree of heat.

5963. Soil. The olive will grow luxuriantly in a strong clayey richly manured soil, but will not prove near so agreeable in a light, nor in a light and clearaceous, schistous, sandy, or rocky situation; which ought to be imitated in some degree in the composition prepared for the area or border of the olive-house.

5964. Temperature. That suitable for the orange will agree with the olive; but it cannot bear so high a degree of heat as that plant, never being found in Africa south of Atlas, nor in the East or West Indies. It is also easily affected by cold, but not more so than the orange.

5965. Pruning. The object here is to have a regular distribution of wood of the former year, from the axils of the leaves of which, the flowers spring out. When shoots of three or more years are shortened for this purpose, they do not produce blossoms; but wood of the proceeding or current year may be shortened, and the shoots proceeding from them will produce blossoms in due course. Ringing, to induce fruitfulness, was practised on the olive so early as the seventeenth century. (Bosc, in N. Cours, &c. art. Olive.)

Subsect. 4. Indian Fig, or Prickly Pear. — Cactus opuntia, L. (Knor. Thes. 1. t. F. a.) Icos. Monog. L. and Cacti, J. Raquette, Fr.

5966. The genus cactus consists of succulent plants, permanent in duration, singular and various in structure, generally without leaves, and having the stem or branches jointed, and for the most part armed with spines and bristles. The joints or branches of the C. opuntia are ovate, compressed, and have very small cadaverous leaves coming out in knots on their surface, and accompanied by four short bristy spines. The branches spread near to, or trail on the ground. The flowers come out on the upper edges of the branches in June and July. The fruit is in the form of a fig or pear, with clusters of small spines on the skin, which encloses a fleshy pulp of a red or purple color, and agreeable subacid flavor. It is a native of Virginia and Barbary, but is now naturalised in the south of India, being found on the rocks at Terracina and Gaeta. It was cultivated in England by Gerrard, in 1596, in the open air, but without bearing fruit. It was cultivated in the stove by Justice at Crichton near Edinburgh, in 1750, and ripened its fruit. Miller says, "it will live abroad in England in a warm situation and dry soil; but in severe winters will be destroyed if not protected from frost."

5967. Use. The fruit is sent to the dessert in the West Indies; and might add to the variety of exotic fruits in this country. Braddock observes (Hort. Trans. ii. 259.), that in countries where the fruit abounds, it is considered very wholesome, and though the taste of it is not agreeable to all persons till after they have eaten of it several times, yet they soon become very fond of it.

5968. Sorts. There are several species of that division of the genus cactus, called prickly pears or figs, which produce edible fruit in their native countries, as the great Indian fig, or upright prickly pear, (C. foetida) (Plant. grass 138); oblong Indian fig (C. foetida Indica) (Reich, vol. ii. 470.); Barbadoes gooseberry (C. peruviana) (Dill. cit. t. 257. f. 394.); the C. opuntia is deemed the most hardy, and by consequence the easiest to fruit in Britain; but there can be no doubt that the other sorts might also be brought to mature their fruit with very little expense or trouble. They are at present kept in dry-stoves for the sake of curiosity.

5969. Propagation and culture. All the above sorts may be propagated from seed or cuttings; the latter mode is most common. Cut off the branches at the joints, in July, or after the plants have done flowering, and let them dry for a fortnight, that the wounded part may be healed over; then plant in small pots, and plunge in the bark-bed, or in a moderate hot-bed, watering sparingly, giving air to avoid damp, and shading from the midday sun.

5970. Soil. Miller recommends the following: one third of light fresh earth from a pasture; a third
part of sea-sand; and the other part, one half rotten tan, and half lime rubbish. These are to be mixed and laid in a heap, three or four months before using, turning it over once a month; then pass it through a rough screen, but do not sift it fine; reserving some of the small stones and rubbish to lay at the bottom of the pots, in order to keep an open passage for the moisture to drain off. The Barbadoes gooseberry requires less lime-rubbish and more of vegetable earth.

375. Temperatures. All the sorts, excepting the prickly pear, require the temperature of a dry-stove in winter, and an increased degree of heat, say 80° or 90° in summer, when it is intended they should produce fruit. They may either be planted in large boxes, filled with the soil above described, with a portion of vegetable mould added; or in borders, to be trained on a wall or trellis near the light. In either case, they will be likely to bear fruit in the summer, whilst in a growing state, with heat at bottom and top, air, light, and some moisture, they will thrive abundantly, and produce fruit certainly not of exquisite flavor, but agreeable and singular, and worthy of being added to the British dessert.

372. Culture of the prickly pear in the open air.Bradstock having eaten, with pleasure, of this fruit in Virginia, was desirous of cultivating it here. He recollected that the plant in its wild state delighted in a dry soil, amongst rocks, near the skirts of the sunny sides of the forests; and having heard that it would stand the open air in this country, he planted it in the compost described below, placed in a sheltered place, and let it have the sun. "The first plant that I turned out has lived in the open ground of this country for six or seven years, during which period it has endured one succeeding hard winter, and several trying springs; and in all, except the two first years, it has never failed to ripen its fruit and seeds, so that it may be now considered decidedly acclimated. The compost used by me for growing the Opuntia ficus-indica is the following: one half is carbone of lime, for which limce-rubbish from old buildings will answer; the remaining half consists of equal portions of London clay and peat-earth, having the acid neutralised by barilla: these are intimately blended and sifted. One square yard of this compost I conceive to be sufficient for one plant, which must be placed in the middle of a small artificial hillock, raised eighteen inches above the surface of the ground, which ground should be rendered perfectly dry, if not naturally so, by under-draining. Neither the leaves, flowers, nor fruit should ever be suffered to touch the ground, but they should, as constantly as they are produced, be kept from the earth by placing stones, pebbles, flints, or bricks under them, in imitation of artificial rock-work." (Hort. Trans. 288.)

5973. The torch-thistle, or upright cactus, of which there are four species which bear edible fruit, and the strawberry-pear (C. triangularis), the poire de chardon of the French, may also be cultivated as fruit-bearing stove plants, in the same way as recommended for the Indian fig.

Sect. III. Exotic Fruits little known, some of which merit Cultivation for their Excellence or Rarity.

3774. The introduction and cultivation of new exotic fruits may be considered as a very rational and entertaining object, for such as have the means, the time, and a taste for gardening. It seems to deserve the particular attention of retired persons of solitary habits, aged or inactive, by presenting an end to be attained; it may serve as a gentle stimulus to such as, from indolence or bilious complaints, are apt to sink into a state of torpid unenjoyed existence. A few of the plants, which we shall here enumerate, have been cultivated so as to produce fruit in this country, as the granadilla, lee-chee, loquat, banana, &c.; most of the others have hitherto served only to increase the variety of our stove or green-house plants.

3775. The akee-tree is the Blighia Sapida, H. K. (Ann. Bot. 2. t. 16, 17.) Oct. Monog. L. and Sapindii, J. (fig. 523.) It is a tree rising from twenty to twenty-five feet in height, with numerous, large, and alternate pinnate leaves, like those of the common ash. The flowers are small, white, on axillary racemes. The fruit is a pome, reddish or yellow; about the size of a goose’s egg, with a pulp of a grateful subacid flavor; and in the West Indies esteemed very wholesome and nourishing. It is a native of Guinea, and was introduced in Jamaica in 1778, and from thence brought this country in 1793.

3776. Propagation and culture. It may be propagated from seeds, cuttings, or layers; but as the former mode would prolong the period of culture for fruit, and the latter produce but weak plants, the better plan would be to order a few trees to be inoculated in Jamaica, and then sent over in tubs; these might be treated as directed for orange-trees (5939), and then planted in a border of rich earth, submitted to a Jamaica climate, and flat-trained near the glass. By such treatment, there can be no doubt the akee-tree would in a few years produce fruit as readily as the orange.

3777. The alligator, or avocado pear, is the Laurus Persea, L. (Pluk. Alm. t. 267. t. 1.) Ensean. Monog. L. and Laurinae, B. P. It is a stove tree which, in the West Indies, grows to the height of thirty feet or upwards, with a trunk as large as that of our common apple-tree. The leaves are like those of laurel, of a deep-green. The flowers are produced towards the extremities of the branches. The fruit is the size of one of our biggest pears, and is held in great esteem in the West Indies; the pulp is of a pretty firm consistence, and has a delicate rich flavor; it gains upon the palate of most persons, and becomes so agreeable even to those who cannot like it at first; but it is so rich and mild, that most people make use of some spice or pungent substance, to give it a piquancy; and for this purpose some make use of wine, some of lime-juice, but most of pepper and salt. Miller, from whom the above account is extracted, cultivated it in 1739.

3778. Propagation and culture. Miller gives directions for raising the tree from seeds, which, he says, may be sown three or four months before using, turning it over once a month; then pass it through a rough screen, but do not sift it fine, reserving some of the small stones and rubbish to lay at the bottom of the pots, in order to keep an open passage for the moisture to drain off. The Barbadoes gooseberry requires less lime-rubbish and more of vegetable earth.

3779. Temperature. All the sorts, excepting the prickly pear, require the temperature of a dry-stove in winter, and an increased degree of heat, say 80° or 90° in summer, when it is intended they should produce fruit. They may either be planted in large boxes, filled with the soil above described, with a portion of vegetable mould added; or in borders, to be trained on a wall or trellis near the light. In either case, they will be likely to bear fruit in the summer, whilst in a growing state, with heat at bottom and top, air, light, and some moisture, they will thrive abundantly, and produce fruit certainly not of exquisite flavor, but agreeable and singular, and worthy of being added to the British dessert.
a few stocks to be inoculated from bearing trees. These being properly eased and packed, would arrive as safe as orange-trees usually do; might be treated like them when unpacked; and planted in a border of strong rich soil, to be trained on a trellis or wall near the glass. After the plants were established, horizontal training and ringling, accompanied by a Jamaica temperature, would soon produce fruit.

5979. The anchovy-pear is the Grrias cariciflora, L. (Sloane. Hist. 2. t. 217. f. 1. 2.) Polygan. Monog. L. and Guttiéf. J. (Ag. 326.) It is a stave tree, frequently growing to the height of fifty feet in the West Indies, where it is a native. The leaves are oblong, and two or three feet long. The flowers numerous on short peduncles, large and whitish. The drupe is ovate, and crowned like the pomegranate, about the same hardiness and shape and of an alligator's egg; it is pickled, and eaten like the East Indian mango, which it greatly resembles in taste. It grows generally in low moist bottoms, or shallow water, and has a most elegant appearance. Introduced here from Jamaica in 1768.

5880. Propagation and culture. It is very readily propagated from the stones, and the plants must be kept in a moist heat. To grow it for fruit, plant in a border, and train horizontally near the light, as directed for the avocado-pear. (3973.)

5981. The durian is the Durio Zibethina, L. (Rumph., Amb, p. 99) Polygandelph. Polygan. L. and Aapparies, J. (Ag. 252.) This is a lofty East Indian tree, with leaves resembling those of the cherry, and large bunches of flowers coming out below the leaves, of a pale-yellow color. The fruit is the size of a man's head, roundish or oblong; resembling in some degree a rolled-up hedgehog, with a hard bark or rind; the fleshly part of the fruit is of a creamy substance, and of a delicate taste; but of an unpleasant heavy smell, somewhat resembling that of rotten onions; and the smell of the breath of those who eat it is infernal. The fruit is also in a high degree; but when once a person has accustomed himself to this fruit, he generally considers it the most excellent of all. Rumphius says, it is by much the most excellent fruit of India. The tree has not yet been introduced; but if a few fruit or plants were sent for from the Calcutta garden, and submitted to the general plan of culture for trees difficult to fruit, there can be no doubt of success.

5982. The white guava is the Psidium pyriferum, L. (Rumph. amb. t. 57.) Icos. Monog. L. and Myrtil. J. (Ag. 532.) It is a West Indian tree, growing to the height of seven, eight, or twelve feet, with numerous branches and blunt, entire, smooth leaves, two or three inches long; the flowers are in solitary peduncles and sweet-scenting; fruit bigger than a hen's egg, roundish or oblong, smooth, yellow; the rind thin, brittle, and yellow; pulp firm, full of bony seeds, flesh-colored, sweet, aromatic, and pleasant. It is eaten with avidity both by West Indians and Europeans, raw in the dessert, and preserved with sugar. It has been grown here as a stave plant since 1858; it is propagated by seeds from ripe fruits brought over; and to be fruited should be treated as directed for other similar fruit-trees already mentioned.

5983. The red guava (P. penniferum) has a beautiful fruit, crowned like a pomegranate; but is not so agreeable to eat as the other.

5984. Cattley's guava. P. Cattleyanum. A new species introduced from China by Messrs. Barr and Brooks, nurserymen, and fruited by W. Cattley, F. H. S., in 1820. The plant resembles the other species in general habit and appearance; but the fruit is larger, nearly spherical, of a fine deep claret color, growing in the axilla of the leaves; the skin has much the consistence of that of a ripe fig, but is thinner; the interior is a soft fleshy pulp, parfusish-red next the skin, but becoming paler towards the middle, and at the centre it is quite white; it is juicy, and in consistence is much like a strawberry, to which it bears some resemblance in flavor. (Hort. Trans., iv. pl. x. 315.)

5985. The jam-sauce, or rose-apple, is the Eugenia Jamboos, L. (Bot. Mag. 1866.) Icos. Monog. L. and Myrtil. J. (Ag. 527.) It is a branchy tree, rising from twenty to thirty feet high, with long narrow leaves not unlike those of the peach. The flowers come out in terminal bunches in July, are of a greenish-yellow color, and succeeded by fruit about the size of a hen's egg, white, red, or rose-colored, with the flavor of a ripe apricot, and ripening from September to December. It is a native of the East Indies, and was cultivated here by Miller, in 1768. There are several varieties of this tree differing in the size and color of the fruit. That with white fruit has been cultivated by Professor Thouin in the Jardin du Roi at Paris. This horticulturist endeavored to harden the tree by exposing it annually to the open air during the two hottest months of the year; but, after persisting in this mode of cultivation for several years, and finding the leaves and part of the shoots die off annually, in consequence of the cold while exposed, he at last had recourse to a hot and moist atmosphere, and was successful. (Hort. Trans. 1. App.) Cattley has a plant which regularly yields him abundance of fruit. (Hort. Trans. v. 112.)

5886. The Malay apple is another species of Eugenia (E. Malacensis), (Bot. Rep. 438.) The tree resembles the former, but has broader leaves. The fruit is ovate, an inch and a half in diameter, fleshy, very sweet-smelling, like the rose, agreeable to the taste, smell, and sight, and esteemed wholesome. It is common in most of the islands in the South Sea, and was cultivated by Miller in 1768.

5987. The bastard guava (E. Pseudo-Psidium) and the Cayenne cherry (E. colonfolia) produce
edible fruits, held in considerable esteem in the West Indies, and with the Malay apple appear to deserve culture in this country. (See Miller's Dict.)

5988. The custard-apple (Anona reticulata), elligator-apple (A. palustris), sweet-apple (A. squamosa), and sour-apple (A. muricata), are esteemed West Indian fruits; the Cherrymoyer (A. lirpetala), the Cherimolia of some botanists, is the fruit most prized by the natives of Brazil and Peru. All these plants are already in our stoves, and might easily be cultivated as fruit-trees.

5989. The mammee-tree (Mammee americana, L.) Polyan. Monog. L. and Gutierrez, J. is a tall handsome tree, with oval, shining, leathery leaves, and one-flowered peduncles, producing sweet white flowers an inch and a half in diameter, succeeded by roundish fruit, about the size of an egg, and in pulp and taste not unlike the apricot. It is eaten raw alone, or in slices with wine and sugar, or preserved in sugar. It is a native of the Caribbean Islands, and was cultivated in 1730 by Miller.

5990. Propagation and culture. It may be raised from the stones or seeds, and treated like other stone fruit-trees. It has been cultivated by Knight, who found it rather im- patient of a very high temperature. (Hort. Trans. iii. 464.)

5991. The lee-chee and long-yen. The lee-chee is the Dimocarpus Longchen, (Lam. iii. i. 936) Octan. Monog. L. and Sapindi, J. It is a stove tree, with compound leaves, not unlike those of the common ash-tree; a native of China, and introduced in 1786. The fruit is a berry of a red color when ripe, except in one variety which remains green; it is much esteemed by Europeans.

5992. The long-yen or lee-chee (J. Buch. Long.). The tree resembles the former, but the fruit is not so large, and is of a light brown color. "In both species the pulp of the fruit is surrounded with a tough, thin, leathery coat; it is a colorless, semi-transparent substance; in the centre of which is a dark brown seed of different sizes in the different varieties. The flavor of the pulp is slightly sweet, sub-acid, and particularly pleasant to the taste in a warm climate. The fruit of the lee-chee, dried either in the sun or by fire-heat, is frequently brought to England from China. In this state the pulp is shrivelled and reduced within the coat, or shell, to half its usual size, and has a rich and sweet taste, if it has been well preserved. The fruit of the long-yen has been raised by John Knight, Esq. of Lee Castle, in a hot stove, erected for the purpose of growing tropical fruits; and a bunch was presented to him by the Hort. Society, in September, 1816, supposed to be the only one ever produced in Europe, and which persons well acquainted with the long-yen in its native places of growth, pronounced quite as good as those grown within or near the tropics." (Hort. Trans. iii. 465.)

5993. Propagation and culture. Both species may be raised from seeds or layers, and the plants may be afterwards placed in a bed or area of rich soil, and trained or spread out near the glass. The temperature should never be under that of the pine-apple.

5994. The loquat is the Mesplius japonica, (L. Vent. Main. 19, and Hort. Trans. iii. tab. 11.) Eriobotrya japonica, Lam. Icon. Di-Plant. L. and Rosaceæ, J. (fig. 32.) In a wild state it is a lofty tree with thick knobbed branches, and tomentose spray or bracts; the leaves are narrow, a span long, bright-green and cinereous tomentose below. The flowers come in spikes at the ends of the shoots in October and November. The fruit is a five-celled pome, about the size of a gooseberry, and in taste approaching to that of the apple. It ripens in May and June. It is a native of Japan, and was introduced in 1787 to Kew-gardens, where, as well as in some other places in this country, it is much grown. It is excellent for dessert.

5995. Propagation and culture. It may be raised from seeds, or continued by cuttings or layers; but the best method, when it is intended to produce fruit, is to graft it on any other species of mesplius. It is considered as a frame or half-hardy tree; but, to ripen its fruit with flavor, should have the temperature of the stove, in which, planted in a border of rich soil, it will add to the variety of the dessert. Sir Joseph Banks (Hort. Trans. i.) considers the fruit as equally good with that of the mango. Lord Bagot, who has fruited the plant in a very superior manner for several years at Blithfield, gives the following outline of his practice: "The plan I have usually followed has been to give it a winter (out of doors) during the months of July, August, and September, and about the middle of October to replace it in a very warm situation in the tan. This summer, however, I was obliged to alter my mode; for, just at the moment when I was going to put it out for its winter, it became covered with at least twenty bunches of the finest florets or apples: I was therefore obliged to let it remain where it was. The present year's treatment, therefore, is an exception to the former practice; under that, it usually breaks into flower about the end of December, and the fruit becomes ripe in March or April. The last time my plant was in fruit, Sir William Coke, who had resided many years in Ceylon, where he is at present, was with me at Blithfield; he told me he had been in the constant habit of eating very large quantities of the fruit daily in that island, but that he had never tasted any so good, and with so much flavor, as those produced in my garden."

5996. The mango-tree (Mangifera indica, L. Bot. Rep. 425.) Pent. Monog. L. and Terebinacea, J. (fig. 629.) is a large spreading tree, like the walnut, with lanceolate shining green leaves, seven or eight inches long, having a sweet resinous smell; the flowers are white, growing in bunches at the extremity of the branches. The fruit a drupe, large, kidney-shaped, covered with a smooth, soft, thick, brown pale-green, smooth, or half-red skin, and containing an ovate, woody, fibrous, compressed nut or stone,
within which is an ovate kernel, soft and pulpy, like a damascene plum. "When ripe, it is replete with a fine agreeable juice; it eats like an apple, but is more juicy, and some are as big as a man's fist. It is esteemed a very valuable fruit, and is often raised very richly; the people of India: generally in the beds to eat little or other fruit in the hot months. In Europe we have only the unripe fruit brought over in pickled." (Martyn, in Miller's Dict.) It is a native of the East Indies, and was introduced in 1630; but has not yet been cultivated for its fruit. According to Governor Raffles, forty varie-

5967. Propagation and culture. It may be increased by cuttings like the gardenia, which it somewhat resembles in habit, or from nuts; but as the vegetative quality of these does not seem to admit of long preservation, they must be enclosed in water, and otherwise managed (1802), to preserve it. It is a tree rising near twenty feet high, and is often cut to prop up the tan-pat; and he recommends the dry stove, a temperate heat, and light kitchen-garden earth. This tree seems particularly desirable for its fruit, both on account of its quality, and the plants not requiring so much heat as most of the other untried Indian fruits. It is not so much raised in plantations from fruit as in the following March, shot very vigorously in a temperature of 60°; he is "much inclined to believe that the mango might be raised in great abundance, and considerable perfection, in the stove, in this country; for it is a fruit which acquires maturity within a short period. It blossoms in Bengal in January, and ripens in the end of May." (Hort. Trans. vol. ii. 463.)

5968. The mango, or mango-tan. — Gorginia Mangosta, L. (Lam. Ill. t. 405.) Dod5ec. Monog. L. and Guttif-

erz, J. (fig. 330.) It is a tree rising nearly twenty feet high, and is often cut to prop up the tan-pat; and it is looked upon in Batavia as the tree most proper for adorning a garden, and affording an agreeable shade. It was introduced to this country by Dr. Gore, according to Dr. Gore (Phil. Trans.), "It is esteemed the most delicious of the East Indian fruits, and a great deal of it may be eaten without any inconvenience; it is the only fruit which sick people are able to eat unboiled. It is raised with success in October, is eaten with some relish in almost every disorder; and we are told that Dr. Solanier in the last stage of a putrid fever in Batavia, found himself insensibly recovering by sucking this delicious and refreshing fruit. The pulp has a mixture of the tart and sweet, and is no less satisfactory than pleasant." 5999. Propagation and culture. It may be raised from seeds or cuttings; and in procuring the seeds from the East Indies, the same precautions must be taken as suggested for those of the mango. (5967.) More says, "I have never endeavored to obtain the plants, is sow the seeds in tubs of earth in their native country, and when the plants have obtained strength, they may be brought to Europe; but there should be great care taken to screen them from salt water in their passage, as also not to give them too much water when in a cold or temperate climate." When the plants arrive in Europe, they should be carefully transplanted each into a pot filled with light kitchen-garden earth, and plunged in the tan-bed, and shaded from the sun till they have taken new root. Then treat them as suggested for fruiting other stove plants.

6000. The pistachio, or European date-palm, (Diospyros Lotus, L. (Mill. Ic. t. 116.) Polyg. Diac. L. and Ebeneceer, B. P.) is a small tree, rising six feet high, with spreading branches, and large shining lance-

6001. Propagation and culture. It may be raised from seeds sown in a hot-bed, and afterwards hardened off; but when it is used as a fruiting plant, it may be procured from Genoa of a good size, and, planted in a temperate forcing-house, it will not fail to mature its fruit.

6002. The granadilla, or little pomegranate. This name is applied to the edible fruit of five species of the Passiflora genus; Monadel. Pentan. L. and Passiflora, J. The common character of which is that of climbing herbaceous plants, woody at bottom, generally with lobed leaves, and all natives of warm climates.

6003. The granadilla, or granadilla-vine of the French, is the P. quadrangularis, L. (Bot. Reg. 14.) The leaves smooth, oval and suborbiculate, five or six inches long and entire; stem luxuriant and four-cornered. The flowers small, soft, red within and white on the outside, an appear in August and September, both flowers and fruits growing at the same time. The fruit, Sabine describes (Hort. Trans. iii. 100.) as very large, of an oblong shape, about six inches in diameter, from the stalk to the eye, and fifteen inches in circumference. It is extended from the axis of a green stalk now when ripe, soft and leathery to the touch, and quite smooth; the rind is very thick, and contains a succulent pulp of a purple color (which is the edible part), mixed with the seeds, in a sort of sack, from which it is readily separable. Wine and sugar are commonly added to it, when used. The flavor is sweet, and slightly acid, and it is very grateful to the taste. It is in a hot climate, and a native of Jamaica, and other West India islands, where it grows in the woods, and was cultivated by Miller in 1768, as a stove plant. It has since been successfully cultivated for its fruit in a few places, as at Lord Harewood's (Hort. Trans. iv. 60.), Earley Hall, &c. It is a native of the Cape of Good Hope, and sweet calabash, is the P. maliformis, L. (Bot. Reg. 2.) The rind has a thick triangular stem, with leaves ovate, and six to nine inches, long, and four, cordate, and the middle of a lively green. The flowers are sweet-scented, large, of a pale red and blue: "the fruit round, smooth, about two inches in diameter, of a dingy yellow color when ripe; the coat is hard and stringy, nearly a quarter of an inch thick, and resembles gelatinous pale yellow pulp, in which many oblong black seeds are lodged," (Hort. Trans. iii. 101.) and is eaten like that of the former species. It is a native of the West India islands, and was introduced here, and cultivated by Miller in 1731. It has borne fruit in the stove of the Bishop of Durham in Oxfordshire, and at Vere's, Kennington Gore.

6004. The yellow granadilla, or water-lily, Pounon de la Liane of the French, is the P. taurifolia, L. (Bot. Reg. 13.) It has a suffrutescent stem, with divaricating filiform branches, oval smooth leaves, and very long tendrils. Flowers red and violet, sweet scented; the fruit about the size of a man's egg, but rather more elongated, and tapering equally at both ends; when ripe, it is yellow, and dotted with various spots; it contains a whitish pulp, which, in the West Indies, is usually sucked through a small hole made in the rind; the rind is tough, soft, and thin; the juice has a peculiar
EXOTIC FRUITS LITTLE KNOWN.

873

aromatic flavor, is delicately acid, and allays thirst agreeably. It is a native of Martińique and Surinam, and was introduced here in 1690. It is grown in the house, but has not yet been cultivated for its fruit.

6001. The pulp-fruit, granadilla, or May apple, is the P. incarnata, L. (Abb. in Geor. t. 12.) The root is perennial, sending up annually a number of herbaceous shoots, with three-lobed leaves, and sweet-scented flowers, variegated with purple, and appears from July to September. The fruit when ripe is about the size of an apple, orange-colored, with a sweetish yellow pulp. It is a native of Virginia, was cultivated in the open air by Parkinson in 1629, and afterwards by Miller in the store, with whom it bore fruit.

6008. Propagation and culture. All the sorts may be propagated from seed, layers, and even cuttings; but layers come soonest into bearing. Having procured plants with good roots, plant such as are intended to fruit in a border in the store, and train them to a trellis near the glass; they will in general produce fruit in two years. In seedling fruit, the first year. All the species will fruit in even large pots; but Sabine says, the "best method is, to plant them in an angle of the bark-bed, which has been parted off, either by boards or nine-inch brick-work, as low as the pit goes. At the bottom of the cavity, formed by this division, should be laid some brick-rubbish, over which may be placed a layer of earth, and then covered with equal parts of very old man, and a compost of leaf-mould and rotten dung. Here in the roots will strike freely, and will even spread through the partition into the pit, growing into the fresh tan. Such roots may be trimmed and reduced whenever the tan is changed, and the time of the season has been given, or the old in the bottom of the pit, in which the protruded roots may remain undisturbed. They do not require the full heat of the pine-stove, for they flourish best in a temperature of from 65 to 70 degrees; but they do not bring their fruit to perfection if kept in a common greenhouse or conservatory, though they have been trained and grown in it. As the temperature of the inclined glass of the store: the first flowers will appear in May, and the blooming will continue until September, the fruit setting the whole time; but if it does not set well, it will be advisable to impregnate the stigma, by applying the pollen with a feather. As they grow, the very strong shoots should be cut out fairly; but the earlier produce is best. When the crop is all off, which will be early in January, the heat must be reduced to about 20°, so as to check or stop the growth; this being effected, the shoots must be well cut in. As little old wood as possible, besides the main stem, which rises from the glass, and a few pieces (about two or three feet of each) of the old branches should be retained: for all the shoots grow from the same branch, in the median year, or about the glass: it has been found that the shoots break better, and in greater quantity, from the older wood than from that of two years' standing. In this dormant and reduced state it is to be kept during January and February, after which the necessary heat may be applied to cause it to resume its functions for the ensuing season.

6010. The cocoa-nut tree is the Musa nesieri, L. (Rech. (or. 1. t. 73.) Monocot. Hexam. L. and Palmae, B. P. (fig. 532.) It is an East Indian palm; but cultivated in most places within the tropics. The trees grow to a great height, with leaves fifteen or fourteen feet long; the flowers come out round the top of the trunk of the tree in large clusters, enclosed in a spath or sheath; and the nuts succeed them coming in ten or twelve together. Their form and use is familiar.

6010. Propagation and culture. The nuts are to be planted where they are designed to remain, as the tree will not bear transplanting unless very young. In a moist heat they will push in six weeks or two months. To cultivate for fruit, plant in the centre of the area of a house, twenty-five feet wide, and either lofty, or with a moveable roof, which will admit of being raised as the tree advances in height. In this way, with a strong heat, there can be no doubt this tree would produce fruit in England; but even if it did not, or did not for a great many years, the magnificence of its appearance, under such a mode of treatment, would compensate a curious horticulturist for the labor and expense. Though the cocoa-nuts to be obtained in the shops are supposed to be gathered before ripening, yet they have been found to grow with no other care than planting in a large pot or box of rich earth, and plunging in a banked. It may be observed here, that this is almost the only palm that could be cultivated in this country for perfecting its fruit; for the others being dioecious plants, unless a great number were grown together, there would be no legitimate means of impregnating the female blossoms.

6010. The plantain-tree, Musa paradisiaca, L. Haz. Monog. L. and Musaceae, P. S.) rises with a soft, herbaceous, central stalk, fifteen or twenty feet high, with leaves issuing from the top, often more than six feet long, and near two feet broad; the spike of male and female flowers appear from the centre of the leaves, and is succeeded by puffed-shaping fruits, eight or nine inches long, above an inch in diameter, yellow when ripe, of a soft, smooth, and pleasant flavor, the spike or stem so large as to weigh upwards of forty pounds. It is a native of the East Indies, and other parts of Asia, and probably of Africa,
and was cultivated at Hampton Court in 1690. Gerrard says, the pulp eats something like that of a muskmelon; he calls the plant Adam's apple-tree, from a notion that it was the forbidden fruit of Eden; others suppose it to have been the grape brought out of the promised land to Moses. Dumper says, it is the king of all fruit, not excepting the cocoa itself. There are numerous varieties.

6012. The banana-tree (M. sapientum, L.) (fig. 553) differs from the plantain in having its stalks marked with dark-purple stripes and spots, and the fruit is shorter and rounder. Some botanists, however, consider them as only one species. The fruit is mellower than the other, is eaten raw or roasted, in fritters, preserves, marmalades, and the fermented juice affords an excellent wine. It has been fruited for several years at Wynnstay, the seat of Sir W. W. Wynne, in Denbighshire. Specimens were sent to the Horticultural Society in August 1813, which were between five and six inches long, and possessed an agreeable, juicy, and acid flavor, and the produce from a single plant is "so abundant, as to entitle the banana to be considered as a useful fruit for the table.”

6013. Propagation and culture. Suckers rise from the root, which should be planted in light rich earth, in pots, and afterwards, if the plant is cultivated for its fruit, planted in a bed or plot of earth, kept rather moist. The plant at Wynnstay was planted in the pit of a stove about 1811. "It was then about six feet high, with a single stem. In each succeeding year it has produced a bunch of fruit; but in the present year (1819) two bunches; the first was ripe in May, the other in August, having about four dozen fruit on each bunch. The plant is now sixteen feet high, and measures three feet round at the bottom." (Hort. Trans. iv. 138.)

6014. The bread-fruit. — Artocarpus incisa, L. (Rumpl. Amph. 3. t. 31) Monoc. Monan. L. and U. de Breb. & Fruit-sap, Fr. and Brod- baum, Ger. (fig. 554.) It is a stone tree, growing in the South Sea Islands, to the height of a moderate sized oak, with alternate leaves, deeply gashed, glaucous, and two feet long. Amons to the outward branches, violet-colored, pellucid, male and female on the same twig. The whole tree and the fruit, before it is ripe, abounds in a very tenacious and five inches long, and possessed an agreeable, juicy, and acid flavor, and the produce from a single plant is "so abundant, as to entitle the banana to be considered as a useful fruit for the table.”

6015. Propagation and culture. This tree will grow either from seeds, layers, or suckers; the latter the plants send up abundantly in their native climates. They succeed best in a rich soil; and to induce them to produce fruit, should be treated as already advised for other stone fruits not easily fruited. As the bread-fruit tree has been introduced in the West India Islands, the shortest way would be to procure good sized plants from Jamaica or St. Vincent's though they may be occasionally obtained from the London nurseries.

6016. The true lotus (Ziziphus lotus, W.), the jujube-tree (Z. Jujuba, W.), and the kaki (Diospyros Kaki, W.), are branching shrubs or small trees of the easiest culture in Italy, Barbary, and China, and abundant bearers. They might readily be cultivated in this country, and as the jujube grows in hedge-rows about Genoa and Nies, it is probable it would bear fruit abundantly in a green-house. The jujube is served up in Italy as a dry sweetmeat. The fruit of the kaki are orange or apple shaped.

6017. Other exotic fruits. The following have been enumerated by Lindley (Hort. Trans. v. 82.), as merit ing introduction, or where already introduced, to be cultivated as dessert-fruits.

6018. Of African fruits we might have from Sierra Leone, the cream-fruit, country cherries, country plums and figs; from Congo, the conte, mabocche, gaugi, safu, and anona senegalensis; from Loango, the cazou as large as a melon; from Madagascar, the vanato, voutaca, vocourem, azonualaa, and alamotou.

6019. From the West Indies, the sappodilla-plum (Acharas Sapota), country cherries which are various species of Malpighia, the callimatto-tree (Chrysobalanus Icaco), the star-apple (Chryspophyllum Caninio), the country plums (Spondias) various species, the sea-side grape (Coccoedera usifera), the garlic-pear (Cra- taea Topia), and various species of cactus. Most of these fruits are cultivated both in the West India Islands and on the American continent, and plants of all of them may be had from the London nurseries.

6020. From South America various fruits may be introduced from Guiana, the tapaculo (Carica microcarpa ?), the pinaoi (Anona punctata), the piniaou (A. longifolia), the marmalade-box of Medinam (Medinam lusitana), the mango (Mangifera indica), &c. From Brazil, the saba, &c. From Peru, &c. the schoon (Leonia gysyscarpa), the queule or keule (Gomortega nitida), and others of less note.

6021. From Asia the first fruits in the world have been obtained, and others are yet to introduce. From the Indian Archipelago, the lansch (Lansium domesticum), a fruit considered as next to the mango, and durian, the rose-water jamou (Eugenia aquosa), and other species; the blushing (Averrhoa Carambola), the cheremi (A. acida), the rambutan (Nephelium lappaceum), the tomi-tomi (Flacourtia inermis), the Xanthochymus dulcis, Sundoricum indicum, and some others. From the continent of India, the mango, or elephant-apple (Egle Mangifera), the yellang (Ficus), the saptam (F. Indica), the casva (Baccauda dills), the iwara namady (Xanthochymus papuensis), the caranda (Carissa Carambola), the launzan (Buchanania latifolia), and others. From China and Japan many new sorts of peaches, and peaches, it is supposed, may be obtained, and probably also apples and other European fruits; the Poma- ceae and Prunaceae occupying the place in higher latitudes which the Myrtaceae, Cuthifera and Tere- bintaceae do in countries nearer the equator. From the Society Islands, the Otahi apple (Spondias cytherae), &c. Though we think it probable that few or none of these, grown in this country, would be
found to equal our best peaches, pears and plums, or even gooseberries and strawberries; yet we cannot but wish to see this or the contrary proved by the wealthy and curious horticulturist.

Sect. IV. Exotic Esculent, not hitherto cultivated as such.

6022. Of exotic esculent, some, as the yam and sweet potato, are worthy of being experimented on with a view to their naturalisation as articles of food; and even as furnishing a variety of esculent root, they deserve to be grown and sent to table, where there is a complete or extensive garden establishment.

6023. The West Indian yam (the inname of the Portuguese, and igname of the French,) is the name applied to several species, with their numerous varieties of the genus Dioscorea. L. Dicucus. Hizar. L. and Dioscorea J. They are climbing, perennial, herbaceous plants, with tuberous roots, and axillary flowers in spikes or racemes. The name yam is more particularly applied to the D. sativa. (Rheed. Mal. 8. t. 51.) (fig. 535.) This plant has tender stalks, climbing to the height of eighteen or twenty feet, and furnished with smooth-nerved roundish leaves. From the base of the leaves arise spatoles of small flowers of no beauty. The root is flat, brownish, a foot broad, and nearly palmed like those of some of the orchidese. It is a native of, and cultivated extensively in, Africa and the East and West Indies, and was introduced here from the latter country in 1733. The roots are moist, easily of digestion, palatable, and not inferior to any roots now in use, either for delicacy of flavor or nutriment. They are eaten instead of bread, either roasted on the embers or boiled; the flower is also made into bread and puddings.

6024. The D. alata, (Rheed. Mal. 7. t. 38.) or winged yam, is in equal, if not more universal cultivation than the former species. Its roots are frequently three feet long, and weigh thirty pounds. Of both these species there are numerous varieties, differing in the size and form of their roots.

6025. Propagation and culture. They may be propagated like the common potato, and cultivated in nearly the same manner as the forced potatoes. Brown (Hist. of Jam.) affirms, that the roots must be cut so as to leave a little of the skin to each piece, for by that alone they germinate; the roots having no apparent buds or eyes, but casting out their weakly stems from every part of the surface alike. They are planted commonly in August, and are ripe in November or December following.

6026. The Spanish, or sweet potato, is the Convolvulus Batatas, L. (Rheed. Mal. 7. t. 20.) Pent. Monog. L. and Convulvolaceae, B. P. (fig. 566.) It is a herbaceous perennial, with a round stem, hispid, prostrate, creeping, of a whitish-green, putting out scattered, oblong, acuminate tubers, purple or pale on the outsides. The leaves are angular, on long petioles; the flowers purple, on upward peduncles. It is a native of both the Indies, and was introduced here, and cultivated by Gerrard in 1597. He calls the roots potatus, potares, or potatoes, and says, that they are by some named skirretes of Peru. They flourished in his garden till winter, when they perished and rotted. Batatas were then sold at the exchange in London, and are still annually imported and put on the market. Miller observes, that the tubers of the batatas are sweet, sapid, and nourishing. They are very commonly cultivated in all the tropical climates, where they eat not only the roots but the young leaves and tender shoots boiled. There are several varieties, if not distinct species, differing in the size, figure, and taste of the roots.

6027. Propagation and culture. In warm climates this plant is cultivated in the same manner as our potato, but requires much more room, for the trailing stalks extend four or five feet every way, sending out large tubers, from forty to a plant. In the national garden at Paris, the plants are raised in a hot-bed, and about the middle of May, transplanted in the open ground, where they are earthened up, and otherwise treated like the potato. In warm seasons they produce a tolerable crop, and we have been informed by Professor Thouin, that he hopes, after several years, at least so far to acclimatize the plant as to fit it for field-culture in the south of France. Leclercq, who grows it in the same manner, also strongly recommends its culture. Both consider it as much lighter food than the common potato, and equally nourishing. In England, Miller observes, the roots must be planted on a hot-bed in the spring, and if the plants are kept covered in bad weather with glasses, they will produce flowers and many small tubers from the joints; but if they are exposed to the open air, they seldom make much progress. This, however, ought not to discourage the curious or patriotic horticulturist, either in his attempts to raise the roots for the table, or to acclimate the plant.

6028. The caper (Capparis spinosa, L. Polyan. Monog. L. and Capparidceae, J.) (fig. 537.) is a trailing shrub, a native of the south of Italy and Sicily, where it abounds on rocks, ruins, and old walls: it has been long cultivated in France, and was introduced in this country in 1596, as a stowe plant; but there is reason to believe it may be naturalised. It is cultivated, Neill observes, in the neighborhood of Paris, with no other protection than that of being trained against a low wall, and the shoots in winter laid down and covered with litter or fern, like those of the fig.
In the garden at Camden House, Kensington, a caper-tree stood alive in the open air for near a century: it had a south-east aspect, and was well sheltered from the north: it had no covering, and was generally much injured by the frost; but the roots of this plant being particularly strong and vivacious, it made strong shoots, and produced flower-buds every year. It is probable, therefore, that a plantation, so situated, if covered every autumn with litter, mats, or ferns, would succeed. Such a plantation, not trained on walls, but planted in an open compartment, would, like those near Toulon, in France, have the general appearance of a plantation of brambles, and might be yearly covered with very little trouble. Neill suggests, that a hardy variety might possibly be obtained by repeatedly raising from seed, at first in Guernsey or Jersey, and the plant thus gradually inured to this country. The part used is the flower-bud, which forms a well known pickle, and an article of considerable commerce from Sicily, and other islands in the Mediterranean.

6029. Propagation and culture. It may either be raised from seed, cuttings, or pieces of the root. The authors of the Cours complet d'Agriculture prefer the mode by cuttings, and direct them to be cut a foot long, and planted in autumn. The autumn following, they will be fit to remove to a general plantation. They describe two modes of culture; one, that of planting in walls, where no further care is wanting, but that of gathering the buds; and the other, that of planting in quincunx in open compartments, like other fruit-shrubs; the latter mode is greatly to be preferred.

6030. The sativis, or edible atramentaria. — Atramentaria Salisii, B. M. (Bot. Mag. 1815); and S. ciliata, Hort. Typum, vol. iii. H. Monog. L. and Asphodelaceae, E. P. Fr. is a herbaceous plant of great beauty, a native of Peru, and introduced in 1806. It is cultivated in the West Indies, where its roots are eaten like the potato. It was here in 1811, in the Comte de Vande's garden at Bayswater. It requires the temperature of the stove, and may be cultivated in a hot-bed like the early potato.

6031. The bread-root. — Paeonoe sculentum, Fr. (Parsb. Amer. t. 22.) Dodeleph. Decan. L. and Leguminosae, J. It is a perennial herbaceous plant, a native of Missouri, and introduced here in 1811. It will grow in the open air, but requires the protection of a frame to produce abundant crops of roots, which are used like those of the potato in the countries where it is a native.

6032. The pi-tol, or water-chestnut of the Chinese. — Scirpus tuberosus, Rox (Rox. iii. 26.) Triand. Monog. L and Cyperaceae, B. P. (fig. 538.) It is a stoloniferous rush, without leaves, excepting a slender short sheath or two at the base of the stem. On the stolones grow tubers which grow tubers in high estimation among all ranks of the Chinese, not only as a pot-root, but as a medicine. It is eaten either boiled or raw.

6033. Cultivation. — "The maa-tai, pu-tai, or pi-tai, of Abbo Grosier, grows in tanks; these are manufactured for its reception about the end of March. Thus a tank being drained of its water, small pits are dug in its bottom; these are filled with human manure, and exposed to the sun for a fortnight; their contents are then finely blended, and the slaty bed of the tank, and the slips or roots of the plant deposited therein; the water is now returned to the tank, and the new crop of tubers comes to perfection by the first of September." (Rox. Corom.)

6034. The corn-lemoine, or rush-root. (Cyperus sculentus, L. Triand. Monog. L and Cyperaceae, J. Souchet censible, Fr. and Zizole di Terra, Ital.) is a fibrous-rooted grass, with small round tubers hanging from the fibres, about the size of peas, which taste like chestnuts or almonds. It is a native of Italy and Montpellier, and is cultivated in some parts of the Europe and Germany for food. The tubers are planted in spring, and taken up in October, and preserved for winter use in the manner of potatoes. It might probably be cultivated in this country in dry warm situations, or in a frame. (Dom Jardinier.)

6035. The eatable hibiscus. — Hibiscus sculentus, L. Monsaluf, Polyan. L and Malvaceae, J. Gomba or Guerro, Fr. This is a stowe annual, a native of the West Indies, and introduced in 1692. A soft herbaceous stalk rises from three to five feet high, with crenate leaves, and axillary, pale sulphur-colored flowers, succeeded by capsules. These, in the West Indies and the south of France, are put green into soups, or eaten with butter. In the south of France it is cultivated in the open air for this purpose; and at Paris it is treated as we do the capiscum and love-apple. A similar treatment would, no doubt, succeed in this country.

6036. The arrachano, of the order of Umbelliferae, J., is a South American plant, said to resemble the Asparagus in habit; but probably Aspium Americanum, D, possibly Liguusticum nova adsp. The main roots divide into four or five others, which grow to the size of cows' horns. These are used in the manner of potatoes by the inhabitants of Santa Fé and the Caraccas. They are light, starchy, and easy of digestion. The plant is said to thrive best in the elevated regions of mountains, where the medium heat does not exceed 599 or 600. (Annals of Bot. l. 400.) The name of this plant has not yet been determined, but, through the exertions of the Horticultural Society, it has recently been introduced to England, and will soon be subjected to examination and improvement.

6037. Other esculenta. To the above we might add, the Dohall, recommended to be grown for its tubers by Thibault-de-Berneaud. The Dolichos Soja, a stowe annual, the seeds of which form, or ought to form, the chief ingredient in the fish-sauce of that name. The earth-nut of South America (Arrachis hypogaea, L.) is raised in many places near the open air. The Convolvulus reptans, a shrubby stowe plant, grown in China, in trenches filled with water, and used as a spinaeous or oleraceous plant. The Basillia nigra, and other species, stowe biennials, used for the same purpose: the European and Chinese water-calhops (Trapa natans and bicorona), both greenhouse, but fruitedit by Lord Lambton, in the steph. Trans. iv. 563.) The T. natans is grown in the ponds in Holland, according to Professor Martyn, and the nuts are used there as chestnuts both by men and hogs; and Neill informs us that the canal at Versailles is covered with the plant, and that the fruit is sometimes served up at table. There, and a variety of others, the curious cultivator will find noticed in botanical works and books of travels, and will enjoy greater satisfaction in discovering them himself than in finding them ready named for his experimental inquiries.
Horticultural Productions which may be expected from a first-rate Kitchen-garden managed in the best Style.

6038. The sources of edible enjoyment afforded by a first-rate kitchen-garden are numerous and varied; and consequently a proprietor, who spares no expense on this department, ought to be informed of what he has a right to expect, subject, however, to the drawbacks of bad situations, uncertain seasons, and unforeseen accidents. Many gardeners object to tables of this kind, as leading to unreasonable expectations, disappointments, and quarrels, and as, in short, enlightening too much their employers. On this we shall only observe, that the more a proprietor requires, the more he must conform to the conditions on which alone these products are to be expected. As to the subject of enlightening masters, much might be said in its favor, and nothing founded in right reason against it. It is only by a knowledge of gardening that a master can distinguish a bad gardener from a good one; and only from this appreciation that a good gardener can be properly valued and rewarded. Community of knowledge must be better than no community at all. A man who employs a gardener as he does a tailor, merely to supply his wants, may look on him as a very convenient machine, and useful to have about his premises; but where a knowledge and taste for gardening exists in the employer, one point of union is formed between him and his servant, which must be productive of a certain degree of humanity, if not of mutual respect and consideration. It is only bad gardeners, therefore, that have to fear the dissemination of knowledge among their masters.

In a work of this nature, however, in which the object is more to give the opinion of others than our own, we subjoin what Mr. Pitfall observes on the subject, which may be reckoned the opinion of most men of his order. "The book called Every Man his own Gardener," he says, "gives a list of what fruits, &c., gentlemen may expect from their gardens in every month of the year; such a list not only of fruits, but of flowers and esculent vegetables, which nature, assisted by artificial means, is incompetent to produce in every month of the year in any country, in any degree of latitude under the sun; hence, from lists of this kind being given in books said to be written by practical gardeners, ariseth strife between masters and mistresses and their servant-gardeners." (Gard. Rem. Pref. xxviii.)

Sect. I. January.—The Productions arranged in the Order in which they have been treated in the preceding Chapters.

6040. Hardy fruits from the open garden, orchard, or fruit-room. Apples, pears, quinces, medlars, services from the fruit-room. Some peaches and moreliei berries, carefully preserved on the trees. Some thick-skinned gooseberries, currants, and grapes from the greenhouse. Some dried fruits of the same sort with nuts hung up in the fruit-room. Some red, white, yellow, and red-beet, chestnuts, filberts from the fruit-room. Sloes from the husk, and hawthorne, and sometimes a few cloudberries.

Sect. II. February.

Yams and Spanish potatoes.

6042. Culinary vegetables from the open garden or garden-stores. Scotch or Strasburgh cabbage, savoy's, broccoles, Brussels sprouts, and, if a mild winter, cabbage-colworts, broccolic, Haricot-beans, and soup-peas from the seed-room. Potatoes, Jerusalem artichokes, turnip, carrot, parsnip, red beet, skirret, scorzonera, and salady. Spinage, if a mild winter. Onions, leeks, garlic, shallot, and rocambole. Sea-kale from covered beds. Lettuce, ending celery. American and winter cress. Parsley, if protected, horse-raddish, and dried fennel, dill, chervil, &c. Thyme, sage, rosemary, and lavender from the open garden; dried marigolds, basil, &c. from the fruit-room. Dried and dried marigolds, savoy, mint, basil, &c. from the herb-room. Rhubarb-stalks from covered roots; asirt, carinder and watercress, from the herb-room; and dried red cabbage and samphire. Wild rocket, wild spinach, sauce-alone, and sorrel, if a mild winter. Mushrooms from covered ridges. Sea-belt, or sweet fucus, dried.

Sect. III. March.

6043. Hardly fruits from the open garden, orchard, or fruit-room. Apples, pears, quinces, medlars, services from the fruit-room. Some peaches from the greenhouse. Some dried fruits from the fruit-room. Some dried grapes and currants from branches hung up in the fruit-room. Almonds, walnuts, chestnuts, filberts from the fruit-room. Some red, white, and yellow hazel nuts hung up in the fruit-room.

Sect. IV. April.

6045. Culinary vegetables from the open garden or garden-stores. Brussels sprouts, broccoles of sorts, especially the early green ones, Parisians, and Paris and other sorts from the seed-room. Potatoes, Jerusalem artichokes, turnip, carrot, parsnip, red beet, skirret, scorzonera, and salady. Spinage occasionally, if mild. Onions from the root-room; Welsh onions, chives from the root-room; scallions, from the root-room; rocambole, from the root-room. Sea-kale from covered beds. Lettuce, ending celery. American and winter cress. Parsley, if protected, horse-raddish, and dried fennel, dill, chervil, &c. Thyme, sage, rosemary from the open garden; and dried marigold, basil, mint, savoy, &c. from the herb-room. Rhubarb-stalks from covered roots; asirt, carinder and watercress, from the herb-room; and dried red cabbage and samphire. Wild rocket, wild spinach, sauce-alone, and sorrel, if a mild winter. Mushrooms from covered ridges. Sea-belt, or sweet fucus, dried.

6046. Hardly fruits from the open garden, orchard, or fruit-room. Apples, pears, quinces, medlars, services from the fruit-room. Some dried grapes. Almonds, walnuts, chestnuts, filberts from the fruit-room. Some red, white, and yellow hazel nuts hung up in the fruit-room.
PRACTICE

PART III.

IV. APRIL.

Culinary vegetables from the open garden, or garden-stores. Brussels sprouts, borecole, cress, scorzonera. Spinage, beet-root, beet-root-salad, salsify, radish, turnip, carrot, red, beet, parsnip, rutabaga, carrots, parsnips, rutabagas, and turnips from the root-room. All sorts of field potatoes, scarlet, yellow, white, and red, from garden-stores.

V. MAY.

Culinary vegetables from the open garden, or garden-stores. All sorts of scarlet, yellow, white, and red, from garden-stores. Asparagus, sea-kale from the root-room. All sorts of red, yellow, and white, from garden-stores. Rhubarb-stalks from garden-stores. Artichokes, cauliflower, broccoli, brussels sprouts. Spinage, beet-root, beet-root-salad, salsify, radish, turnip, carrot, red, beet, parsnip, rutabaga, carrots, parsnips, rutabagas, and turnips from the root-room. All sorts of field potatoes, scarlet, yellow, white, and red, from garden-stores.

VI. JUNE.

Culinary vegetables from the open garden, or garden-stores. All sorts of scarlet, yellow, white, and red, from garden-stores. Asparagus, sea-kale from the root-room. All sorts of red, yellow, and white, from garden-stores. Rhubarb-stalks from garden-stores. Artichokes, cauliflower, broccoli, brussels sprouts. Spinage, beet-root, beet-root-salad, salsify, radish, turnip, carrot, red, beet, parsnip, rutabaga, carrots, parsnips, rutabagas, and turnips from the root-room. All sorts of field potatoes, scarlet, yellow, white, and red, from garden-stores.

VII. JULY.

Culinary vegetables from the open garden, or garden-stores. All sorts of scarlet, yellow, white, and red, from garden-stores. Asparagus, sea-kale from the root-room. All sorts of red, yellow, and white, from garden-stores. Rhubarb-stalks from garden-stores. Artichokes, cauliflower, broccoli, brussels sprouts. Spinage, beet-root, beet-root-salad, salsify, radish, turnip, carrot, red, beet, parsnip, rutabaga, carrots, parsnips, rutabagas, and turnips from the root-room. All sorts of field potatoes, scarlet, yellow, white, and red, from garden-stores.

VIII. AUGUST.

Culinary vegetables from the open garden, or garden-stores. All sorts of scarlet, yellow, white, and red, from garden-stores. Asparagus, sea-kale from the root-room. All sorts of red, yellow, and white, from garden-stores. Rhubarb-stalks from garden-stores. Artichokes, cauliflower, broccoli, brussels sprouts. Spinage, beet-root, beet-root-salad, salsify, radish, turnip, carrot, red, beet, parsnip, rutabaga, carrots, parsnips, rutabagas, and turnips from the root-room. All sorts of field potatoes, scarlet, yellow, white, and red, from garden-stores.

IX. SEPTEMBER.

Culinary vegetables from the open garden, or garden-stores. All sorts of scarlet, yellow, white, and red, from garden-stores. Asparagus, sea-kale from the root-room. All sorts of red, yellow, and white, from garden-stores. Rhubarb-stalks from garden-stores. Artichokes, cauliflower, broccoli, brussels sprouts. Spinage, beet-root, beet-root-salad, salsify, radish, turnip, carrot, red, beet, parsnip, rutabaga, carrots, parsnips, rutabagas, and turnips from the root-room. All sorts of field potatoes, scarlet, yellow, white, and red, from garden-stores.

X. OCTOBER.

Culinary vegetables from the open garden, or garden-stores. All sorts of scarlet, yellow, white, and red, from garden-stores. Asparagus, sea-kale from the root-room. All sorts of red, yellow, and white, from garden-stores. Rhubarb-stalks from garden-stores. Artichokes, cauliflower, broccoli, brussels sprouts. Spinage, beet-root, beet-root-salad, salsify, radish, turnip, carrot, red, beet, parsnip, rutabaga, carrots, parsnips, rutabagas, and turnips from the root-room. All sorts of field potatoes, scarlet, yellow, white, and red, from garden-stores.

November. December.
The culture of flowers was long carried on with that of culinary vegetables, in the borders of the kitchen-garden, or in parterres or groups of beds, which commonly connected the culinary compartments with the house. In places of moderate extent, this mixed style is still continued; but in residences which aim at any degree of distinction, the space within the walled garden is confined to the production of objects of domestic utility, while the culture of plants of ornament is displayed in the flower-garden and the shrubbery. These, under the general term of pleasure-ground, encircle the house in small seats, and on a larger scale embrace it in one or more sides; the remaining part being under the character of park-scenery. Many of the most interesting plants belonging to this branch of culture are natives of warm climates, and require the protection of glass and artificial heat. On a limited scale, such plants are grown in the culinary-forcing-houses, or in green-houses, or botanic stoves, connected with the others in the kitchen-garden. In complete residences, however, the culture of exotics forms a distinct department of ornamental horticulture, and the hot-houses requisite for this purpose are placed in the flower-garden, or variously arranged within the precincts of the pleasure-ground. In both departments, separation is attended with the usual advantages resulting from a division of skill, labor, and effect. Floriculture is obviously of limited interest and utility, compared to horticulture; much less has accordingly been written on it, and our view of modern practice will, therefore, be proportionately brief. The order adopted, is the formation, planting, and general culture of the flower-garden; the formation, planting, and general culture of the shrubbery; the design and general culture of the floricultural hot-houses; the catalogue of plants and trees used in ornamental horticulture; and, lastly, the monthly table of floricultural productions.

Chap. I.

Of the Formation of the Flower-garden.

6076. The situation of the flower-garden, as of every department of floriculture, should be near the house, for ready access at all times, and especially during winter and spring,
when the beauties of this scene are felt with peculiar force. "The flower-garden," Neill observes, "should form an ornamental appendage to the mansion, and be easily accessible in all kinds of weather. There is no objection to its being seen from the windows of the house: on the contrary, this is sometimes considered as desirable." Nico, as we have seen (2492.), approves of having the various gardens of a place combined, and placing them at no great distance from the house; and Repton strongly recommends this practice.

6077. Abercrombie says, "While the kitchen-garden is concealed by buildings or plantations, the flower-garden and pleasure-ground should stand conspicuously attached to the family residence. When the horticultural establishment includes a conservatory, it is proper to have it in sight, and connected with the ornamented grounds; because the style of such a building, the plants within, and the scene without, under a tasteful arrangement, harmonise in character and effect. The botanic-garden, the range of stoves, and all the departments, a visit to which renders a walk about the grounds pleasing and interesting, should be at hand."

6078. The author of the Florist's Manual confines her observations to the "construction of that humble flower-garden," which she calls "the common or mingled flower-garden." "This," she says, "should be situated so as to form an ornamental appendage to the house, and where the plan of ground will admit, placed before windows exposed to a southern or south-east aspect; and although to this position there may appear the objection of the flowers turning their petals to the sun, and consequently from the windows, this predilection in the tribe of Flora for the rays of that bright luminary, will produce the same effect in whatever place our flowers may be situated, when in the vicinity of a building, as they invariably expose the front of their corols to the lights from which both the petals of flowers, and the leaves of plants are believed to derive material essential to their existence." She adds, "when apart from the house, the mingled flower-garden may be introduced with great advantage, if situated so as to form a portion of the pleasure-ground; in this case it should not be distinct from the house, but so contrived as to terminate one of the walks of the home shruberies." (Flor. Man. p. 10. 15.)

6079. To place the flower-garden south-east or south-west of the house, and between it and the kitchen-garden, is in general a desirable circumstance. In a design for a villa farm (fig. 2390.), supposing the entrance-front of the house (a), to face the north-west, then the farm-offices (b), horse-pond (c), &c. may be placed to the north-east; the kitchen-yard (d) and livery-stable-yard (e) to the south-west: against these may be placed the exotic hot-houses, looking to the flower-garden (f), and beyond this the American garden (g), and lastly, the kitchen-garden (h), and walk through the farm (5). If concealed approaches to the farm and stable-offices (c, n) and from the kitchen-garden to the kitchen (h, e, d) be contrived, such an arrangement will be found to combine both elegance and economy, and to admit of bringing the wire fence (m), which separates the mown from the fed lawn, near the house, without being unsightly: a desirable object in farm villas, as it saves mowing, and increases pastureage.

6080. In exposure and aspect, the flower-garden should be laid out as much as possible on the same principles as the kitchen-garden (2390.), not only on account of the advantages to be derived from the full influence of the sun during winter on the hot-house department, but also for the better enjoyment of the open air scenes, in weather favorable for walking out of doors. It should not be naturally low in surface, nor of a wet retentive soil, nor rendered damp and gloomy by surrounding high trees, or lofty walls or buildings. If it happen that a house be nearly surrounded by a flower-garden, the variety of aspect thence afforded will be favorable to the continuance of the bloom of our flowers, far beyond what can be obtained if confined to a southern exposure. South, south-east, and east, are the aspects most advantageous to the growth of flowers; and, possessing these varieties of exposure, the bloom of a garden may be protracted some weeks beyond the time it could be preserved under a single aspect.

6081. The extent of the flower-garden depends jointly on the general scale of the residence, and the particular taste of the owner. If any proportion may be mentioned, perhaps, a fifth part of the contents of the kitchen-garden will come near the general average; but there is no impropriety in having a large flower-garden to a small kitchen-garden or mansion, where the taste of the owner leads to such a deviation from common rules. As moderation, however, is generally found best in the end, we concur with the author of the Florist's Manual, when she states, that "the compass of ground appropriated to flowers must vary according to the size of the place of which that ground forms a part, and should in no case be of great extent. If the form of ground, where
a parterre is to be situated, is sloping, the size should be larger than when a flat surface, and the borders of various shapes, and on a bolder scale, and intermingled with grass; but such a flower-garden partakes more of the nature of pleasure-ground than of the common parterre, and will admit of a judicious introduction of flowering shrubs." "To cover twenty acres with mere flowering plants," Abercrombie observes, "producing nothing esculent in the root, leaves, or fruit, would be puerile and ridiculous, as it would exceed the moderation with which nature scatters her ornaments." (Pract. Gard. 238.)

6082. Shelter is equally requisite for the flower as for the kitchen garden, and, where naturally wanting, is to be produced by the same means, viz. planting. The plantation on the side next the garden, should begin with the lowest shrubs, and rise in gradation to the trees, which, unless on the north, or very exposed points, should not be of the tallest kinds. A few elegant shrubs, and one or two trees may be scattered through the scene, either in the dug compartments or in the turf-glades, for the purposes of shelter and shade as well as ornament; but in general, much of either of the two former qualities are highly injurious both to the culture of flowers, and the thick closeness of turf; besides rendering the garden unfit to be resorted to in the winter and spring seasons. Sometimes an evergreen-hedge will produce all the shelter requisite, as in small gardens composed of earth and gravel only (fig. 541.); but where the scene is large (fig. 540.), and composed of dug compartments (a), placed on lawn (b) the whole may be surrounded by an irregular border (c) of flowers, shrubbery, and trees.

6083. Soil. Most of the hardy herbaceous flowers, and the deciduous and evergreen ornamental shrubs, will succeed in a soil of common good qualities, moderately light and mellow. Negatively, the ground should not be excessively strong and clayey; and mere gravel is very intractable. (Abercrombie.)

6084. Nicol observes, that flowers in general "will thrive very well in common garden-earth of a middling texture, if broke fine, to the depth of a foot. Some, no doubt, do better in light than in heavy soils; and the contrary: and others do best in rich humid earth. Bulbous flowers, in general, do best in light sandy earth; though some require a stronger and a richer soil. In general, the soil for these should be formed at least eighteen inches deep, and should be made very fine by the spade, or be put through a coarse screen." In parterres where the finer flowers are cultivated, a variety of soils will be required according to the nature of the plants, as rich sandy loam for bulbs, loamy earth for the primula tribe, bog-earth for American plants; and hence it follows, that, provided the sub-soil be dry, the nature of the surface-stratum is of the less consequence.

6085. Surface. Where the extent is small, and the plants grown to be chiefly florists' owners, or other select kinds, in beds separated by gravelled paths, a level or gentle and uniform slope will be found most suitable; but where the limits are more extensive, and turf and shrubs are introduced, a wavy surface, either naturally or rendered so by art, will have much the best effect. "In reclusse scenes immediately under the eye, art may create a sort of miniature of beautiful ground. Man is but a puny object compared to those of inanimate nature. He may overlook a distant hill, separated by low ground; but a mound of less than three yards in height, placed near the eye, confines the view, and all other objects being shut out, acquires, if apparently a work of nature, a degree of importance in his imagination: winding walks, four feet below the original surface, will supply earth for accompanying them by wavy hills or swells eight feet high. If these hills and swells are formed and contrived as to produce a varied and natural-like whole, with every change of position, a very suitable basis will be raised for a picturesque shrubbery or flower-garden. It was to this sort of art that Pope's garden, at Twickenham, was indebted for so great a variety of beauties in a small space; and the flower-garden at Lord Harcourt's, at Nuneham, was laid out under the eye of Mason the poet, on the same principle." (Ed. Ency. art. Landscape Gardening.)
6086. Water. This material, in some form or other, is as essential to the flower as to the kitchen-garden. Besides the use of the element in common culture, a pond or basin affords an opportunity of growing some of the more showy aquatics, while jets, dropping-fountains, and other forms of displaying water, serve to decorate and give interest to the scene. Besides choice aquatics, the ponds or basins of flower-gardens may be stocked with the gold-fish (Cyprinus auratus), and will serve as a hybernaculum for that elegant and interesting animal the tree-frog (Hyla arborea), so amusing in the gardens of the south of Germany.

6087. The form of a small garden (fig. 541.) will be found most pleasing when some regular figure is adopted, as a circle, oval, octagon, crescent, &c.: but where the extent is so great as not readily to be caught by a single glance of the eye, an irregular shape is generally more convenient, and it may be thrown into agreeable figures, or component scenes, by the introduction of shrubs so as to subdivide the space. "Either a square or an oblong ground-plan," Abercrombie observes, "is eligible; and although the shape must be often adapted to local circumstances, yet, when a garden is so circumscribed that the eye at once embraces the whole, it is desirable that it should be of some regular figure."

6088. Nicol says, "a variety of forms may be indulged in, without incurring censure; provided the figures be graceful, and not in any one place too complicated. An oval is a figure that generally pleases, on account of the continuity of its outlines; next, if extensive, a circle. Next, perhaps, a segment in form of a half-moon, or the larger segment of an oval. But hearts, diamonds, triangles, or squares, if small, seldom please. A simple parallelogram, divided into beds running lengthwise, or the larger segment of an oval, with beds running parallel to its outer margin, will always please." Neill concurs in this opinion.

6089. The author of Hints on the Formation of Gardens, &c. says, "a symmetrical form is best adapted to such parterres as are small and may be comprehended in one view; and an irregular shape to such as are of a considerable size, and contain trees, shrubs, statues, vases, seats, and buildings."

6090. Boundary fence, or screen. Parterres on a small scale may be enclosed by an evergreen hedge of holly, box, laurel, privet, juniper, laurustinus, or Irish whin (Ulex europaus, var. a.); but irregular figures, especially if of some extent, can only be surrounded by a shrubbery, such as we have already hinted at (6082.) as forming a proper shelter for flower-gardens.

6091. Abercrombie says, "for the enclosure, a wall or close paling is, on two accounts, to be preferred on the north side; both to serve as a screen, and to afford a warm internal face for training rare trees. When one of those is not adopted, recourse may be had to a fence of white thorn and holly," &c. (Pract. Gard. 338.)

6092. Rustic fences formed of shoots of the oak, hazel, or larch, may often be introduced with good effect both as interior and surrounding barriers. (fig. 542.)

6093. Laying out the area. This is the most difficult part of the business, and is not to be excelled in without a considerable degree of taste and experience. In laying out
the area of the kitchen-garden, its destination being utility, affords in all cases a safe and fixed guide; but the flower-garden is a matter of fancy and taste, and where these are wavering and unsettled, the work will be found to go on at random. As flower-gardens are objects of pleasure, that principle which must serve as a guide in laying them out, must be taste. Now, in flower-gardens, as in other objects, there are different kinds of tastes; these embodied are called styles or characters; and the great art of the designer is, having fixed on a style, to follow it out unmixed with other styles, or with any deviation which would interfere with the kind of taste or impression which that style is calculated to produce. Style, therefore, is the leading principle in laying out flower-gardens, as utility is in laying out the culinary-garden. As subjects of fancy and taste, the styles of flower-gardens are various. The modern style is a collection of irregular groups and masses, placed about the house as a medium, uniting it with the open lawn. The ancient geometric style, in place of irregular groups, employed symmetrical forms; in France, adding statues and fountains; in Holland, cut trees and grassy slopes; and in Italy, stone walls, walled terraces, and flights of steps. In some situations, these characteristics of parterres may with propriety be added to, or used instead of the modern sort, especially in flat situations, such as are enclosed by high walls in towns, or where the principal building or object is in a style of architecture which will not render these appendages incongruous. There are other characters of gardens, such as Chinese, which are not widely different from the modern; the Indian, which consists chiefly of walks under shade, in squares of grass, &c.; the Turkish, which abounds in shady retreats, boudoirs of roses and aromatic herbs; and the Spanish, which is distinguished by trellis-work and fountains: but these gardens are not generally adapted to this climate, though from contemplating and selecting what is beautiful or suitable in each, a style of decoration for the immediate vicinity of mansions might be composed, greatly preferable to any thing now in use.

694. Abercrombie, Nicol, and most practical gardeners, seem not to understand the subject of style, and their rules amount to little more than that of subdividing the area by paths in different directions. The former author says, "If a piece of ground be set apart for the cultivation of flowers, in what style should it be laid out? This may vary with the quantity of surface, and the object of the cultivator. In the first place, carry a border round the garden, nowhere narrower than three or four feet, unless it may be proper to contract its breadth under the windows of the house; or unless there be a green hedge, on any side, rooted in the level of the garden, which might be expected either to draw the earth, or to encroach on the small plants, in which case flowering shrubs in little slips of mould would do better than dwarf-stemmed flowers. In contact with the surrounding border, may be either a grass-plot or a gravel-walk. The latter is most convenient for approach at all seasons. If the ground be at all dilated, handsome walks, crossing or leading to the centre, will be also requisite: let the principal walks be five or six feet in breadth. The interior of the garden is usually laid out in oblong beds, three or four feet wide, with intervening alleys, two feet wide, or from that down to twelve inches, when it is intended to abstract as little space as possible from the cultivation of the flowers; or, the same end may be obtained by circular or oval beds, with smaller compartments between, of such a form as will leave the alleys of one regular with."

695. According to Nicol, the laying out of flower-gardens is a "matter very much of fancy. Too many gravelled alleys offend the eye, especially if they be much twisted, or run across; as it comprehends the whole at once. Their breadths should be proportioned to that of the beds; nor should they be much
sunk; seldom more than an inch; otherwise they have a bad effect, and look rather like furrows among alleys. They may be edged with box, with daisies, with violets, gentianella, or thrift, according to fancy. But, in order to keep the edges low, thin, and neat, it should seldom be allowed to rise two inches high, or spread two inches wide. A linear box-edging always pleases, if kept quite close and connected." (Kal. 438.)

6696. The author of the Florist's Manual, though she confines her directions to one style, has much more properly left the matter to the practical authors. "It is more difficult," she says, "than may at first appear, to plan, upon even a small scale, such a piece of ground, nor, perhaps, would any but an experienced scientific eye be aware of the difficulties to be encountered in the disposal of a few shaped borders. To the Florist, the more difficult it is in arranging the different parts so as to form a compact glow of color, to effect which it will be necessary to place the borders in such a manner that when viewed from the windows of the house, or from the principal entrance into the garden, one border shall not intercept the beauties of another, nor in avoiding that error, produce one still greater, that of vacancies between the flowers. The small area, which the whole is separated into broken parts, and the general effect lost. Another point to be attended to, is the just proportion of green turf, which, without nice observation, will be too much or too little for the color it is blended with; and, lastly, the breadth of the flower-borders should not be greater than that on which the roots within reach of the gardener's arm would not be subject to the necessity of walking upon the soil, the mark of footsteps being a deformity wherever it appears amongst flowers." (Flor. Man. 13.)

6697. The materials which form the surface of flower-gardens (figs. 543, 544) are gravel (a), turf (b), and dung borders (c), patches (d), or compartments (e), and water (f); but a variety of other objects and materials may be introduced as receptacles for plants, or on the surfaces of walks; as grotesque roots, rocks, flints, spar, shells, scorin in conglomerated lumps, sand and gravel of different colors; besides works of art introduced as decorations, or possess performances, when the old French style (fig. 545) is imitated.

6698. Rock-works. The author of the Florist's Manual observes, on this subject, that "fragments of stone may be made use of, planted with such roots as flourish among rocks, and to which it might not be difficult to give a natural appearance, so far as by bringing forward to the view the utility of these stones in the culture of the vegetables growing thereon. The present fashion of introducing into flower-gardens this kind of rock-work requires the hand of taste to assimilate it to our flower-borders, the massive fabric of the rock being liable to render the lighter architecture of the borders diminutive and meagre: on this point, caution only can be given, the execution must be left to the elegant eye of taste, which, thus warned, will quickly perceive such deformity of beauty and elegance. I must venture to disprove the extended manner in which this vegetable rock-work is sometimes introduced, not having been able to perceive, in any eye-merit in gardens planned and cultivated with every advantage, which evident ingenuity can give them, to the unnatural appearance of artificial crags of rock and other stones misrepresented with delicate plants, in the manner of which the fertile and sheltered border is evidently necessary, being decided that nothing of the kind should be admitted into the simple parterre that is not more or less of use to the growth of some of the species therein exhibited. In pleasure-grounds or flower-gardens on an extensive scale, where we meet with several divisions and stations, the great kinds of vegetable rock-work might probably be well introduced; but to such a magnificent display of art I feel my taste and knowledge wholly incompetent." (Flor. Man. 15.) Where nature offers expensive discipline," the same author adds, "oppose their prohibitory barrier, many of the vegetable tribe may be cultivated to greater perfection, if we appropriate different garden-torders (c), patches (d), or compartments (e), and water (f); but a variety of other objects and materials may be introduced as receptacles for plants, or on the surfaces of walks; as grotesque roots, rocks, flints, spar, shells, scorin in conglomerated lumps, sand and gravel of different colors; besides works of art introduced as decorations, or possess performances, when the old French style (fig. 545) is imitated.

6699. The green-house or conservatory is generally placed in the flower-garden, provided those structures are not appended to the house. In laying out the area, a fit situation must be allotted for this department of floriculture, and the principles of guidance laid down in treating of the situation of the culillary hot-houses (2475.) require here also to be applied. Some recommended the distribution of the botanic hot-houses throughout
the flower-garden or pleasure-ground; but we are decidedly of opinion, that much the best effect is produced when they are connected together in one scene. By the other mode they may form objects agreeable enough to look at externally; but to derive the full effect of their internal beauties, it appears to us that they must be examined in succession and without interruption. No arrangement can be better, in our opinion, than to connect the whole of the botanic hot-houses with the mansion as an introductory scene to the flower-garden. This was Repton's favorite mode, of which, among other examples, he has left that of Ashridge Park. (fig. 546.) Here, to the original lawn and pleasure-ground (1), he made an addition in the same style (2), uniting by walks the following interesting scenes. The botanic stoves and paved terrace (3); broad-sanctuary and holywell (4); pomarium and winter walk (5); the monk's garden (6); arboretum of exotic trees (7); magnolia and American garden (8); embroidered parterre (9); grotto and garden for rock-plants (10); cabinet de verdure (11); mount garden (12); rosarium and fountain (13); connecting and interior walks (14); open terrace and exterior walks (15).

6100. In particular situations, as where the prospect and space are both confined, the plant hot-houses may embrace the house or the court-yard on two or more sides. In a case of this kind, which occurred in our practice (fig. 547.), a large conservatory (a) and aquarium (b) were connected with the library (k): from the conservatory, a green-house (c) led to an aviary (d), and this was connected with a house for standard peach-trees, with vines as climbers (g), by two plant-stoves (e and f). The furnaces were placed in the court-yard (l), and attended from the stable-yard (b), without interfering with the house (i), or the flower-garden (m). The elevation of such a range (fig. 548.) does not pretend to architectural or picturesque beauty; but it is such as is best suited for the culture of plants; and from the peculiarity of the situation it is seen from no point beyond the limits of a very moderate-sized flower-garden.

6101. According to Neill, a green-house, conservatory, and stove should form prominent objects in the different parts of the flower-garden. The author of the Florist's Manual recommends a spring-conservatory, annexed to the house, consisting of borders sheltered by glass, and heated only to the degree that will produce a temperature, under which all the flowers that would naturally bloom between the months of February and May might be collected, and thence be enabled to expand their beauties with vigor. (Flor. Man. v. 25.)
6102. According to Nicol, "the most proper situation for the greenhouse and conservatory, in an extensive and well laid out place, is certainly in the shrubbery or flower-garden; and not, as they are very generally to be found, in the kitchen-garden, combined with the forcing-houses. In smaller places, no doubt, they must be situated so as to suit other conveniences; and we often find them connected with the dwelling-house. In this latter way they may be very convenient, especially in the winter season, and may answer for keeping many of the hardy kinds of exotics; but it is seldom they can be so placed and constructed, on account of their constant need of the protection, and the culture of the finer sorts, and bring them to a flowering state. Such may rather be termed green-rooms, as being connected with the house." (Kal. 539.)

6103 Abercrombie says, "A greenhouse may be made a very ornamental object as a structure; its situation is, therefore, usually in a conspicuous part of the pleasure-ground, contiguous to the family residence. The front of the building should stand directly to the south, and the ends have an open aspect to the east and west." (Pract. Gard. 557.)

6104. Flower-nursery, and pits for forcing flowers. To every complete flower-garden and shrubbery, a piece of ground should be set apart in a convenient and concealed situation, as a reserve-ground, or nursery of flowering plants and shrubs. The situation should, if practicable, be behind and near to the range of hot-houses, and it may at the same time include the pits for forcing flowers, and the hot-bed department of the flower-garden. Here plants may be originated from seed, cuttings, pipings, and a proper stock kept up, partly in beds and partly in pots, for more easy removal, to supply blanks, and in the more select scenes, to replace such as have done flowering. No flower-garden can be kept in complete order without a nursery of this description; nor could the management of some sorts of florists' flowers, as the auricula, during the latter part of summer and winter, the carnation, &c. be well carried on without it. Here they may be grown, and, when in bloom, exhibited in proper stages in the main garden.

6105. Walks. In most styles of parterres these are formed of gravel; but in the modern sort (fig. 549.), which consist of turf, varied by wavy dug beds (1 and 2), and surrounded by shrubbery, they are sometimes dispensed with.

Such a flower-garden is recommended by the author of the Florist's Manual, as suitable for the "midst of pleasure-ground," and the beds "peculiarly adapted to the advantageous exhibition of flowers." The general length of the beds she recommends to be from twenty-three to twenty-five feet, and the width in the broadest part, about four feet; the grass to be five or six feet wide between the beds, that it may be conveniently mown and rolled; all the beds a good deal raised, and a tree (3) placed at the entrance (4) of light and rather pendulous foliage, and pruned to form a high stem. "If the space of grass between the borders appear too great, it may be lessened by baskets of ever-blowing roses, carnations, or any other plants; and these baskets may be formed by circular beds, surrounded by cast-iron, made to resemble the open edges of a basket, and painted of a very dark-green color." (p. 6.)

6106. In extensive and irregular parterres, one gravel-walk, accompanied by broad margins of turf, to serve as walks by such as prefer that material, should be so contrived as to form a tour for the display of the whole garden. There should also be other secondary interesting walks of the same width, of gravel and smaller walks for displaying particular details. The main walk, however, ought to be easily distinguishable from the others by its broad margins of fine turf. In general the gravel is of uniform breadth in the whole length of the walk; but in that sort of French parterres which they call parterres of embroidery (fig. 550.), the breadth of the gravelled part (a) varies like that of the turf. Such figures, when correctly executed, carefully planted, judiciously intermixed with basket-work, shells, party-colored gravels, &c. and kept in perfect order, are highly ornamental; but very few gardeners enter into the spirit of this department of their art. The French and Dutch have long greatly excelled us in the formation of small gardens, and the display of flowers; and whoever wishes
Book II.

PLANTING THE FLOWER-GARDEN.

797
to succeed in this department ought to visit Amsterdam, Antwerp, Brussels, and Paris; and consult the old French works of Mallet, Boyceau, Le Blond, &c.

6107. Edgings. In parterres where turf is not used as a ground or basis out of which to cut the beds and walks, the gravel of the latter is parted from the dug ground of the former by edgings or rows of low-growing plants, as in the kitchen-garden. Various plants have been used for this purpose; but, as Neill observes, the best for extensive use is the dwarfish Dutch box, kept low and free from blanks. Abercrombie says, "Thrift is the neatest small evergreen next to box. In other parts, the daisy, pink, London-pride, primrose, violet, and periwinkle, may be employed as edgings. The strawberry, with the runners cut in close during summer, will also have a good effect; the wood-strawberry is suitable under the spreading shade of trees. Lastly, the limits between the gravel-walks and the dugged-work may sometimes be marked by running verges of grass kept close and neat. Whatever edgings are employed, they should be formed previous to laying the gravel."

6108. Basket-edgings. Small groups near the eye, and whether on grass or gravel, may be very neatly enclosed by a worked fence of basket-willows from six inches to a foot high. These wicker-work frames may be used with or without verdant edgings; they give a finished and enriched appearance to highly polished scenery; enhance the value of what is within, and help to keep off small dogs, children, &c. Abercrombie scarcely approves of them. He says, "Where round or oval parterres stand on a ground of lawn, it is a prevailing fashion to surround them with what are termed baskets. These are commonly made either of wood or cast-iron; those of the latter material of course are durable; and the others, if painted, and removed under shelter in winter, will last ten or twelve years. Novelty is all attractive; and when men have walked as far as they can in the path of nature for principles of embellishment, for the sake of novelty they will walk back again. A bed of flowers and shrubs within a basket looks very much like a large bouquet. What is artificial, should have some use. Where cattle are to be kept off, a basket is serviceable." (Pr. Gard. 454.)

6109. To assist in the invention of figures for flower-gardens, the simple but ingenious contrivance (fig. 551.) invented by Professor Bradley may be made use of. It consists of two plates of looking-glass, of any convenient size, furnished with wooden backs, so as to admit of their being hinged (a). One part of a circular figure being then drawn on paper (b, c), the frames are to be opened the width of the figure (b, c, d), and placed on edge so as to include it, when the form will then be so multiplied by the looking-glass as to complete the circle. The kaleidoscope may also be resorted to, of which this instrument of Bradley's is supposed to be the origin or prototype.

CHAP. II.

Of Planting the Flower-garden.

6110. The manner of planting the herbaceous plants and shrubs in a flower-garden depends jointly on the style and extent of the scene. With a view to planting, they may be
divided into three classes, which classes are independently altogether of the style in which they are laid out. The first class is the general or mingled flower-garden, in which is displayed a mixture of flowers with or without flowering-shrubs according to its size. The object in this class is to mix the plants, as that every part of the garden may present a gay assemblage of flowers of different colors during the whole season. The second class is the select flower-garden, in which the object is limited to the cultivation of particular kinds of plants; as, florists’ flowers, American plants, annuals, bulbs, &c. Sometimes two or more classes are included in one garden, as bulbs and annuals; but, in general, the best effect is produced by limiting the object to one class only. The third class is the changeable flower-garden, in which all the plants are kept in pots, and reared in a flower-nursery or reserve-ground. As soon as they begin to flower, they are plunged in the borders of the flower-garden, and, whenever they show symptoms of decay, removed, to be replaced by others from the same source. This is obviously the most complete mode of any for a display of flowers, as the beauties of both the general and particular gardens may be combined without presenting blanks, or losing the fine effect of assemblages of varieties of the same species; as of hyacinth, pink, dahlia, chrysanthemum, &c. The fourth class is the botanic flower-garden, in which the plants are arranged with reference to botanical study, or at least not in any way that has for its main object a rich display of blossoms. On each of these gardens, or manners of arranging plants grown for their beauty or curiosity, we shall offer some remarks.

6111. The mingled flower-garden, or border, is by far the most common; it is what every gardener attempts at in planting his flower-borders, and the aim of the greater number of such as form parterres, or separate scenes for the culture of flowers, seldom goes further. The object here is to display a gay assemblage of colors during the season of flowers, without much regard to variety of form or diversity of character in these flowers, or the plants that produce them. The great art, therefore, in this kind of flower-border, is to employ such plants as produce large heads, or masses of flowers; to plant an equal number of every color, and such a variety in regard to time of flowering as may afford some of every color in flower from February to October. This object does not require a great variety so much as a judicious selection; for, supposing the number four to include all the colors of flowers, and one sort to continue in bloom a month, then for nine months of the year, viz. from February to October inclusive, only thirty-six sorts will be requisite to commence, as it were, the pattern of the border. Much more may be effected by a few sorts than by a great number, for the greater the number of sorts introduced in the pattern above thirty-six, supposing it correct that one sort continues in bloom a month, the greater the blank spaces that must remain between the plants in bloom. A moderate number of select sorts, or of what are called border-flowers, and that number selected equally from the different colors, and the sorts in bloom for nine months of blooming season, is what demands the exclusive attention of whoever would plant a mingled border, or flower-garden.

It has been frequently observed that flower-gardens have been on the decline for the last half century; and the cause of this appears to have been the influx of new plants during that period, by which gardeners have been induced without due consideration to be more solicitous about rarity and variety, than well disposed colors and quantity. The same error, and from the same cause, has prevailed, during the above period, in the planting of shruberies and tree-plantations.

6112. Abercrombie, Nicol, and other practical gardeners, seem to have no distinct ideas on the subject of arranging flowers in flower-gardens; but the authors of Hints on laying out Gardens, and of the Florist’s Manual, have viewed the subject in its proper light. Nicol says, as a judicious observation on the subject, ‘’the plants are arranged in mingled flower-borders, partly according to their size, and partly according to color. The tallest are planted in the back part, those of middling size occupy the centre, and those of humble growth are placed in front. The beauty of a flower-border, when in bloom, depends very much on the tasteful disposition of the plants in regard to color. By intermingling plants which flower in succession, the beauty of the border may be prolonged for some weeks. In a botanic-garden the same plant cannot with propriety be repeated in the same border; but in the common flower-garden a plant, if desired ornamental, may be repeated with the best effect; when more than a few are repeated, and seen in succession, these flowers will not be distinguished by new combinations, and may take the place of species of which there are very few; and it is as easy to distinguish the combinations of few species, as it is to see many plants of double scarlet lychins, double sweet-william, or double purple japonica.’’ (Ed. Encyc. art. Hort.)

6112. The author of Hints, &c. remarks ‘’that the beauty of parterres depends more on the materials with which they are planted than on their form; and that the prevailing error consists in crowding them with all sorts of trees and plants at random, or filling them entirely with rare species, which will ever want one principal source of beauty—health.’’ In the Florist’s Manual it is observed, that ‘’the fastidious man who has stored his house from the choicest colors from the most refined gardeners, will have, in his collection of rare species; who has procured innumerable rose-trees, chiefly consisting of old and common sorts, brought into notice by new nomenclature; who has set apart a portion of ground for American plants, and planted the same as are the most proper to his bog, soil, with the greatest number of sorts. When it is, however, that the most attentive observer, when, instead of the brilliant glow of her more humble neighbor’s parterre, she finds her own distinguished only by paucity of color, and fruitless expenditure. Variety of species, bog borders, and largely lettered pegs, are all good in their way, but they will not produce a gay flower-garden; and the simple cause of this error is in this: the florist is the artist and patron. He must have the art of procuring to well blended quantity; as, without the frequent repetition of the same plant, it will be in vain to attempt a brilliant flower-garden, and, as in the judicious mixture of every common color, the art of procuring it consists. Hence, the foundation thus laid, the solicitude of those who wish to complete the superstructure must not be for rare species, but for new color, so that the commonest primula which presents a fresh shade of red, blue, yellow, &c. ought to be esteemed more valuable than the most rare American plant which does not bring a similar advantage. In the formation of that assemblage of
flowers, which may be distinguished by the term of 'The Mingled Flower-Garden,' it is essential that the separate parts should, in their appearance, constitute a whole; and this appearance is not incompatible with some other ways of seeking for the perfection of the result in its manner of planting. In some gardens this appearance of a whole is entirely destroyed by the injudicious taste of setting apart distinct borders for pinks, hepaticas, primulas, or any other favorite kinds of flowers; also for different evergreens, hyacinths, &c., these distinct borders, although beautiful in themselves, break that whole which should always be presented to the eye by the mingled flower-garden, as single beds, containing one species only, form a blank before that species produces its flowers, and a mass of decaying leaves when the glow of their petals is no more. The reverse of this may be seen in the bordering of the front of the Harrow-road. Here there should be, at least, two of every species; but the precise number must be regulated by the force of color displayed by the plant, and the size and the relative position of the borders. It will be only necessary to make a system of interchange between them that the eye should not be checked by the failure, in any part of it, of the prevalent colors of the season." (p. 5.)

6114 Hogg, who may be considered an unprejudiced observer of the different tastes in disposing of flowers, has the following remarks: "We are apt to ridicule the Dutchman, as well as the imitators of him here at home, who divide their gardens into small beds, or compartments, planting each with separate and distinct flowers: we ridicule the plan, because it exhibits too great a sameness and formality; like unto the nosegay that is composed of one sort of flowers only, however sweet and beautiful they may be, they lose the power to please, because they want variety. It must undoubtedly be acknowledged, that a parterre, no matter in what form, whether circular or square, elliptical or oblong, with its shrubs, plants, and flowers in it, like the flowers of a tastefully arranged bouquet, are variously disposed in neat and regulated order, according to their height and color, is a delightful spectacle, and worthy of general imitation. Yet still in some particular cases I am disposed to copy the Dutchman, and I would have my bed of hycainths distinct, my tulips distinct, my anemicies, my ranunculuses, my pinks, my carnations distinct, and even my beds of hollyhocks, double blue violets, and dwarf-Larkspurs distinct, to say nothing of hedge-rows of different sorts of roses. Independent of the less trouble you have in cultivating them here kept separate, you have beauty in masses, and you have likewise their fragrance and perfume so concentrated, that they are not lost in air, but powerfully inhaled when you approach them. Mrs. Siddons, the celebrated tragic actress, is a great admirer of this mode of planting, and fond of contemplating this 'beauty in masses.' She adopted this style of gardering at her late residence on the Harrow-road. Her favorite flower was the viola amena, the common purple heart's-ease, and this she set with unsparing profusion all around her garden. Her garden was remarkable in another respect, and might with great propriety be styled a garden of evergreens, which, together with a few deciduous shrubs, made a most tasteful and permanent effect. Any cast, in fact, both crimson, yellow, arbor-vita, holly, cypress, the red cedar, laurel, Irish ivy, bay-tree, arbutus, spurge-laurel, &c. The only part of the year in which it could be viewed with any degree of satisfaction was the winter, as giving rise to a pleasing assemblage of ideas in beholding the firm ground and setting, at a time when the rest of the surrounding trees were stript naked and bare." (Tr. on Flowers, 69.)

6115 To give an example of the manner of planting a bed or border in the mingled style, suppose the various colors of flowers to be all included under the four common colors, red, white, blue, and yellow; that for the time of blooming, we allow February and March as one division, March and April as a second, May and June as a third, July as a fourth, August as a fifth, and September and October as the sixth and last. Then suppose the border, or bed admits of four rows in width; the lowest plants to be placed next the walk, or the eye of the spectator, and the tallest at the back in regular gradation. Mark out the border in rows long enough way to be kept separate, you have beauty in masses, and you have likewise their fragrance and perfume so concentrated, that they are not lost in air, but powerfully inhaled when you approach them. Then begin at the first row (fig. 552. a), and fix on the order in which the plants are to be placed as respects their time of flowering. To distribute the plants in flower at one time as equally as possible, the order of the colored plants in your borders, as 3, 5, 2, 4, will, I believe, be found the best. Next fix as to the order of colors; and here it is of little consequence what order is fixed on, provided that order be maintained throughout the border: say that we adopt the order of red, white, blue, and yellow; then the first row to be of the lowest plants will stand thus: 1r. 6w. 3b. 5y. 2r. 4w.; that is, a red flower to come into bloom in February and March; next to it, a white flower to come into bloom in September and October; next, a blue flower to come into bloom in May and June; then a yellow flower to come into bloom in August; then a red flower to come into bloom in April and May; and lastly, a white flower to come into bloom in April and May. The species of red, white, blue, and yellow flowers are given in the following way, however, not begin with the same month and color for the sake of more effectually mingling the times of flowering and color of the flowers. Where roses or other shrubs are to be introduced, a plant must be omitted, which, however, should not be allowed to derange the order of the rest.

6116. If a double border, with a walk on each side (fig. 552. a to h) to a bed-group, or compartment on a lawn, to be viewed on all sides, is to be planted, then it is only necessary to fix on the number of rows, and to keep the lowest plants in the margin and the tallest in the centre, adhering to the rows, to the order of time, and of colors given above, or to any order that may be fixed on, and inserting shrubs in like manner where it may be deemed necessary.

6117. Flowers in borders should always be planted in rows, or in some regular form, and that appearance should be assiduously kept up by trimming off all irregular side-shoots and straggling stalks, and reducing the bulk of plants which grow too fast. Every approach to irregularity and a wild, confused appearance should be avoided. Let the border be a line of beauty, not a chaos of disorder.

6118. With four colors, four sizes, and six times of coming into flower, a mingled border may be commenced with ninety-six sorts; and the pattern may be repeated like the border of any work of art ad infinitum; but it is also evident, that it may include any number of species, provided these have the requisite degrees of height, color, and time of flowering; the second and every successive repetition of the pattern being made up of different, and not before-introduced species, but still of the heights, colors, and times of flowering required for the first example of the pattern. The safest way, however, as we have
already observed, is to adopt but a moderate number of species, and those of the showy sorts that have numerous varieties, and are of hardy vigorous growth. A suitable list for this purpose is given in the floricultural catalogue, under the head of "Border Flowers," and the reader may increase it at pleasure from the "Prodromus of Page."

6119. The select flower-garden being limited to one kind, or class, of plants, is comparatively simple as far as respects planting. It may be devoted to florists' flowers, as the hyacinth, tulip, pink, auricula, &c.; to select flowers, as the dahlia, peony, chrysanthemum, &c.; to annuals, hardy, half hardy, and tender; to American or bog-earth shrubs and plants; to any one natural order, as the bulbous-rooted tribe; or to spring, summer, or autumn flowers, &c.

6120. Florists' flowers and select flowers are planted in beds or compartments of carefully prepared soil, and the arrangement in the beds is generally conducted on the principle of mixing the colors and shades of colors. As the same species is generally of the same color and size, and come into flower at the same time, no particular attention is requisite in these respects. (See Hyacinth and Auricula, in the catalogue.)

6121. A manner of arranging annuals, as well as different sorts generally come into flower about the same time, may either be arranged according to their colors and heights jointly; or, as there are numerous varieties of some sorts, as of larkspur, chrysanthemum, lupin, &c., each species with its varieties may be sown in groups or beds, by itself; and the general principle by which to determine the sorts which are to join each other, may be general classification of all the flowers generally admitted during the season, arranged according to the Jussieu classification (589.), will be found a convenient guide.

6122. An American garden combines shrubs and even low trees. These may be arranged in the mixed method, according to color, height, and time of flowering, the trees and shrubs alone, or both combined; but the most suitable way is to follow the natural orders, attending, at the same time, to keep the higher sorts farthest from the walk or side from which the group or border is to be chiefly viewed. This arrangement has an excellent effect in an American shrubbery, where the low species of heaths and other bog under-shrubs which are introduced, supply the place of herbaceous plants.

6153. A garden exclusively devoted to bulbous-rooted flowers, admits of being very perfectly arranged after the natural order of things, so natural an order is the result of the arrangements. Assumptions be both of foliage and flowers than, the Phanerogameae. It would require very little nicety beyond introducing the proper genera and species in succession, taking care to keep the taller bulbs, as lilium, fritillaria, &c. in the interior of the groups or beds.

6123. Gardens of spring, summer, or autumn flowers may be planted on any of the principles that have been mentioned.

6125. The changeable flower-garden. The essential principle of this garden consists in the power of changing its productions at pleasure, so that whenever any plant, or group of plants, begin to decay, they can be removed and their places supplied by others coming into bloom. To this end this a large nursery is requisite, in which the plants must be kept in pots, and removed and plunged in the borders as wanted. The Chinese, Sir W. Chambers informs us (Dissert. on Oriental Gard. 56), excels in this mode of gardening, and they who have been in some of their gardens, as in a traveller who has been in the known a mandarin (or noble) have the whole furniture and style of his parterre changed in a single night, so as next morning to present not only a different description of flowers, shrubs, and dwarf trees, but a different arrangement of the beds and compartments. Something of the same kind is practised in the gardens of the Tulleries and all those of the Imperial gardens at Petersburg, and in the vice-royal gardens at Monza. Gardens of this description admit of a very perfect arrangement of the flowers, whether in the mingled manner, in select groups, or according to the natural method. It is only with such resources that a flower-gardener can "paint his way," as Sir W. Chambers says the Chinese artists do, "not scattering their flowers indiscriminately about their borders, but disposing of them with great circumlocution along the skirts of the plantations, or other places where flowers are to be introduced. They reject all that are of a straggling growth, of harsh colors, and poor foliage, choosing only such as are of a beautiful growth, low either in small collections or in clusters, are of beautiful forms, well leaved, and of tints that harmonise with the greens that surround them. They avoid all sudden transitions, both with regard to dimension and color, rising gradually from the smallest flowers to the hollyhocks, poppies, sun-flowers, carnation-poppies, and others of the same kind, varying their large flowers, gradations, from white, yellow, scarlet, red, purple, and incarnate, to the deepest blues, and most brilliant crimsons and purples. They frequently blend several roots together, whose leaves and flowers unite, and compose one rich harmonious mass; such as the white and purple candytuf, larkspurs, and mallows of various colors, double poppies, hollyhocks, pinks, and carnations; with many more of which the forms and colors combine with each other; and the same method they use with flowering shrubs, blending white, red, and variegated roses together, purple and white lilacs, yellow and white jessamine, altheas of various sorts, and as many others as they can with any propriety unite. By these mixtures they increase considerably the variety of their color parts; in some of their larger estates they calculate on a thousand species in the natural ground; but in flower-gardens, and all other parts that are highly kept, they are in pots, buried in the ground, which, as fast as the bloom goes off, are removed, and others are bought to supply their places; so that constant change is almost a necessity for almost the year; and the flowers are never seen but in the height of their beauty." (Dis. on Orient. Gard. 96.)

6126. The botanic flower-garden being intended to display something of the extent and variety of the vegetable kingdom, as well as its resemblances and differences, should obviously be arranged according to some system or method of study. In modern times, the choice is almost limited to the artificial system of Linneus, and the natural method of Jussieu, though Adanson has given above fifty-six different methods by which plants may be arranged. (Fam. des Plants.) The latter has much the best effect in a garden, and corresponds better with culture. The former, though most convenient for the young student, yet by bringing plants together that have few or no obvious relations, it destroys that harmony which is so gratifying in viewing natural subjects. Whatever method is adopted, the plants may either be placed in regular rows, or each order may be grouped apart, and surrounded by turf or gravel. For a private botanic garden, the mode of grouping on turf is much the most elegant, and it has this advantage, that as the species belonging to the group are increased, it can be enlarged by appropriating a part of the turf, and any group containing few species may be filled up with repetitions for effect. The groups may be of the most irregular outlines, and those which are to contain trees may be raised or lowered in surface, according to the species may be natives of hills or
valleys, and the trees and plants so dispersed as that the former shall not conceal the latter, nor present a compact lumpish appearance at the edges, or in the outline against the sky. Rock-work may be introduced in groups where there are many alpines to be grown; and bogs, ponds, and springs imitated in others destined for aquatics, &c. as far as consistent with botanical purposes. A gravel-walk may be so contrived as to form a tour of all the groups (fig. 553.), displaying them on both sides; in the centre, or in any fitting part of the scene, the botanic hot-houses may be placed; and the whole might be surrounded with a sloping phalanx of evergreen plants, shrubs, and trees. The plants in such a garden should generally be neatly, but inconspicuously named, or, at all events, numbered; but naming is greatly to be preferred, as saving trouble to the spectator, and more inviting to the novice desirous of knowledge. It is hardly necessary to observe that the above modes, or others that we have mentioned, of planting a flower-garden, are alike applicable to every form or style of laying out the garden or parterre, and that they do not interfere with any mode of enclosing or surrounding it, or of edging the walks.

6127. Decorations. It is usual to employ different objects of art as decorations to flower-gardens, and the practice is founded in reason, since the works of nature and of art lend force to each other by their contrast. We have, in a former part (1805. to 1846.), enumerated the principal garden-decorations. Those more especially applicable to the flower-garden are the fountain in various forms; the open and covered, or rustic seat (fig. 555.); the statue (fig. 554.) in all its varieties of them, bust, single figure and group, and in the various materials of stone, metal, or verdure; the arbor, and a variety of others. Even the apiary and aviary, or, at least, here and there a beehive, or a cage suspended
from a tree, will form very appropriate ornaments. Sometimes inoffensive birds, as the sea-gull, may be introduced to run at large; gold-fish are very appropriate in the aquarium; and an animal which affords great amusement by its cry and song in the flower-gardens of the south of Germany, the tree-frog (Rana arborea), would be an acquisition in this country. In some families there is a taste for minerals or antiquities; and here, besides larger specimens distributed in the garden, a building (fig. 556.) may be introduced, combining a mineral cabinet (a), an aviary (b), and the botanic hot-houses (c).

6128. Where the old French style (figs. 545, 550.) is imitated, a profusion of marble and vegetable sculptures, verandah arcades, colonnades, arbors, &c. are in character; but in the more simple and modern forms (figs. 540, 541, 543.) a few stools, sofa-chairs, a pavilion-seat (fig. 538.), a sun-dial, fountain, some urns, and a few good statues, will, in most cases, be sufficient. In the distribution of even these few decorations much judgment is requisite to avoid exciting ridicule by falling into the vapid, the flippant, or some other species of deformity. (See Schimmelpenninck on Beauty, &c.)

6129. Time of planting herbaceous plants. This is, in general, autumn and spring; but any perennial plant may be safely removed after it has done flowering or produced seed. With respect to biennials and annuals, they may be planted at almost any season before they have begun to throw up flower-stems. Biennials, however, are generally sown early in autumn in the flower-garden nursery, and transplanted either late in the same season or early in the following spring, to where they are to flower. Annuals are commonly sown in spring, where they are finally to remain. The culture of herbaceous flowers of the more valued sorts is exceedingly varied, and will be found under each species or class in the Flower-garden Catalogue. For the preparation of the soil and the manner of performing the operation, see these articles in (Chap. IV.) Planting the Shrubbery.

Chap. III.

Of Forming the Shrubbery.

6130. By a shrubbery, or shrub-garden, we understand a scene for the display of shrubs valued for their beauty or fragrance, combining such trees as are considered chiefly ornamental, and some herbaceous flowers. The form or plan of the modern shrubbery is generally a winding border, or strip of irregular width, accompanied by a walk, near to which it commences with the herbaceous plants and lowest shrubs, and as it falls back, the shrubs rise in gradation and terminate in the ornamental trees, also similarly graduated. Sometimes a border of shrubbery accompanies the walk on both sides; at other times only on one side, while the other side is, in some cases, a border for culinary vegetables surrounding the kitchen-garden, but most generally it is an accompanying breadth of turf, varied by occasional groups of trees and plants, or decorations, and with the border, forms what is called pleasure-ground.

6131. The sort of shrubbery formed under the geometric style of gardening (fig. 551.) was more compact; it was called a bouque, thicket or wood, and contained various compartments of turf or gravel branching from the walks, and very generally a labyrinth. The species of shrubs in those times being very limited, the object was more walks for recreation, shelter, shade and verdure, than a display of flowering shrubs. What was wanting in natural beauty and variety, however, was made up by the art of the gardener in cutting such trees and shrubs as he had, into curious shapes. Shrubberies are often made for the sake of obtaining an agreeable walk to some particular place or scene, as the kitchen-garden, farm, wood, &c.; and sometimes in order to lead the spectator to different points, where views or distant prospects may be obtained. The most desirable shrubbery is one where both these objects are combined; and the least so, where the walk leads to no particular object, is shut up on both sides, and has no beauties to depend on but those of the shrubs. Hence Sir W. Chambers complains of walks en cul de sac, and Knight of "the shrubbery's insipid scenes," &c. (Tr. on Country Res. 1. 352.) The shrubbery, however, judiciously laid out and planted, will always be a scene of considerable beauty and use about a country-seat. It is one of the principal resources for a home-walk for exercise; and as Repton has observed, a tolerable walk, even round one's own field, is more interesting than a better one where we have no interest. "We are greatly indebted to shrubs," Nicol observes, "for much of the pleasure and delight we enjoy in our gardens. Though they produce no eatable fruits, nor afford us any sort of nourishment, yet they are particularly conducive to our comfort. In winter, they shelter us in our walks; in summer, they shade us from the sun. They afford a great variety of flowers, a varied foliage, and are standard ornaments that give us no great trouble. They are particularly useful in the character of screens, whether against the weather, or to hide disagreeable objects, in which case they may be planted nearer to the house than forest-trees. When planted in masses at a distance, they become agreeable objects, and often improve the scenery of a place. The shrubbery is often a matter of utility as well as of ornament, in which case it gives the highest satisfaction. When formed for the purposes of shutting out the offices or the kitchen-garden from the view of the house; for sheltering the latter or the garden, or for connecting the house with the garden and the orchard, the shrubbery becomes useful and interesting."

6132. In respect to situation, it is essential that the shrubbery should commence either
immediately at the house, or be joined to it by the flower-garden; a secondary requisite is, that however far, or in whatever direction it be continued, the walk be so contrived as to prevent the necessity of going to and returning from the principal points to which it leads over the same ground: but as this is a matter which must be arranged in the general disposition or laying out of the residence, it need not be here entered on.

613. The extent of the modern shrubbery must depend more on the extent of that place of which it is a part than on any other principle, and it is, or ought to be, so blended with the flower-garden lawn, as scarcely to admit of its quantity being estimated apart. Where the proportion of pleasure-ground, which may be judiciously apportioned to a residence, depends so much on the ground’s surface, and on the character or style of the whole seat, nothing definite can be laid down in the way of rules. The walks in the pleasure-ground should generally exceed a mile or two for the sake of recreation; but what proportion of these should be in open lawn, and what in flower-garden, or along the margin of a shrubbery, is too vague a question to receive any useful answer. Local circumstances and the character to be created must determine every thing. It may be mentioned as a characteristic distinction between the ancient and modern shrubbery, that the former was of limited extent, compact form, situated near the house, and that the length of walk was made up by repetition of parallel and cross walks. The whole of these had little distant prospect, and were generally more sheltered and shaded than is suitable for our climate; whereas, in the modern shrubbery, the length is made up by stretching out the walk to a distance; and air and ventilation, as well as views and prospects, are obtained by its being planted chiefly on one side. Such shelter and shade as is deemed requisite for the walk is obtained by the introduction of scattered trees along its open margin.

6134. Soil. “Shrubs, in general,” Nicol observes, “thrive very well in ordinary garden-land, and better in light than in heavy soils. Most shrubs, likewise, do well in ground a foot in depth; but it is always advisable to trench to the full depth of the soil, previous to planting, if that were even two feet. Manure is seldom bestowed on shrubs, and if the soil be not far below mediocrity, it is seldom necessary, provided the ground be otherwise well prepared, and be meiliorated by trenching or digging. In the case of planting screens, where it is desirable to have them effectual as soon as possible, or in planting favorite shrubs in particular situations, every justice should be done to the soil in preparing and enriching it, either with manure or by the addition of fresh earth. Those who are curious in collections of certain shrubs, prepare or choose certain soils for them. Evergreens, for the most part, thrive well in loam of a middling texture; but some kinds do better in mossy humid earth, as the azalea and rhododendron. Deciduous shrubs, in general, thrive well in light loams or sandy soils; but certain kinds flower better in rich mellow earth, as the moss-rose and the robinia.”

6135. Walks. “The conducting of walks,” Nicol says, “through the shrubbery, is a matter both of conveniency and of taste: of conveniency, when the shrubbery is merely a passage from one place to another, or a narrow screen to the garden. In the former case, the walk should be simple and direct: in the latter case it may be circuitous; and if there be any variety in the ground, it ought to lead to particular points of view. The walks, however, should seldom cross one another; they should rather take off at oblique angles; nor should one run parallel to another within view. It is proper to show off the shrubs, but too many walks perplex. Their breadths may be various. If short, they should be narrow; if long, and if a considerable reach be caught at once, they should be broad. A medium may be taken at five feet, the extremes being three and eight. They may be of turf or of gravel, but the latter is always most wholesome, and most agreeable in winter.” In the ancient style, where the shrubbery, or unbranched scene (fig. 557. a), often enclosed the flower-garden (b), both being situated in front of the house (c), the walks (d) were laid out in arbitrary geometrical shapes, crowded and numerous, to afford sufficient space for recreation, and varied by niches (e), boudoirs (f), saloons (g), and other open parts to give variety.

6136. Fence. Local circumstances must, in almost every case, determine the sort of exterior or boundary-fence most proper for the shrubbery or pleasure-ground; the interior, or that on the open side, should, in almost every case, be one of the inconspicuous kind; either light iron-raftings, moveable hurdles of wood or iron, or the sunk-fence. Where the shrubbery is not a boundary plantation, a light fence may include it on both sides; but so much depends on locality and other arrangements, that the subject cannot be profitably discussed separately from that of laying out the entire residence. Under the geometric style, the business of fencing the shrubbery or woody scene, was very simple, the whole being generally surrounded by a high wall. “Fences of all kinds,” Abercrombie observes, “are rather necessary and useful as instruments of shelter and security than to be chosen as materials of ornament. Whether the view terminates on the fence, or is directed beyond it, the effect on the scene, at best, is negative; thus, a fence is sometimes made higher than its proper use requires, merely to shut out something more unsightly; and, in judiciously employing that capital invention, the sunk-fence or
ha-ha, the advantage, though great, is purely negative; some prospect worth retaining at considerable cost is not obstructed.”

6137. Reserve-ground for the shrubbery. A plot of ground should be set apart for the propagation and culture of the more tender shrubs, to supply deaths or accidents in the front of the shrub-border. This reserve-nursery will be most conveniently situated when joined to that of the flower-garden; but it may also be taken from the interior of any wide part of the plantation where it will not be seen. Here roses, mezereons, American shrubs, honeysuckles, and a variety of the more ornamental and tender sorts should always be in readiness, partly in pots and partly in nursery lines, to remove to the principal scene, either to add to its usual beauty, or to compensate for accidental defects. To the same ground may be added a space for accumulating leaves, spray, and other refuse of the shrubbery, to ferment and produce manure for the nursery in the same way as is done in the compost-grounds of the kitchen and flower garden.

CHAP. IV.

Of Planting the Shrubbery.

6138. On planting the shrubbery the same general remarks, submitted as introductory to planting the flower-garden, are applicable; and shrubs may be arranged in as many different manners as flowers. Trees, however, are permanent and conspicuous objects, and consequently produce an effect during winter, when the greater number of herbaceous plants are scarcely visible. This is more especially the case with that class called evergreens, which, according as they are employed or omitted, produce the greatest difference in the winter aspect of the shrubbery. We shall here describe four leading modes for the arrangement of the shrubbery, distinguishing them by the names of the mingled or common, the select or grouped manner, and the systematic or methodical style of planting. Before proceeding farther it is requisite to observe, that the proportion of evergreen trees to deciduous trees in cultivation in this country, is as 1 to 12; of evergreen shrubs to deciduous shrubs, exclusive of climbers and creepers but including roses, as 4 to 8; that the time of the flowering of trees and shrubs is from March to August inclusive, and that the colors of the flowers are the same as in herbaceous plants. These data will serve as guides for the selection of species and varieties for the different modes of arrangement, but more especially for the mingled manner.

6139. To dispose shrubs and trees in the mingled manner, proceed as under. The width of the space to be covered with trees, shrubs, and flowers being given, first mark it out in rows lengthways. The first
row may be two feet from the margin of the turf or the edge of the walk; the second, three feet from the first; the third, four feet from the second; and so on to the back of the plantation. Suppose the width to admit of rows (fig. 558, a to k), then the six rows next the walk will occupy a space of twenty-seven feet, which may be devoted to shrubs, and the remaining three rows will occupy a space of thirty-seven feet, and may be planted with trees. Then beginning with the first row, which is destined for the lowest class of shrubs, arrange them according to the times of their flowering, which will, as in arranging herbaceous plants, be most conveniently done at six times: viz. 1, March; 2, April, &c. to 6, August; and they will stand as in the flower-border in the order of 1, 6, 3, 5, 2, 4, and with the colors in the same manner (a). The second row (b) is to be arranged in the same manner; and as trees, though nearly of the same size when planted, yet attain finally very different degrees of bulk, provision must be made for the plants in each row to expand year after year, till they attain their full growth. This we propose to do by planting two plants of a sort in the second row (b), three in the third, and so on (as indicated in the figure), till in the last or tenth row (k), there will be ten plants of a sort in a line together. It is to be observed, that a deciduous and an evergreen sort (marked d, e, in the figure) are to be planted alternately, in order to ensure an equal mixture in respect to verdure; and that the colors (denoted by r, w, g, y, in the figure) are mixed in as the mingled border, to ensure a general display of mixed blossoms. The second or third year such of the plants are to be thinned out as crowed the others, reserving, however, as final plants, one of each sort, (say E for the evergreens, and D for the deciduous sorts), so placed in respect to the plants in the other rows, as that the whole, when finally thinned out, may stand in quinuncx. The largest trees will then occupy about 100 square feet each; and each of the shrubs in the front row about a square yard; there will be the same number of deciduous plants as evergreens; some shrubs of all the four colors in blow throughout the whole season, and a verdant aspect in summer as well as winter.

558

..
6140. The distance between the rows of trees (ten feet) may in some cases be an objection, for a year or two at first; but this, we consider, will be more than counterbalanced by the opportunity afforded of cultivating the ground between them, and by the air and light admitted to their side shoots, which will the sooner fit them for producing blossoms. All formality of appearance will soon be done away by the irregular growth of the plants, and by the thinnings which must take place in, at the latest, three years after planting. If any, however, object to the appearance of rows, they may be obliterated, by introducing some plants in the intervals of the same sort as those in the lines adjoined; but in doing this, care must be taken never to lose sight of the shrub or tree which is finally to remain, as it is of importance to this plan, (which is not natural or picturesque planting), that the regular disposition of the whole be preserved, as well with a view to the gradation of height as to the mixture of color in the flower, and of permanent and deciduous foliage. The herbaceous plants only remain to be added. These are to be inserted one row in front of the first row of shrubs (o), and three or more rows (p, q, r, s) in the intervening spaces between the next rows. The plants are to form a quincunx with the shrubs; and the same arrangement as to height, color, and time of flowering, adopted as in the mingled border. Such a shrubbery may be commenced with (2 x 6) twelve sorts of evergreen, and the same number of deciduous trees; with (6 x 6) thirty-six sorts of shrubs, half the number deciduous, and half evergreen; and with (5 x 6) thirty sorts of herbaceous plants. It may then be continued either by repeating the pattern with the same sorts, or by other sorts; or principally by the same sorts, with some others occasionally. If a show of flowers is valued, the sorts employed must be comparatively few, as the flowers of the greater number of trees and shrubs are of dull colors, or little conspicuous. The evergreen trees, in a popular sense, can hardly be said to have any flower; but still a number of them must be introduced in the back rows, to blend with horse-chestnuts, limes, acacias, wild cherries, wild pears, &c. &c.

6141. The select or grouped manner of planting a shrubbery (fig. 559,) is analogous to the select manner of planting a flower-garden. Here one genus, species, or even variety, is planted by itself in considerable numbers, so as to produce a powerful effect. Thus the pine tribe, as trees, may be alone planted in one part of the shrubbery, and the holly, in its numerous varieties, as shrubs. After an extent of several yards, or hundreds of yards, have been occupied with these two genera, a third and fourth, say the evergreen fir tribe and the yew, may succeed, being gradually blended with them, and so on. A similar grouping is observed in the herbaceous plants inserted in the front of the plantation; and the arrangement of the whole as to height, is the same as in the mingled shrubbery.

6142. The chief difficulty in this manner of planting is so to select the sorts that are to succeed each other, so to blend one group or kind with those adjoining, and at the same time maintaining the requisite gradation from the front to the back of the plantation, as to preserve to the spectator in walking along, the appearance of a whole. When this is successfully accomplished, and on a large scale, no kind of shrubbery can be more beautiful in summer; but in winter it will present parts wholly without evergreens, and it will only be rich in flowers in some parts; as for example, where the roses, spirea, mespilus, &c. are introduced. By proper contrivance, however, the evergreens, the showy flowering deciduous kinds, and the less showy deciduous sorts may form three divisions, and the two former can be kept nearest the mansion. The best guides as to the sorts proper to adjourn each other, are the general form and mode of growth; and next, the color and foliage. In these particulars the transition should always be gradual. Thus, among the trees, the pines, cedars, firs, and yew, form a regular gradation, and the shrubs which may be placed near them are the arbor vitae, juniper, whin, &c. &c. To place groups of weeping-willow or elm adjoining the pines, and to select roses and lilacs as shrubs, would produce a harsh and incongruous effect. There is obviously much less natural affinity between herbaceous plants and shrubs than between shrubs and trees; but the groups of the herbaceous plants must harmonise among themselves on the same general principles as the trees; thus pink-looking plants (caryophyllaceae), should not be succeeded by coarse broad-leaved sorts (boraginaceae), but rather by more delicate kinds, as grasses or primrose, &c. There may sometimes also be a certain species of relation between the herbaceous plants and shrubs; thus the bulbous-rooted kinds, and small early flowers, as violets, primrose, will be more fitly planted among evergreens and early-flowering deciduous shrubs than among late deciduous kinds.
6143. Various other modes of select-planting shrubberies may be adopted; such as collecting together all such shrubs, trees, and flowers as flower at the same time, or have the same color of flower, or foliage, or the same odors, or the same general shape, or the same natural habitation, as of marshes, mountains, &c., or the same country, as America, Switzerland, Sweden, &c. But the intelligent gardener who has attended to what has been already advanced, can hardly require farther instructions to form such plantations. We would suggest, as worth trial, where there was ample space, the mode of arranging by colors; the ancients are said to have paid particular attention to this in mixing their trees. (Falconer, &c. and see 37.) Every one must have experienced a difference in this respect between walking in a pine-forest, a plantation of balsam-poplars, a birch-cope, and beside sweet- briar and juniper hedges. An arrangement of this kind, depending on the smell of the buds and leaves, rather than of the flower, would have its effect the greater part of the year, especially after showers.

6144. Systematic or methodical planting in shrubberies consists, as in flower-planting, in adopting the Linnaean or Jussieuan arrangement as a foundation, and combining at the same time a due attention to gradation of heights. This mode, executed on a grand scale, would unquestionably be the most interesting of all, even to general observers; but on a small scale it could not be so universally pleasing as the mingled manner, or the mode by select grouping. The uninstructed mind might be surprised and puzzled by such an assemblage; but not perceiving the relations which constitute its excellence, they would be less pleased than by a profusion of ordinary beauties; by a great show of gay flowers and foliage. Dr. Darwin is said to have blended picturesque beauty with scientific arrangement in a dingle at Litchfield, where he disposed of a large collection of trees and plants in the Linnaean manner. The same thing may be attempted on any description of surface, and with any form of ground-plan, provided turf be introduced, and care be taken to elongate the groups containing trees in such a way as to preserve a sufficient degree of woodiness throughout, both for shelter, shade, and picturesque effect. In this way we have arranged a spot (fig. 560.) of little more than an acre and a half, so as to ordinary observers, to be nothing more than a house surrounded by pleasure-ground, but to the botanist and painter, to be a scientific and picturesque scene. This spot combines a villa and offices (a), a kitchen-garden (b), reserve-garden and melonground (c), botanic ground for herbaceous plants (d), rock-work (e), rosarium (f), aquarium (g), American ground (k); besides a variety of other subordinate scenes, a scattered orchard (f), and the shrubbery (k), arranged in irregular, elongated groups on lawn, in the manner mentioned. But much the most interesting mode of arrangement would be that of Jussieu, by which a small villa of two or three acres might be raised, as far as gardening is concerned, to the ne plus ultra of interest and beauty. To aid in the formation of such scenes the tables (588, 589.) exhibiting the genera contained in each Linnaean or Jussieuan order, and also the number of species distributed according to their places in the garden, will be found of the greatest use.

6145. Chinese arrangement. It is only since the great influx of trees and shrubs from America, during the latter half of the last century, that the idea of arranging shrubs found a place in the writings on gardening. Sir W. Chambers seems to have been the first who suggested it in his account (whether correct or not, is of little consequence to our present purpose), of the practice of the Chinese gardeners. The Chinese, he says,
in their plantations, do not, as is the practice of some European gardeners, plant indiscriminately every thing that comes in their way; nor do they ignorantly imagine, that the whole perfection of plantations consists in the variety of the trees and shrubs of which they are composed: on the contrary, their practice is guided by many rules founded on reason and long observation, from which they seldom or never deviate. Many trees, shrubs, and flowers, they say, thrive best in low moist situations; many on hills and mountains: some require a rich soil; but others will grow on clay, in sand, or even upon rocks; and in the water: to some a sunny exposition is necessary; but for others, the shade is preferable. There are plants which thrive best in exposed situations; but, in general, shelter is requisite. The skilful gardener, to whom study and experience have taught these qualities, carefully attends to them in his operations; knowing that thereon depend the health and growth of his plants; and, consequently, the beauty of his plantations.

6146. The perfection of trees for ornamental gardening consists in their size, in the beauty and variety of their forms, the color and smoothness of their bark, the quantity, shape, and rich verdure of their foliage, with its early appearance in the spring, and long duration in the autumn; likewise in the quickness of their growth, and their hardness to endure the extremities of heat, cold, drought, or moisture; in their making no litter, during the spring or summer, by the fall of the blossom; and in the strength of their branches, to resist, unhurt, the violence of tempests.

6147. The perfection of shrubs consists not only in most of the above-mentioned particulars, but also in the beauty, durability, or long succession of their blossom; and in their fair appearance before the blossoms are open. Many of them, indeed, so please or charm the eye, that full good qualities; but choose such as have the fewest faults; and avoid all the exotics that vegetate with difficulty in our climate; for though they may be rare, they cannot be beautiful, being always in a sickly state.

6148. The excessive variety of which some European gardeners are so fond in their plantations, the Chinese particularly, is occasionally observed by the most learned botanists. Of that diversity, perhaps, arise the confusion, and destroy all the masses upon which effect and grandeur depend: they observe too, that it is unnatural; for, as in nature most plants sow their own seeds, whole forests are generally composed in the same sort of trees. They admit, however, of a moderate variety; but are by no means merciless in the choice of their plants; attending, with great care, to the color, form, and foliage of each; and only mixing together such as harmonise and assemble agreeably. They observe, that some trees are only proper for thickets; others, only fit to be employed singly; and others, equally adapted to both these situations, not excepting that certain cedar, which is alive and thriving in a horizontal direction, they hold improper for thickets; because they indent into each other; and likewise cut disagreeably upon the plants which back them. They never mix these horizontal-branchee trees with the cypress, the oriental arbor-vitae, the cedrus, or the upright ones; nor with the arbor, the weeping willow, or the hawthorn, or any of a pendent nature; observing, that the intersection of their branches forms a very picturesque kind of network; neither do they employ together the catalpa and the acacia, the yew and the willow, the plane and the sumach, nor any of such heterogeneous sorts; but, on the contrary, they are admirers of the plane, the laburnum, the aspen, the birch, the sycamore, the maple, and plane, the chestnut, the walnut, the arborie, the lime, and all those whose luxuriant foliage helps their branches; and growing in globular masses, assemble well together; forming, by the harmonious combination of their tints, one grand group of rich verdure.

6149. In their smaller plantations, they employ trees of a smaller growth, but of the same concordant sorts; bordering them with Persian lilacs, guilder-roses, syringas, coronillas of various sorts, flowering raspberries, yellow jessamine, hypericum, the spira australis, thehesia, and roses, other flowering shrubs peculiar to China: and wherever the ground is bare, they cover it with white, blue, purple, and variegated periwinkle, the convolus minor, dwarf stocks, violets, primroses, and different kinds of creeping flowers; and with strawberries, tutsan, and ivy which climbs up and covers the stems of the trees.

6150. In their shrubbiries they follow, as much as possible, the same rules; observing farther, to plant in some places as few as possible, and in others more, as one time or another, any of those different methods the first is much the most brilliant; but its duration is short; and the appearance of the shrubbery is generally shabby, as soon as the bloom is off: they therefore seldom use it, but for scenes that are to last, in certain periods; preferring the last, or other occasions, as being of long duration, and less pleasing after the flowers are gone. (Dissert. on Oriental Gard.)

6151. British practice. Soon after Sir William Chambers's work appeared that of Wheatley, which contains some excellent remarks on the subject (Ob. on Gard. sect.xii. xiii. xiv.), and subsequently Uvedale Price's excellent Essays on the Picturesque, vol. i. In 1804 we endeavored to enforce the principle, not only in planting trees, but in arranging herbaceous plants, and the plants in botanic hot-houses. (Ob. on Planting and Landscape Gard. 8vo.) All these efforts were at first treated as visionary by Marshal, Nicol, and other planters and gardeners. But Nicol, in the last editions of his works, allows there may be some merit in grouping; and Sung, his editor, highly approves of following nature in the arrangement of trees. (Planter's Kalend.)

6152. Nicol says, "The proper disposition of shrubs, where many are to be planted, is a matter of considerable importance to the future welfare of the whole, and that whether they be mixed, or be grouped; that it is reckoned a conclusive proof that the shrubs are indiscriminately mixed, as is often done, or the evergreens be planted distinctly by themselves. The arrangement of shrubs is a matter, no doubt, very much of fancy. In some parts they may be mixed; in others grouped; but, in general, there ought to be plenty of evergreens planted, in order that the whole may be the more cheerful in winter. Generally speaking, the method of planting shrubs and the kind of trees, must depend upon the shrubbiries. Much more character and distinctness may be given, by judiciously grouping them, than by following the common methods of planting.

6153. In his commoner, rather horticultural editor, seems undecided in his observations on this subject. In one place he says, "In the distribution of plants over grounds dedicated to elegance, there are two rival systems, each of which has its practical followers and theoretical vindicators. One proposes the indiscriminate mixture of many different species; the other deliberately groups those only which have some marks of affinity. It is still a question, which order of planting is conducted by the hand of nature in self-sown vegetables; and which will confer on a garden the stronger claims to character and beauty?" He elsewhere observes, that "the different natures of herbaceous flowers, shrubs, and trees stand in the way of every attempt to govern their distribution or assembly by a common principle." In planting trees, however, he subjoins, "the principle of unity may be considered, without losing sight of the advantage of variety," etc. (Pr. Gard. 471.)
6154. Fruit-trees in shrubberies. "In shrubberies of considerable extent, fruit-trees may be interspersed at fifteen or twenty yards' distance, by which means a good deal of fruit may be obtained, and very much beauty added to the shrubbery. In spring the blossoms of apples, cherries, and pears are beautiful; in autumn their fruits and the foliage of cherries in particular, give a lustre and variety that highly brightens the appearance of other plants, especially of evergreens." (Villa Gard. Direct. 16.) This mode, Sir W. Chambers tells us, is practised by the Chinese when the patron is poor; that is, their shrubbery is composed of fruit-trees, and shrubs, and forms a sort of ornamental orchard. This we consider an advisable mode for an economical farm-residence; but the general introduction of fruit-trees, in even mingled shrubberies, unless of the species in their wild state, as crabs, wildings of pears, cherries, quinces, raspberries, &c. we consider as likely to destroy the character of the scene. It must be recollected too, that grafted trees, especially the apple and cherry, seldom grow so freely and produce such vigorous and natural-like heads as plants raised from seed; they are, therefore, soon overtopped by the others, or where they are placed among trees that do not grow higher than themselves, they seldom fail of producing deformed stunted heads.

6155. Forsyth, Abercrombie, and others, recommend their introduction, as it appears to us, without due regard to any other object than the fruit they will produce, and the fugacious beauty of their blossoms; but their unaccommodating form, and their influence as to character in ornamental plantations, we consider as sufficient arguments against the practice in general cases.

6156. Decorations in shrubberies. Those of the shrubbery should in general be of a more useful and imposing character than such as are adopted in the flower-garden. The green-house and aviary are sometimes introduced, but not, as we think, with propriety, owing to the unsuitableness of the scene for the requisite culture and attention. Open and covered seats are necessary, or, at least, useful decorations, and may occur here and there in the course of the walk, in various styles of decoration, from the rough bench to the rustic hut (fig. 561.) and Grecian temple. (fig. 562.) Great care, however, must be taken not to crowd these nor any other species of decorations. Buildings being more conspicuous than either statues, urns, or incriptions, require to be introduced more sparingly, and in the garden or ornamented scenery they should seldom obtrude themselves by their magnitude or glaring color; and rarely be erected but for some obvious purpose of utility.

6157. Covered seats and shelters are introduced of many forms, and under a great variety of names, such as root-houses, heath-houses, moss-houses, huts, shelters, (fig. 563.) bowers, caverns, caves, grottoes, temples, mosques, &c. besides plain covered seats either of wood or stone. The imitation of temples or mosques, as they must be on a small scale, is generally quite ridiculous. The propriety of introducing the others depends entirely upon the character of the scene. Light bowers formed of lattice-work, and covered with climbers, are in general most suitable to parterres; plain covered seats suit the general walks of the shrubbery. Most of the others may be introduced in romantic, singular, wild, or melancholy places.
6158. Statues, whether of classical or geographical interest (figs. 564. and 565.), urns, inscriptions, busts, monuments, &c. are materials which should be introduced with caution. None of the others require so much taste and judgment to manage them with propriety. The introduction of statues, except among works of the most artificial kind, such as fine architecture, is seldom or never allowable; for when they obtrude themselves among natural beauties, they always disturb the train of ideas which ought to be excited in the mind, and generally counteract the character of the scenery. In the same way, busts, urns, monuments, &c. in flower-gardens, are most generally misplaced. The obvious intention of these appendages is to recall to mind the virtues, qualities, or actions of those for whom they were erected; now this requires time, seclusion, and undisturbed attention, which must either render all the flowers and other decorations of the ornamental garden of no effect; or, if they have effect, it can only be to interrupt the train of ideas excited by the other. As the garden, and the productions of nature, are what are intended to interest the spectator, it is plain that the others should not be introduced. This reasoning, while on the one hand it shows the absurdity of such a practice, on the other, directs that urns, monuments, &c. should only be placed in solitary unfrequented places, where the mind is naturally led to contemplate, and where the remembrance of the virtues of great men, or the worth of relations now no more, afford proper subjects for contemplation. But even in places apparently solitary, or secluded, these have been introduced in so affected or improper a manner, as to furnish reason for the greatest caution in future. (Tr. on Country Res.)

6159. A cottage, when the walk of a shrubbery is of great extent, may sometimes be advantageously introduced in a distant part of it, with an occupant, for the purpose of keeping one apartment in order as a place of repose. Such a cottage (fig. 566.) may be designed in any style, according to the taste of the owner, and may serve a variety of useful purposes. In the gardens laid out under the direction of the Queen of Geo. III. at Frogmore, and in the walks of what are called the slopes at Windsor, are some good examples of rustic seats, and ornamented shrubbery cottages.

6160. On the subject of planting both flower-gardens and shrubberies we may remark, with the author of the Floris's Manual, that it is considered in much too unimportant a light, both by gardeners and their employers. The business is almost every where performed at random, instead of being conducted with a specific object in view. To remedy this evil, gardeners should first make a correct plan of the border, parterre, or plot, of whatever kind it may be, that is to be planted; and then having determined the mode of arrangement most proper, and selected the names of plants to effect it, from the proper catalogues, the situation of every plant and its name should be determined on the plan. This done, all these points should be correctly transferred to the ground, and a pin or stake inserted at each, numbered in correspondence with a list of the sorts. The plants being procured, should then be distributed and planted according to these stakes and numbers; and the stakes should be allowed to remain for a year or two, to make certain as to the sort to be replaced there, in the case of death or accident. If ever this branch of gardening should attain a high degree of perfection in Britain, it will probably be deemed as necessary to call in a professor to direct the arrangement of flowers and shrubs in parterres and shrubberies, as it is now to require his aid in arranging the ground-plan.
Of the Hot-houses used in Ornamental Horticulture.

6161. The hot-houses of floriculture are the frame, glass case, green-house, orangery, conservatory, dry-stove, the bark or moist stove, in the flower-garden, or pleasure-ground; and the pit and hot-bed in the reserve-garden. In the construction of all of these the great object is, or ought to be, the admission of light and the power of applying artificial heat with the least labor and expense. In culinary forcing-houses, it is requisite to attend to the angle of the glass roof, so as to obtain most of the sun’s influence at the time the fruit within is to be ripened; but in the hot-houses of the flower-garden or pleasure-ground, the construction ought to be such as to admit as much light as possible in winter; for then in the stoves a heat is kept up by art, which is not to be found in any natural climate connected with so little light as is then afforded in our latitude. Hence, as a general principle it may be affirmed, that the roofs of all plant or botanic hot-houses should be steep rather than flat, and, perhaps, the angle of 45° may be fixed on as the fittest average. It was adopted by Miller, both in culinary and ornamental hot-houses, and is fitter for general purposes than any other.

6162. The frame used in ornamental horticulture is generally of the same form as those of the kitchen-garden. For alpine plants this form succeeds perfectly, but for frame-shrubs, the ends and front should be deeper than usual, and glazed half their depth, to admit the sun to the surface of the adjoining pots. Frames for the taller bulbous-rooted flowers, should either be glazed in front and at both ends, or if opaque in those parts, should be placed on a steep surface for the same general object. Frames of every description should have a gutter or spout in front, to carry off the rain-water which falls on the sashes.

6163. The glass case may be variously constructed from detached sashes; it is used to protect standard trees or shrubs, and sometimes to place against walls or espaliers. (see fig. 326.)

6164. The green-house may be designed in any form, and placed in almost any situation as far as respects aspect. Even a house looking due north, if glazed on three sides of the roof, will preserve plants in a healthy vigorous state. A detached green-house, even in the old style, may be rendered an agreeable object in a pleasure-ground, of which, as an example, we may refer to one (fig. 567.) erected by Todd, for E. Liebenrood, Esq. near Reading; but the curvilinear principle applied to this class of structures, admits of every combination of form, and without militating against the admission of light and air. Though we are decidedly of opinion, however, that as iron roofs on the curvilinear principle become known, the clumsy shed-like wooden or mixed roofs now in use will be erected only in nursery and market-gardens; yet we are not to be understood as exclusively recommending our own plans, and we, therefore, describe that of Todd, whose book contains a number of examples, erected in different parts of the country, and in the best manner of the old style. "This house (fig. 567.) has a span roof, and the centre lights, which are balanced by weights, made in imitation of acorns, suspended from the ridge of the roof, are made to slide, to admit air from the roof. The front and ends are formed with folding casements, hung so as to be taken away at pleasure; and between each is a pilaster of treillage-work. A cast-iron column at each extremity of the upper part of the roof, is placed for the purpose of keeping it from spreading, as such roofs generally do, unless held together by a transverse tie, which has a less pleasant appearance than a column. A
single fire heats this house; the flue goes under the floor round the front and ends, rises and continues above the floor along the back wall, and terminates in a chimney in the centre. Over the stock-hole is placed a cistern, which is supplied from the roof, and occasionally from a pump adjoining, with water, which is conveyed into the green-house by a lead pipe." (Plans for Green-houses, &c. p. 11.)

6165. The most suitable description of green-house or conservatory for the flower-garden is that with span roof (fig. 568.), because such a house has no visible "hinder parts," back sheds, stock-holes, or other points of ugliness, with which it is difficult to avoid associating all the shed, or lean-to forms of glazed buildings with back walls. Several elegant houses of this description have been erected by Messrs. Bailey. An example occurs in the Regent's Park, at the villa of W. H. Cooper, Esq.; another at Walthamstowe, in the grounds of P. Kendal, Esq.; and several more are mentioned in the table already given (1587.), or are in course of erection.

6166. In the interior of the green-house the principal object demanding attention is the stage, or platform for the plants. In a double-roofed house, surrounded by a path, the stage generally consists of shelves, rising from the path to the middle of the house (fig. 567. a and b); but in a house with a single roof (fig. 569.) it generally rises from the front path to the back, and in both cases the slope of the stage is generally the same or somewhat less than the slope of the roof. In the green-houses destined for very large or tall-growing plants, as camellias, and many of the New Holland plants, no stage is requisite; and in such as are destined for small plants, as heaths and geraniums, the first stage of the stage, when there is a path between it and the front glass, should be raised at least two feet and a half high, and it may then be continued parallel to the roof. The object of this arrangement is to bring the plants near the glass, so as they may obtain the benefit of the light in a state as little decomposed as possible. Flues in green-houses are frequently carried above ground, which is inelegant and too much in the style of the common forcing-house. They may in almost every case be conducted under the paths or stage, and by keeping them detached so as air may circulate round them, as much heat will be given out as by the common mode. In general one fire will be sufficient to warm from 4000 to 5000 cubic feet of air, of the temperature requisite for green-house plants. (see 1662.) In some cases trellis-rods are placed at regular distances under the roofs of green-houses, for the purpose of training vines; but this practice is incompatible with a high degree of culture and beauty in the green-house plants, on account of the light it excludes; besides, it interferes with character. If any creepers or climbers are to be trained under the roofs, they should be of the ornamental kind; but it is generally best to train them to upright rods at the back part of the house, or rods forming intersecting arches over the back paths, or against the back wall; for by either of these modes they exclude less light, better display their foliage and flowers, and less recall the idea of the forcing-house.

6167. Abercrombie and Nicol give descriptions of green-houses, such as they approve; the former is rather indefinite in his remarks; but the latter has given the best instructions that have yet appeared, as far as respects the old forms and mode of treating and ventilating.

6168. According to Abercrombie, "The green-house may be made a very ornamental object as a structure. The front of the building should stand directly to the south, and the ends have an open aspect to the east and west. The extent of the green-house may vary, according to the largeness of the collection to be cultivated: when most contracted it should considerably exceed the breadth and height, in order to have handsome proportions. As to the breadth, were it more than twenty feet, those plants most remote from the windows would be troublesome to manage, as they must stand on very high stages to be reached by the sun; between twelve and twenty feet will be found on most commodious latitude. The front, including a lower parapet wall and a row of windows, or upright glasses, may be eight or ten feet high, measured from the foundation, and at least three feet high above the level of the ground, and in damp situations two feet. The back is the only part at which an entire wall should be carried up to the roof; the precise height of this wall depends upon that of the glass front and the breadth of the house; the proportions of these three must be so accommodated as to give the proper slope to the roof." (Pract. Gard.)

6169. According to Nicol, "In the construction of green-houses, fancy may be indulged, and a greater scope may be allowed to taste, than in the construction of forcing-houses. These are generally confined to one object, and they affect the observer in passages by conformity of plants in person to their construction more necessary than in that of the green-house, where a variety of plants of different habits are to be cultivated. Nevertheless, in order that these plants may generally thrive, there are certain rules to be observed, and errors to be guarded against, which I shall briefly point out. Green-houses with upright fronts, and perpendicular columns, separate them into sections, whether the columns that separate them be of wood or of masonry, are the most objectionable; as the plants in such are always drawn up weak, and are distorted by continually stretching towards the light. Neither do they enjoy the genial effects of the sun, except in the winter months, when his rays, though feeble, strike horizontally on the window, and for a few hours in the middle of the day perhaps, shine on the low plants, and those placed most forward. If such houses be very wide, they are the most objectionable on that account; as, in that case, the plants placed near to the back of the stage are never visited by the rays of the sun, and enjoy but little light to what they may require. But such green-houses may be, and indeed have been, much improved, by taking off their leaden or slated roofs, and by substituting roofs consisting of wooden framing and glass, for the admission of sunshine and perpendicular light. But still they are so far defective, as that, by their great height, the plants are much more drawn than they ought to be, or would be, in a
lower and better-constructed house. Houses that are open on the front only, although they have sloping lights on the roof, are next to be objected to; as the plants in such are necessarily more drawn and dishevelled than if the ends were also glazed. If such be not placed among other buildings, so as that they can not be altered, they might be very much improved by pulling down the close ends, and by substituting glazed lights; which, if they be of a moderate height, would render them next best to such houses as are described below.

6170. A complete green-house, being quite detached from other buildings, should be glazed on all sides. It may be a circular, oval, hexagonal, octagonal; or with two straight sides, and circular ends, which I think the best form of any; the next best, an octagon, whose sides are not equal, but with two opposite longer sides, and six shorter sides; three and three opposite, forming, as one might say, an angular oval; the ends being angular, instead of round. In either of these last-mentioned forms, the stages and plants may, at least in my mind, be more tastefully arranged, than in any other. Granting either of these cases, the house should be about thirty-six or forty feet long, eighteen or twenty feet wide, and ten, or at most twelve feet high, above a given level line for its floor. The parapet all round to be a foot or fifteen inches high, and the upright glasses placed on it, four, or four and a half feet at most. For it is of importance, for the sake of the finer kinds of plants, and in order to have all kinds grow bushy, and flower while young and small (in which state they are certainly most attractive and pleasing), to keep the roof-glasses as low as possible; just allowing sufficient for the best person when walking in the alleys. The furnace and stock-hole may be placed at either end, or at either side, as may be most convenient; and they should be sunk under ground, and be concealed. The flue to be constructed, to run parallel to, and be separated from the parapet by a three-inch cavity; its surface being level with the top of the parapet; and being crib-trellised for heating, Botany Bay, and other rare plants. A walk thirty or thirty-six inches broad, to be conducted all round next the flue; within which to be placed the stages for the more common, and the taller plants; being raised in the middle, and falling to either side and end; corresponding with the glasses, though of course not so steep. A row of columns should be placed in the centre, in order to support the ridge of the roof; to which climbing plants might be trained in various forms, and might be hung in festoons from column to column at top, or otherwise, as may be dictated by fancy. The front of the stage all round should be raised about eighteen or twenty inches above the walk, in order to raise the height of the plants placed on it, sufficiently near to the glass; thus forming the walk into a deep alley; the person walking in it having a narrow border of the finer and smaller plants on the one hand, and a bank of the more common and larger kinds on the other; than which, when the plants are healthy and thriving, few scenes can be more pleasing. The aspect of such a house should be towards the south; that is to say, it should stretch from east to west, or as nearly so as circumstances will permit. It may have an entrance on the south side, or one at either end, as shall be most convenient and suitable to its connection with the walks of the shrubbery or parterre in which it is placed. If a green-house must necessarily be attached to a wall or other building, it might be constructed very much as above; with this difference, having one of the ends, as it were, cut off; in which case, it should be placed with its circular end south, or towards that point, and the sides pointing east and west. This I should consider as the second best-constructed green-house, and in which, excepting in the above-described house, the plants would enjoy the fullest share of sun and light. In either of these houses, and in plant hot-houses of every description, a sufficient number of the upright and sloping sashes should be made moveable, for the admission and regular circulation of air in the better seasons of the year; and ventilators should be placed at regular distances all round, for the purpose of airing and ventilating them in the winter months, or at times when it may not be safe to open the lights. Such a house as either of these, would form a very complete receptacle for a handsome and pretty extensive collection."

(Kat. and Villa Gard. Direct.)

6171. The orangery is the green-house of the last century, the object of which was to preserve large plants of exotic evergreens during winter, such as the orange tribe, myrtles, sweet bays, pomegranates, and a few others. Geraniums, heaths, fuchsias, and other delicate plants requiring much light, were then unknown. The orangery was generally placed near to or adjoining the house, and its elevation corresponded in architectural design with that of the mansion. From this last circumstance has arisen a prejudice highly unfavorable to the culture of ornamental exotics, namely, that every plant-habitation attached to a mansion should be an architectural object, and consist of windows between stone piers or columns, with a regular cornice and entablature. By this mode of design, these buildings are rendered so gloomy as never to present a vigorous vegetation, and vivid glowing colors within; and as they are thus unfit for the purpose for which they are intended, it does not appear to us, as we have already

observed at length (1590.), that they can possibly be in good taste. Perhaps the only way of reconciling the adoption of such apartments with good sense, is to consider them

570
as lounges or promenade scenes for recreation in unfavorable weather, or for use during fêtes, in either of which cases they may be decorated with a few scattered tubs of orange-trees, camellias, or other evergreen coriaceous-leaved plants from a proper greenhouse, and which will not be much injured by a temporary residence in such places, which, as Nicol has observed, "often look more like tombs or places of worship, than compartments for the reception of plants; and, we may add, that the more modern sort look like a combination of shop-fronts, of which that at Claremont is a notable example." Sometimes structures of this sort are erected to conceal some local deformity, of which, as an instance, we may refer to that (fig. 570.) erected by Todd, for J. Elliot, Esq., at Pimlico. "This building was constructed for the purpose of preventing the prospect of some offices from the dwelling-house. The architectural ornaments, and the roof, not being of glass, are points in the construction not generally to be recommended; but, as it was built for the purpose above mentioned, the objections were overruled. There are three circular stages to this house, which are made to take out at pleasure. The ceiling forms part of a circle, and the floor is paved with Yorkshire stone. It is fifty feet long, and thirteen feet six inches wide, and heated by one fire, the flue from which makes the circuit of the house under the floor." (Plans of Green-Houses &c. p. 10.)

6172. Of the orangery considered as a house for growing the orange tribe, as a dessert-fruit, we have already treated. (5930.)

6173. A recent and very considerable improvement in the construction of green-houses and orangeries consists in forming the shelves and stages of thin plates of stone, instead of boards; and very frequently the flag-grooves are hollowed out, so as to leave a raised margin of half an inch or more, for the purpose of retaining moisture, preventing dripping, and raising, when the air of the house is warm, a general steam or dew. This may be considered, on the whole, as a real improvement, a proof of which is the readiness with which it has been adopted by nurserymen and practical gardeners. A substitute consists in raising marginal slips of boards to wooden shelves, and covering the board with a thin layer of gravel or scoria.

6174. The conservatory is a term generally applied by gardeners to plant-houses, in which the plants are grown in a bed or border without the use of pots. They are sometimes placed in the pleasure-ground along with the other hot-houses; but more frequently attached to the mansion. The principles of their construction is in all respects the same as for the green-house, with the single difference of a pit or bed of earth being substituted for the stage, and a narrow border instead of surrounding flues. The power of admitting abundance of air, both by the sides and roof, is highly requisite both for the green-house and conservatory; but for the latter, it is desirable, in almost every case, that the roof, and even the glazed sides, should be removable in summer. When the construction of the conservatory does not admit of this, the plants in a few years become etiolated, and naked below, and are no longer objects of beauty; but when the whole superstructure, excepting the north side, is removed during summer, the influence of the rains, winds, dews, and the direct rays of the sun, produce a bushiness of form, closeness of foliage, and a vividness of color, not attainable by any other means. We are decidedly of opinion, therefore, that a conservatory of any of the common forms, unless it were devoted entirely to palms, ferns, scitaminea, or other similarly growing plants, should always be so constructed as to admit of taking off the sashes of the roof and the front; and if it were a detached structure in the flower-garden, we should prefer a plan that would admit of the removal of every thing excepting the flues and the plants. There is an old conservatory of this sort in the flower-garden at Nuneham Courtenay, planted with orange-trees; and when the roof is removed, the flues, border, and bed are covered with turf, so that the trees appear as if planted in the open garden. The trees have stood there for upwards of half a century, are vigorous, and bear annually abundance of fruit. On the other hand, there are two conservatories at Knowle, with roofs fixed, or partially opening, which have not been erected more than four years, and in which the plants are already etiolated, and the lower branches dying off. When a conservatory is glazed on all sides, it should, if possible, be placed south and north, in order that the plants on both sides of the pit should equally benefit from the sun; when placed against a wall, the glazed side may face any quarter except the north. But as the removal and replacing of the roof of such immense conservatories as are sometimes attached to man-
ORNAMENTAL HOT-HOUSES.

Book II.

sions (fig. 571.), is attended with considerable expense, risk of breakage, and what is of still more consequence, risk to the plants, if they happen to be uncovered too soon in spring, or left too long uncovered in autumn, we would recommend the polyprosopic roof (1610. and fig. 261.) as by far the most perfect description of a hot-house roof that has yet been devised. With such a roof, the plants within may, at any time, in a few minutes, be as completely exposed to air, rain, dew, and sun, if these exist without, as if the roof were removed; and again, in a few minutes, they may be completely shut up. The improver who shall erect an extensive conservatory of this kind (fig. 571. a), and apply to it the regulating apparatus of Kewley (fig. 217.), will find himself in possession of the most unique and complete plant-structure in the world.

6175. The conservatory in comparatively humble and economical residences (fig. 572.), may consist of a number of rectangular sashes, connected and supported by means of light iron rafters. In the beginning of summer, the sashes may be removed and applied to the ripening of peaches, vines, or figs against walls, or laid over excavations in the form of pits, containing melons, cucumbers, &c. The light iron frame-work may either be removed, or remain, and be disguised by annual creepers, or by vines of the narrow-leaved sorts. Sometimes a cistern is placed in the conservatory for growing aquatics, and containing a few gold-fish; but as there are very few exotic aquatics which will thrive in the temperature of the green-house, this is seldom requisite, unless as a decoration, and for the use of the water in culture, and the appearance of the fishes. The temperature of conservatories being the same as of green-houses, the same proportion may exist between the flues and volume of air to be heated.

6176. The dry-stove is chiefly devoted to the culture of succulents. In design it need not differ from the green-house, unless, perhaps, in the stage (fig. 573. a) being placed somewhat nearer to the roof. The name and character of this structure is derived from the higher degree of heat generally kept in it, and from the air being less moist than in the bark-stove, where more water is used, and consequently more vapor generated. The volume of air to be heated by one fire in the dry-stove, should not exceed two thirds of that to be heated in a green-house or conservatory, similarly constructed and situated.
6177. The bark or moist stove differs from the last only in having a pit (fig. 573. b) for bark or other fermenting matter instead of a stage. This pit may be from two and a half to four feet deep, according as bark or leaves are to be used, the latter material requiring the greatest depth. It is commonly surrounded by a thin brick wall, but, in elegant structures, planks of stone, or plates of slate or cast-iron, are to be preferred, as a higher finish, and occupying less space. The roof, when necessary, may be supported from the iron columns from the middle of the pit. (fig. 574. a) Shelves may be placed against the back wall (b), and occasionally a narrow-leaved creeper run up the roof (c). Such is the common interior arrangement of a botanic stove, as may be exemplified in that designed by Aiton, and erected by Todd, in the royal garden at Frogmore. (fig. 573.)

We may add, that houses of this description are generally placed east and west against walls, on account of the shelter thereby obtained during winter, when a high degree of heat is kept up within, while the cold is excessive without. There are exceptions, however, in the plant-stoves of the more recent public botanic gardens, especially those of Dublin and Liverpool, which are placed with their ends to the south, and in the immense palm-house erected by Messrs. Loddiges, which stands east and west, and is glazed on all sides. In private flower-gardens the hot-houses frequently consist of a range (fig. 575.) containing

a green-house (a) at one end, a dry-stove (b) at the other, and a stove (c) in the centre. By this disposition the stove is easier kept up to the required temperature, though it loses the full influence of the light at the ends. In general, a stove requires double the number of fires required to a green-house of the same size.

6178. There is a peculiarity in the construction of plant-stoves which deserves particularly to be noticed; namely, that fewer openings for the admission of air are requisite than in any other hot-house, excepting the pine-stove. One reason of this is, that the degree of heat which must at all times be kept up in the enclosed atmosphere, is so much greater than that of the open air, that the difference in the specific gravity of the two fluids, when permitted to mingle by opening two or three sashes, produces a more active circulation, and sooner approaches to an equilibrium of temperature: another is, that however numerous the openings in the hot-house roof may be, they could seldom be made use of without reducing the house to too low a temperature; and a third and last is, that the plants being mostly kept in pots, and many of them, as the palms, being of slow growth, they are not so apt to etiolate as those of the green-house and conservatory. Hence it is, that the roof of a botanic stove may generally be erected at less cost than that of a green-house or conservatory; but particularly where iron is employed, and the curvilinear principle adopted.

6179. Houses of magnificent forms, and almost as light within as in the open day, might thus be constructed for the growth of palms, scitaminees, bamboos, and other tropical trees to be planted in the ground, as in the conservatory. These might also be detached in the flower-garden (as figs. 10. and 20. in Sketches for Curvilinear Hot-houses), or they might form an appropriate appendage to a palace in the oriental style. (fig. 576.) Indeed, there is hardly any limit to the extent to which this sort of light roof might be carried; several acres, even a whole country residence, where the extent was moderate, might be covered in this way, by the use of hollow cast-iron columns as props, which might serve also as conduits for the water which fell on the roof. Internal showers might be produced in Loddiges' manner; or the roof might be of the polyprosopik kind, and opened at pleasure to admit the natural rain. Any required temperature might be kept up by the use of concealed tubes of steam, and regulated by the apparatus of Kewley. Ventilation also would be effected by the same machine. The plan of such a roof might either be flat ridges running north and south (fig. 577. a), or octagonal or hexagonal cones (b), with
a supporting column at each angle, raised to the height of a hundred or a hundred and fifty feet from the ground, to admit of the tallest oriental trees, and the undisturbed flight of appropriate birds among their branches. A variety of oriental birds, and monkeys, and other animals, might be introduced; and in ponds, a stream made to run by machinery, and also in salt lakes, fishes, polypi, corals, and other productions of fresh or sea water might be cultivated or kept. The great majority of readers will no doubt consider these ideas as sufficiently extravagant; but there is no limit to human improvement, and few things afford a greater proof of it than the comforts and luxuries man receives from the use of glass—a material, as Cuvier observes (Magazin Encyclopédique, 1816), manufactured from seemingly the most useless débris of our globe, and an insignificant plant (salicornia) found on sea-shores. In northern countries civilised man could not exist without glass: and if coal is not discovered in these countries, say in Russia, it may at some future period become a question whether, instead of separate fires and stoves, double windows, &c. the most economical mode of procuring a proper temperature will not be by at once to cover whole towns with immense teguments of glass, and heating by steam or otherwise, the enclosed air common to all the inhabitants; or where glass was considered too expensive, whole villages might be covered with a roof of boards, and lighted night and day in the winter season by gas previously obtained from the fuel used to produce the steam; or the gas might be employed for heating, either by the generation of steam, or passing the air heated by the flame through metallic tubes.

6180. The aquarium. The greater number of exotic aquatics being stone plants, a cistern of water for their culture is commonly placed in the bark-stove, generally at one end of the pit, and so as to be as near the light as possible. The Duke of Marlborough, however, and some others, have erected houses on purpose for this beautiful class of plants, substituting a large cistern for the bark-pit. The aquarium, at White Knights, (fig. 578) built by Todd, "is constructed with a span roof of glass; the sides and ends are also of glass, as low down as the top of the flue. A cistern occupies the interior of the house, having a walk round it; it is lined with lead, and filled with a mixture of mud and water, proper for the reception and growth of such plants as require aqueous nourishment. A flue goes round, directly under the bottom of the cistern, for the purpose of keeping the water of a certain temperature. Another flue goes round the house above ground, and terminates in a chimney at the north-west corner. The bottom of the cistern, to receive the lead, is formed with slates, supported by transverse bars of cast-iron; a bottom of wood would have been more convenient for laying the lead upon, but as the flues are so near the bottom of the cistern, danger of fire was apprehended. The cistern is supplied with water by means of a pump placed at a convenient distance for that purpose." (Plans for Green-Houses, &c. p. 11.) This aquarium suits very well for such aquatics as grow to some height above the water; but for those whose leaves float on its surface, as is the case with the most numerous and beautiful genus of this class (Nymphaea), it is too far from the light. A more perfect plan would be, to have the cistern close under the front glass, and to have that glass rather flat, say at an angle of 15°; or two cisterns might be formed, one in the back part of the
PRACTICE but it like the imitate that 818 Then Eolians. water which recently pots, setting a sort of exotic the experimentally chamber. keeping pit Comte innovation the are for the be for the experimental that of winter. It is almost needless to add, that such flurs and fishes must be kept in such a quadrature of water, according as salt water or fresh was used. It may be thought by some that the machinery would be intricate and troublesome; but the power requisite is so very small, that it might easily be obtained by machinery on the principle of the wind-up jack, such as was used by Deacon in his ventilating machines. (Rem. on Hot-h. 85.) This kind of mechanism very often goes out of order, or requires a great deal of repairing, and would require no other attention than being wound up twice in twenty-four hours, and oiled occasionally. The same vault that contained it might serve for the furnace or boiler for heating the house.

6191. Wind. If instead of water in a circular cistern with its bottom so constructed, we suppose air, the same principle will regulate the motion of the air which in producing business and strength of stem are well known. The motion thus given would probably be extremely useful for young plants in close damp weather in winter, by preventing some sorts from freezing, and damping or removing the air from those others. For this purpose the machine might be considered as a kind of hospital, and the plants being in pots, might be set on either the large or small wheels, and kept there in motion for a longer or shorter period, according to circumstances.

G. M. Description of fire-heat for that produced by the fermentation of vegetable substances, is a recent innovation in the construction of plant-stoves. This has been done by heating the air of a vault or chamber above the pit, with smoke or steam, either by circulating these fluids in flues or tubes in the chamber, or filling the air by smoke, or smoke and steam. The latter has been conducted through the tan with a view to prolong its heat. The mode by heating an air-chamber below the pit was carried into execution by us so long ago as 1804, at Glenfuir (Tr. on Hot-h. p. 219.) and more recently upon a larger scale, for the purpose of growing pines, at Underley Park. (Tr. on Cours. Res. p. 385. pl. 11. fig. 3.) A plan very similar to that last has been adopted by Kent (Hort. Trans. ii. 389. and iii. 387. who at first plunged the pots in a bed of sawdust over the vault, thinking thereby to avoid the worms and insects that generate in decaying tan. He found, however, that when the sawdust became rotten, worms generated in it as freely as in any thing else, and has therefore given up the practice of plunging altogether, setting the thin layer of the sawdust sand placed upon the air-chamber. Thus situated, the plants are not apt to run through the bottoms, and over the tops of the pots, as is the case when they are plunged, which always occasions a serious check to the plants, whenever they are removed or required to be shifted. After above a year's trial, he says, "I think I can with certainty pronounce that plugging is not only unnecessary, but really worse than useless to plants, except where they have been injured and require to be drawn." A very obvious extension of this principle was the issue of bottom heat altogether, and the substitution of a platform of brick or pavement, or merely a bed of scoria or gravel for the bark-pit. This has been done extensively by Messrs. Lodidges, Kent, the Comte de Vande, and various others, with perfect success as far as respects large plants; but most stone-plants require to be originated and brought forward till they are one or two feet high in bottom heat. By keeping up a considerable atmospheric temperature, and by frequent waterings over the leaves, that some plants produced which at least must contain some heat, as experimentally proved, that where such heat is produced in plant-stoves the bark-pit is unnecessary for all general purposes. If we reflect for a moment," says Kent, "that in tropical countries, the stem, branches, and leaves are exposed to a greater degree of heat than from the sun only, it is equally extraordinary that a system of management so directly opposite to nature should have ever been adopted, or that it should have been so long practised. If a quantity of earth was to be raised from the root of any tropical shrub, growing in its native situation, there is no doubt its heat would be below the temperature of the air, therefore the roots of the plants in a stove ought not at any rate, to receive more warmth than their other parts." (Hort. Trans. iii. 288.)

6188. A propagation-house is a requisite appendage wherever a general collection of exotic plants is maintained; and the proper situation for it is in the reserve-garden. Such a house, like the houses used by nurserymen, does not require to be so light as fruiting or flowering houses; it may be little more than a large pit with the roof very flat (say from 120° to 150°), in order that all the plants may be near the glass; it should contain a bark-pit, raised to within eighteen inches of the glass in front, and 28 feet behind, a broad stone shelf in front, and two or more shelves in the back of the house, close under the roof, that is, over the path and flue. All shelves in hot-houses, it may be observed, whether of stone or timber, ought to have narrow ledgments along their edges, not less than an inch deep, by which the water which escapes through the bottoms of the pots is not only prevented from dripping, but retained to generate a salutary coolness and moisture. The fire-place should be formed at one end of the front (say the south-east corner), and the flue conducted along the front from about nine inches or a foot from the parapet, and so along the opposite end and back wall, till it terminates at the extremity of the latter, or the north-east corner. The door may be formed in the back part of the end in which the furnace is placed, and the path which surrounds the pit, should be made sufficiently low to admit of head-room. This plan may in some cases be doubled; that is, a similar arrangement of flues, &c. may be erected alongside the other, that is, the north side, with a movable board partition between them. The house fronting the north may be used for striking cuttings, or raising seedlings, and that fronting the south, for
nursing the plants so raised, till they are fit for removal to the principal green-houses and stoves. The partition is made to remove, in order to admit or exclude the sun's rays to the back-house in spring or autumn at pleasure.

6184. We have already stated that we consider steam the best vehicle for heating hot-houses of every kind, especially where there are several connected together. Thus where all the hot-houses of a residence are connected with the mansion, both the latter and the former, with drying rooms, hot water or vapor-baths, steaming apparatus for horse-food, poultry-houses (under particular circumstances), and various other appendages might be heated as well as the hot-houses. The spare steam might be employed as the first power to machinery, to raise water, to drive a mangle, &c. and a gas apparatus might be added, to admit of lighting up the whole. Repton has given a plan well adapted for this purpose. (fig. 580.) At one end of this design an aviary (1) is surrounded by a conservatory (2), and joined to a glass passage for flowers (3), which leads successively through an orangery (4), lobby (5), music-room (6), library (7), print and picture-room (8), breakfast-room (9), anti-room (10), dining-room (11), hall (12), and peach and green-house (13). The whole length of this range is three hundred feet. Even single stoves or green-houses may be more agreeably heated in this way than by smoke-flues, which are very generally attended by a bad smell, and vapors of carbonic acid and hydrogen. A very neat example of this kind (fig. 581.) is given by Hayward. (Hort. Trans. iv. 434.) "It is erected in a small conservatory, the boiler (a) contains about thirty gallons, and the pipes (a, n) are three inches in diameter, and so laid as to have thick planks resting on props (a, b, c) placed over them, to form the pathway round the house. Chambers are formed round the pipes, communicating with the external air, by surrounding them with larger pipes (c, c); and by means of small pipes (n, n) as much heated fresh air can be admitted into the house through different apertures (x, x) as can be wished." By laying the pipes with a declination of a few inches from their departure from the boiler till their return to it, the water of condensation is returned through a valve (A, D), which is a very considerable advantage; but this valve is much better placed in a close box outside the boiler, (an improvement made by Messrs. Bailey,) as admitting thereby of examining it with ease when out of repair. The air-cock (r), safety-valve (a), steam-gauge (n), and water-gage in Hayward's boiler, do not differ from the usual construction. The mode here described of admitting heated air, we would observe, must be used with very great caution, for we know experimentally, that no mode is more liable to overheat the atmosphere of the house when the fire or steam is brisk in the beginning of the night, and overcool it when the fire declines towards the morning. We have the same objection to Walker's Improved Construction of Hot-house Flues, as described (Hort. Trans. iv. 237.), by A. Seton, Esq. Here a cast-iron flue is enclosed in one of masonry, and the vacuity between them communicates with the open air at the stock-hole, and with the air of
the house at certain distances, by means of apertures in the top of the flue. The argument in favor of this arrangement, is that usually given for vacuities around furnaces connected with flues, as adopted by Stewart, Gould, and various others (Tr. on Hot-houses, p. 132.), viz. that "the current of external air, by commencing, when cold, at that part of the flue which is hottest, takes up the heat there where it is least wanted, and carries it to those parts at a distance from the furnace where it is most needed; and as the valves are to be chiefly opened in the latter situations, to permit its escape, it diffuses a nearly equal warmth over the whole house." Every thing in this plan evidently depends on the management of these valves; if they are left open during the night, the risk above stated is incurred; if during day, less heat being wanted, little advantage is obtained. In stoves, however, this plan, under judicious management, might be useful; but it must never be forgotten, that air can be rendered much hotter by a fire-flue than by a steam-pipe, and hence the danger to the plants. No one was ever more sanguine as to the advantages to be derived from furnace vacuities and air-flues than ourselves (see Tr. on Hot-houses); but after twenty years' experience, we must acknowledge that they are so liable to produce accidents, either by admitting smoke or burning up the plants (as the phrase is), that we now seldom recommend their adoption.

6185. Various pits and hot-beds will be required in the reserve-department of the flower-garden, for forcing shrubs and flowers, raising annuals, &c.; the construction of which having nothing peculiar, need not be here detailed. (See 1591. et seq.)

6186. The idea of cold-houses seems to have been first suggested by Sir W. Chambers (Dissert. on Orn. Gard. p. 90.), and it may be worth while to submit some hints on their construction for such amateurs in this line of cultivation as may be curious in the subject. A number of cold-houses which grow in the lowest temperatures; and for botanists in warm climates, who may wish to cultivate not only mosses, but the more perfect plants of elevated regions or northern climates; as for example, of the British or Swedish alpines in Spain, or in the south of Italy. The simplest form of a cold-house may be a vault of rustic masonry open at one end, along the floor of which a rill of water may pass, and from every part of the ceiling water may drop on the floor or bed, and descend to the rill in the centre. This is an obvious imitation of the dripping caves sometimes found in tracts of country abounding with calcareous rocks, of which, for instance, we may cite the dripping rock at Knaresborough, and the dripping cave near Rousseau's walk at Lyons; in which last, on the 19th day of June 1819, we found the thermometer at 49° whilst in the open air, under the shade of an adjoining mulberry-tree, it stood at 72°. Various mosses and jennermannia were in luxuriant formation in the interior of the cave, and some sorts of ferns near its mouth. Another imitation of such caves might consist of an open grove of chinks or oaks, among the lower branches of which lead pipes pierced with small holes, in Lodgée's manner (1689), might be fixed horizontally at regular distances, and these being supplied, during the warmer months, with water from a proper reservoir, would furnish a continual shower, which, with the assistance of the small rills furnished by the collected rain thus produced, would lower the temperature of the atmosphere sufficiently for the growth of such mosses and ferns as do not require much light; and the margin of the grove might be devoted to plants of a more perfect kind, requiring a low temperature and moist atmosphere. But a more perfect plan would be to form a house like a large pit, with a double glass roof, fronting the north. Over the outer roof should be a system of pierced pipes to keep it cool by a continual shower during sunset, and at the top of the back wall an arrangement whereby two or more separate and concentric coverings of canvas could be let down to exclude the sun during the day. Instead of fluxes of masonry, large tubes of lead or cast-iron should surround the house, to be kept cool by a continual stream of water passing through them. The pit might contain a large metallic cistern, filled with ice, to be renewed when thawed, &c. It would be advancing too far into the regions of speculation to particularise other minor details that would be required to render such a house complete; least of all to indicate whether it should either in Britain or the south of Europe, so as to produce a temperature of 32 degrees throughout the year. This would admit the cultivation, in pots and on pieces of rock, of lichens, mosses, and of all the more perfect plants which grow in the regions of perpetual snow. (See 1696.)

Chap. VI.

Of the General Culture and Management of the Flower-garden and Shrubbery.

6187. The cultivation of the flower-garden is simple compared with that of the kitchen-garden, both from its limited extent and the general sameness of its products; but to manage it to perfection requires a degree of nicety and constant attention beyond any other open-air department of gardening. As the stalks of flowering plants shoot up, they generally require thinning, and props for support; and the blossom, both of plants and shrubs, no sooner expands than it begins to wither, and must be cut off, unless, as in some of the ornamental shrubs, they are left for the sake of the beauty of their fruit. Weeding, watering, stirring the soil, cutting off stems which have done flowering, attending to grass and gravel, must go hand in hand with these operations.

6188. With respect to the general culture and manuring of the soil, it should be subjected, as far as practicable, to the same process of cultivation as the kitchen-garden. In the shrubbery this cannot be done, but it, and also the earth compartments of the flower-garden, should be turned over a spit in depth, and some vegetable mould, or very rotten cow-dung, added occasionally. Every two or three years the plants in the flower-garden should be taken up and reduced in size, and the beds or borders trenched, say one time at two spits deep, and another at three, and so on (see 2516), adding enriching compost or manure completely rotting, according to circumstances. If, instead of trenching, the old earth were entirely removed, and replaced by good loan from a dry upland pasture, the improvement would be still greater. Most herbaceous plants flower well in such soil, and for the more cultivated sorts, as border pinks, auriculas, &c. that require a rich soil, a portion of enriching matter could be added to each plant as border-paint, and a corresponding attention paid to such as required peat-earth, sand,
clay, or lime. In the shrubbery, a similar renewal of soil, and attention to the soils required by particular shrub-plants, is also required. The bank is a boundary, where the more delicate shrubs naturally rank, and where the herbaceous plants are chiefly arranged.

6192. With respect to the *times of planting, or sowing, and manner of cropping* the flower-garden and shrubbery. In the greater part of the surface being covered with shrubs or plants of perennial duration, very little cropping is required, a rotation may be adopted as a substitute for a rotation. The system now generally in use, and if croppers be replaced by the method of croping, is to divide the flower in April and May, and to say croppers are made to procure a protracted display. Biennials and perennials of the fibrous or rami¢c rooted kinds are transplanted from the reserve-department in September or in March; and such bulbous roots as are annually taken up, are generally replanted in November or February. When bulbs and other florists' flowers are ready for cropping, the cutting may be adopted as a substitute for a rotation. Thus the hyacinth, tulip, &c., may be continued by annuals, and those by the dianthus tribe, or dahlias, &c., but in borders and compartments planted in the mingled manner, as well as in shrubbery, a rotation is out of the question. Particulars of what is requisite for all kinds of plants, and to replace them by others of the same height and color. This may be done at all seasons of the year by the use of the transplanters; but the better mode is to have always an ample stock in the reserve-garden, of all the colors and heights, both of herbaceous plants and low shrubs, (of all the sorts is unnecessary,) in pots, and watered in the flower-house. If a defect appears, it can be remedied at once by turning the plant out of the pot into its situation in the border. Independently of disease or accident, fine showy species, answering in general color and height, may thus at pleasure be substituted for such as are less showy, or less to the taste of the master.

6190. Ornamental plants, whether shrubby or herbaceous, require to be pruned, trained, thinned, and dressed, according to the sort of beauty or effect expected from them. If they are grown chiefly on account of their blossoms, then they must be pruned on the same general principles as fruit-trees; but like bushes or shrubs generally, those which are to be well and crowded should widow where there is quire own ability on account of the beauty of their foliage; and still less where the tree or bush is planted for the sake of its natural shape. It is customary in some places to apply the hedge-shears to shrubs; but this is a barbarous practice, destructive of all these beauties, which ought to be exploded, unless in cases where, in reality it is a hedge, and as such is intended to be used under the aspect of artificial shapes. Ornamental plants require little pruning, but nevertheless something in this way may be occasionally required on the same general principles applied to trees. Where very large flowers are wanted, it is obviously advantageous to prevent the plant from expending its vigor in too great a number of them, or in mere shoots and leaves. Top-heavy trees, such as will require to be pruned, cut off by thinning out a part of their shoots. In some annuals, thinning is effected both by eradication and cutting, and in the more delicate sorts by pinching off the young shoot, when an inch or two high. Cuttings, or slips, should always be protected against heat or cold, or placed, or watered, or otherwise treated as the plant would be if it were a native. This requires the application of a constant supply of water, and this ought to be applied in such a manner that the surface of the soil is always kept wet; the soil, however, should not be watered in a manner that may injure the plant, such as by pouring water on the leaves, which is injurious to the delicate sorts, such as the fuchsias. Watering is an important part of the art of gardening; and if it is neglected to ensure that deep-green color and velvety textures which is, or ought to be, the characteristic of the British lawn, and which is indeed the pride of our island.

6192. Various tender sorts of plants and shrubs require protection by some one or other of the different uten- sils, structures, or contrivances, to prevent them from being injured during the winter, by coverings with snow, or by hand-glasses, or frames during winter; and from heat, by screens to produce shade during summer. The roots of many sorts require to be protected by ashes, rotten- ten, or litter, from frost, and the tops of others both shrubs and plants, to be guarded by fogs of fumes or smoke, in the extreme winters. In other cases, from rain, hail, and cutting winds. Great care must be taken to protect pots of plants from frost; by always keeping them plunged in earth or some non-conductor; or for the state in which a plant can be placed is so obnoxious to the baneful influence of con- gelation as that of being grown in a pot. Cutting plants require to be supported by poles or rods, as some sorts of honeysuckle, bignonia, aristolochia, &c.; by props, as pyramidal bell-flower, lobelia ful- gens, &c. or by branches or spray, as the nasturtium and pea tribe. Much of the beauty of the flower- garden depends on the manner in which these operations are performed. The prevalent error consists in overdoing the thing, in employing too stout and too long rods or props, and too many thick tuft branches, instead of such as are free-grown and open. Watering must be liberally applied to almost every part of the flower-garden during summer, and in the evening; it increases the progress, and enlarges the parts of all vegetables; gives a fresh appearance to the soil as well as the plants, disperses their odors, and keeps the surrounding atmosphere in good order, and tends to subdue various kinds of insects.

6193. Water, whether as an ornamental feature, or as an aquarium, should be kept clear both of weeds and of mud, and of aquatic weeds. Of aquatic weeds, the most troublesome in small aquaria are the corypha and byasi, which can only be removed by having the water changed, or by entrapping them with a rake or broom. The larvae of numerous insects are deposited in water in the neighborhood of ponds and lakes, as the elephant-hawk-moth (*Sphinx Eilenor, L.* (fig. 983.)), the dragon-fly (*Libellula, L.*), and many others. Of aquatic plants the kinds are the well known tipsy, of which some species (*T. oleracea* (fig. 583.)) glide over the water; others are held by many kinds, rather ornamental than otherwise, and others live entirely under it, and feed on the roots of plants. To de-
stroy, or at least greatly to keep under all aquatic insects, an effectual mode is to dry the pond for a day or two, but in the case of an aquarium it cannot be done; fish and frogs, their natural enemies, must therefore be encouraged, in order that they may attack them.

6194. Insects and vermin. These must be kept under in every part of the flower-garden and shrubbery, and we perfectly agree with the author of the Florist's Manual, that "the simple and laborious mode of picking away the animal, is the only one to which recourse can be had with permanent advantage. To give full efficacy to this method of rescuing plants from caterpillars, snails, &c. our attacks must be made upon them at particular seasons, which can only be done from such a knowledge of their history, as shall enable us to have warnings of them destroyed in the destruction of an individual of the species. Without, however, much research into their natural history we may, from common observation, understand that in the winged insect we may free our plants from an innumerable tribe of those which crawl, and which, in that reptile state, have the capacity of devouring the whole product of a garden. The two periods of change of form in the caterpillar species, seem to afford the most advantageous times to put an end to their existence. Thus, the ephemeral butterfly; if timely attended to, we may destroy the animal before it has acquired the power of disseminating its young progeny; and, in the intermediate and voracious state of caterpillar, every single one which is prevented attaining the winged form, preserves our flowers from a host of enemies. The green caterpillar is the most common foe to our flower-borders and in autumn attacks the branches of mimounette in such numbers as to afford an easy opportunity of their destruction. A more persevering enemy, and more difficult to exterminate from gardens, is the snail (Helix) and slug (Limax), which, forming their habitations under the soil, attack the roots of the flowers, and frequently destroy them before the gardener can be aware of the mischief, that too often becomes visible only when past reparation. Under a vigilant eye, however, plants will not twice suffer from the enemy not being ostensibly; as the symptoms of his vicinity may be marked by flowers perishing as they first emerge from their buds or bulbs, by leaves or petals being pierced in small holes, or having the appearance of being gnawed in growth, or from almost any failure in vigor which cannot be accounted for by external causes. In cold and dry weather the snail rarely appears, but after warm showers it may generally be found; early in the morning, and about the close of evening, are the usual times of their coming abroad, when they may be picked up in large quantities. They will, however, frequently molest a plant for a length of time without being visible, in which case, when there is reason to suspect their hidden attacks, the only method to enrap them is to place a common garden-pot over the infested root, and it will rarely occur that the enemy is not discovered, as snails fasten themselves to the sides or tops of boards, or mats, or cabbage-leaves, so placed, and thence are easily taken. In droughty seasons it will be of use to water the plant before it is covered, as the moisture of the earth will be an additional motive of attraction to draw the animal from his hiding-place. The smaller insects which infest rose-trees, and some herbaceous plants, can only be kept within moderate bounds by sweeping them from the branches, or by cutting off those wherein they are found in most profusion. In carrying off these diminutive enemies, birds are peculiarly serviceable. Insects generally attack those plants which are least vigorous; and the reason of the selection of such leaves is as being to decay may be, that in their declining
state they have usually a peculiar sweetness, probably perhaps owing to some saccharine juices which are preparing for the nutriment of the bulb or bud which is forming in their bosoms, for the nascent vegetal 6198. 6197. and 6195. 6194. 6193. 6192. 6191. activity of the root takes its rise. The cultivated bee is an insect which the gardener will of course take care not to destroy on account of its use; and it may be a question whether some species of the butterfly, moth, dragon-fly, &c. showing their presence in the garden, are not as beautiful as the four-blotched dragon-fly (Libellula quadrimaculata, L.) and the swallow-tailed butterfly (Papilio Machaon, L.) (fig. 584), which is reckoned the most superb of the British species. It is very local, but occurs near Bristol, Beverly, and in the New Forest. The larva feed on umbelliferous plants; the eggs are green, and are laid by a row of orange spots. It changes into the chrysalis state in July; and the perfect insect is found in August. There are two broods, the first appears in May, having been in the pupa state all the winter, and the other in August from the pupa of July. (Samuelite.)

6195. The cutting off flower-stalks, decaying flowers, leaves, &c. is to be done in most cases immediately after the flowers are faded; but there are exceptions where the leaves on the lower part of flower-stems may be requisite to strengthen the root, and where, as in the case of stips, some convallarias, eringoeces, &c. the parts of the flower are persisting, or the fruit or seed-pods are objects of beauty. The leaves of bulbous-rooted plants, and such others as are not prolific in foliage, should be carefully preserved till they have begun to decay; and, indeed, the base or root-leaves of no plant whatever should be cut off till this is the case, unless for some particular object. Every single flower, as soon as the petals begin to droop, should be pinched off, and especially every flower of the double kind. Every rose, when it begins to droop, should be clipped off nearly to the foot-stalk of the one which is about to succeed it; and when the last of the corymb has done flowering, then the common foot-stalk should be cut off back to the first strong leaf-bud: nothing is more unsightly in a flower-garden than rose-bushes where this has not been attended to. By employing women or apprentices to go over the whole pleasure-ground every morning during the four summer months, to attend to this business, it may be completely accomplished at very little expense. These and other points of management, we know, are considered needless niceties by many gardeners: but what is a flower-garden unless it is kept with the utmost nicety? Others will tell you, they have not time for such things; but where there is a real taste for neatness, time will be found. "No gentleman," Sir G. Mackenzie observes (Caled. Hort. Mem. iv. 19.). "ought to keep a gardener who does not understand that there is time enough for every thing, provided that time is not wasted, but properly regulated, and nothing too long delayed."

6196. Gathering flowers. Gather, if possible, only from the reserve-garden; for if the main borders and compartments are managed as they ought to be, much gathering will disfigure the plants. Always use the knife, and prefer such as are coming into flower, rather than such as are fully expanded. If possible, gather from crowded plants, or parts of plants, so that every gathering may operate at the same time, as a judicious pruning and thinning.

6197. The French rose gatherer presents a refinement in floricultural instruments highly characteristic of its origin. The general form of this little engine is that of a pistol; it has a handle and trigger like it, and a cutter in the manner of the wire pliers, or flower-gatherer (fig. 192), disguised as a barrel. A rod, answering to the ramrod, connects the pincers with the trigger, which, last, being pressed, opens the pincers, the latter holding the flower stem, opens the pincers to be gathered, and when the cutter operates, it may separate it at the precise point of the stalk deemed proper: things being thus adjusted, the trigger is drawn, and the deed is done.—Of course this instrument, like a number of other horticultural toys manufactured by the Parisians, is chiefly pour les dames.

6198. Gather them by inserting their ends in water, moist earth, or moss; and may be freshened, when withered, by sprinkling with water, and putting them in a close vessel, as under a bell-glass, hand-glass, flower-pot, or in a botanick box; if this will not do, sprinkle them with warm water, or with spirits of wine, or ether, and if this fails, insert their ends in water heated to 80° or 90°, and cover them with a glass.

6199. Grafting, budding, laying, &c. Operations of this sort require to be performed in the flower-garden and shrubbery, for enlarging, renovating, and otherwise improving shrubs and plants, or introducing new sorts; they are also required for the common purposes of propagation.

6200. Ordering seeds, bulbs, and plants. This business is much simpler in the flower than in the kitchen garden. For flower-seeds of most sorts, an order is simply given for a paper of a sort; mignonette, lupins, sweet peas, and may be ordered by the ounce; bulbous roots are generally ordered by number, either of mixtures or single sorts; and herbaceous plants, shrubs, &c. by name and number, or by the hundred or dozen in mixture. See the priced catalogue of any nurseryman.

6201. Neatness has been already a good deal insisted on in different parts of this work. We repeat, it is the dress and visage of gardening, and if necessary any-where, is more especially so in the flower-garden. A gardener who pretends to manage a flower-garden, even without the most vigilant attention to this point, at all times, is unworthy the charge. The first thing is to have a quick intelligent eye, so as instantly to perceive what is wanting, and the second is to be possessed of that principle of activity which immediately sets about supplying the want. Many gardeners have certain times for cleaning up, &c. and will go fifty times past a weed, stone, dead leaf, or some such article, which disfigures or injures a scene, without removing it, merely because the time for cleaning, &c. has not come. This is most abominably formal conduct, deserving the severest reprobation. A gardener ought to have his eye, his head, his heart, his hand, his knife, and apron, ready for action at all times, places, and seasons, when within the precincts of his charge. Let him drown this incessant care in his own way when he is without his scene of business, or in the hours of rest and refreshment; and let him not undertake it without adequate terms of remuneration. (See 2555. 2573.)
General Culture and Management of the Ornamental or Botanic Hot-houses.

6202. The general culture of floricultural hot-houses respects soil, choice of plants, planting in pots or beds, and arranging: after offering some remarks on these heads, we shall submit a few as to what is general in the management of the principal floricultural habitations, as the frame, greenhouse, and stove.

6203. Soil for beds or borders. The first operation of the gardener, after a conservatory or stove is finished, is to fill up the beds and borders with prepared earth. These being narrow, should seldom be less than three feet in depth, the bottom should generally be paved, and sloping to a drain or drains; and in cases of very dry soils, provision may be made for the roots extending themselves beyond the area of the house. In general, however, this is not desirable in stoves, as the roots might be chilled during severe frosts; but provision may be made for their extension under the paths, and every other part of the area of the house. When a variety of plants and trees are to be grown in such pits, no soil can be fixed on that will suit them all; but if the main body be a sandy loam, then, as each particular tree or plant is planted, a few cubic feet of this loam may be removed, and replaced by the soil best suited to the plant. The plant once established, be it what species it may, will not languish in a sandy loam, other circumstances being favorable.

6204. Choice of species and planting. The species of stove or greenhouse plants must depend on the sort of house, and a variety of circumstances which need not be entered into. For common purposes choose the showy-flowering, easily cultivated, and vigorous-growing genera, as geranium, camellia, fuchsia, jasminum, &c.; or evergreens, as the myrtle, proteaceam, &c. choosing from the tables in Chap. X. some plants of the principal colors to flower in every month. In planting broad central beds in a house, glass on all sides, the highest-growing kinds will be placed along the middle of the bed; but where there is a wall to the north, the highest kinds will be placed next it. With respect to arrangement, the limited space admits of very little; in general, it will produce the most showy and immediate effect to adopt the common mingled and shrubbery arrangement, which we have recommended (6193); but as the spectator lingers longer on the pavement of the conservatory or stove, than in the walk of the shrubbery, more prolonged interest will be produced by assembling such plants as belong to one genus, or natural order, by themselves; because this will be to unite what used to be considered the desideratum of taste—unity and variety; that is, a general harmony of character in the genus, tribe, or family, and yet, when examined in detail, a distinctive character belonging to each of the individual species which compose it. It is a very common practice to plant climbers in such beds and along narrow borders, close to the upright or front glass, to be trained under the roof. We most decidedly disapprove of this plan, in almost every case, as tending to defeat the whole object in erecting such houses. Very luxuriant climbers are thus produced, but it is at the expense of light, not one ray of which, if possible, should be prevented from falling on the plants in the body of the house. Climbers or creepers are highly ornamental, and may be planted in a variety of situations without injuring the other plants; for example, in the bed, and trained on rods, or up such props as may be necessary to support the roof; or, along the sides of a central walk in a house standing north and south, and trained over the walk on an arcade of rods; or, on a similar arcade over the back path of a single-roofed house, or on the back wall. It is a very common thing to see the cobra in greenhouses, and the fruit-bearing passion-flowers in stores, darkening the greater part of the roof, and the plants beneath growing or elongating fast enough, but weak and of an unhealthy languid green. It is only under the broad wooden rafters of old-fashioned hot-houses that any sort of creepers may be trained up the roof without materially injuring the plants below; and even in those cases the injury is considerable, unless they are kept within very narrow bounds. But if creepers are injurious in plant hot-houses, the introduction of vines under the rafters is still worse; for, besides darkening the plants below more than the others with their broader leaves, the incongruity of effect produced by the attempt to unite two opposite characters, is exceedingly disagreeable, and only to be tolerated in humble economical residences, where a greenhouse, perhaps, is the only glass structure.

6205. Arrangement of plants in pots. Where the house and the collection are small, or the plants few and large, the same observations will apply which we have advanced on the subject of planting the beds of conservatories or stoves; but when the houses and collections are extensive, then some plan of arrangement ought to be adopted. Here, as in shrubberies and flower-gardens, there are three modes, by mingling, by grouping, and by method. For general effect the first is the best, but for prolonged enjoyment and examination in detail, the two others are greatly preferable. An abstract view of the modes by mingling and grouping might be represented by lines (figs. 585, 586.), in which, by the mingled mode, the colors are as regularly arranged as checker-work, while, by the grouping mode (fig. 586.), they succeed each other in large irregular masses. By the first mode, there is only one plant of a color by itself; by the second, from half a dozen to three or four dozen, according to the size of the group and the plants.
6206. By either mode regard must be had to place the plants in gradation according to their size, from the front to the back, or from the lowest to the highest part of the stage, as well to give them every possible advantage as to light, as to present the greatest surface to the eye of the spectator. It is not desirable, however, to dress them so regularly, as that the general slope of verdure shall appear as if shorn or mown, for that both deprives the sides of the plants of a considerable portion of light and air, and the eye of variety of form, and light and shade; it will have a much better effect if somewhat irregular, and if here and there a distinguished individual appear above the rest as a standard.

6207. In arranging by method or botanically, either the Linnaean or Jussieuean classification may be adopted; the latter is unquestionably preferable, as exhibiting a more perfect relationship; and it may be considered as represented by the same lines as those delineating the mode of grouping by colors. (fig. 586.) Where the Linnaean method is adopted, the classes may either be grouped in irregular roundish masses; or, as the tallest trees and lowest herbs are often placed in the same class, it will answer better to dispose each class and its orders in irregular strips (fig. 587. m. d. t. tet. pentandra, &c.), from the lowest to the highest part of the stage, by which the dwarf plants of each class may be placed in front, and the taller farthest back.

6208. The botanic arrangements, it has been already observed, are only adapted for extensive collections and capacious hot-houses; on a smaller scale the mingled method, or that by grouping, will be most advantageously adopted. In the case of green-houses attached to living-rooms, and where there are reserve-houses to keep up a supply, only such plants as are in bloom should be introduced, and there the method by grouping the colors may be adopted with great effect. But whatever be the size of the house, or even the extent of a bed, or shelf, or any part of them, never let the plants be placed there in the present indiscriminate mode. In this, no regard is paid to any thing but height; or if any farther object is taken into consideration, it is to mix the kinds as much as possible, with a view, as is alleged, to produce variety. But the effect of this mixture, whether on a large or small scale, instead of variety, is sameness or monotony, which lessens interest, and finally produces indifference in the spectator. It is true, there is as great a degree of sameness in the mingled mode; but then it is the sameness of a formal and avowed regularity; whereas, the sameness resulting from the common mode of mixture, is the sameness of affectation,—a sameness resulting from an abortive attempt at something not attained. The one mode may be compared to the geometrical manner of laying out grounds, and the other to the mode by clumps and belts; both are alike artificial, but the former is avowedly so, and therefore has attained its end, while the latter affects to be an imitation of nature, and therefore disappoints. A safe rule for every gardener to adopt, whether in setting pots of plants on a shelf or a stage, however small either may be, and however limited the collection, is to keep each genus together, placing the tallest plants farthest from the eye. Sometimes this will form a thin, straggling group from the front of the shelf or stage to the back (fig. 588. pelargonium, geranium, and erodium), and at other times, a sub-orbicular group in the front (oxalis), middle (olea), or back parts (cassio). This is a very simple rule, easily recollected and applied, and every master and head gardener who approves of it, ought to insist on its being carried into execution in every case, whether in the open air or in hot-houses, where pots of plants are to be set down together; unless, indeed, it should, in the case of diseased plants, interfere with culture. The effect of this mode may be very well estimated by inspecting the hot-houses, or open air collections of pots.
in some of the nurseries, and more particularly in Messrs. Lodiges', where this arrangement, both in the extensive green-houses and beds of pots of alpines and other herbaceous plants, is adopted on account of its utility.

6209. The following directions respecting the particular plant-habitations of floriculture, are chiefly taken from Sweet’s *Botanical Cultivator* (of 1820), and Cushing’s *Exotic Gardener* (of 1814).

6210. Frame. Very little management is requisite for this department, as the plants kept in cold-frames are so hardy, that for seven or nine months of the year the sashes do not require to be put on. All that is requisite is to expose the plants to the air the whole of every day during winter when the weather is open, by drawing off the lights; to attend to watering them moderately, during winter in mild weather in the morning after sunrise, and in summer in the evening. Once a-year in spring each plant should be examined, and such changes made in the soil, size of the pot, head of the plant, roots, &c. as the experience of the gardener, the appearance of the plant, or the object desired by cultivating it may dictate. The routine culture of weeding, staking, picking off decayed flowers, leaves, &c. need not be insisted on; and the culture of particular species or even tribes cannot here be entered into. (See the *Catalogue of Frame Plants*, in Chap. VIII.)

6211. Green-house. The plants of this department, Sweet observes, only require protection from frost in winter. The more air they have given them when not frosty, the more healthy they will be. On a fine morning, the sooner air is admitted the better; but it is best to shut up pretty early in the afternoon, particularly if likely to be a cold night. No fire is required, except frost is expected in the night, or the house should be damp with continued wet weather; then a little fire is requisite to dry the house, as plants are more liable to be injured by damp than by cold. The plants should be looked over most days to see if any require water, which must only be given when quite dry, in the winter season: from nine to twelve o’clock in the morning is the best time for watering them; for, if watered in the afternoon, they are apt to be chilled at night, which makes their leaves look yellow and unhealthy. When the surface of the mould is green with moss, &c. the top should be taken off, and the surface moved with a flat stick, but not deep enough to disturb the roots; if a little fresh mould is wanting on any of them, it should be added. Always be careful to put the same kind of soil they are already grown in; for a different kind put on injures plants more than some cultivators are aware of.

6212. When the weather begins to get warm in spring, some air should be left all night to harden the plants before they are set out; a little must be left at first, and continue to increase it every night till they have full air, if the weather will allow of it. The time of setting them out in the open air depends entirely on the weather. Sometimes they may be put out with safety by the middle of May, in other seasons not till the latter end; but they had better stay in a little too long than be put out too soon. Calm cloudy weather is the best time for setting them out, when as sheltered a situation as possible should be chosen for them. The best time for shifting them in fresh pots is early in spring: some shift them before they are set out, and let them make fresh roots while in the green-house, which is a very good plan, particularly for young or tender plants. If any plants are too tall, and want cutting back, it should be done early in spring, as soon as they begin to grow; then they have time to recover themselves, and make good bushy plants by autumn.

6213. Cuttings require to be put in at various seasons, and in different situations. From Christmas to May may be considered the best time for cuttings in general; but some will require to be put in at various seasons throughout the year, according to the state of the shoots. The best time for watering green-house plants in summer is as late as possible in the afternoon, then they have all the night to refresh them. If watered in the morning of a warm day, they will dry again almost immediately. Plants should not remain out too long in autumn, as they are liable to get too much wet, and the worms get in the pots. The middle of September should be the latest, but give them full air as long as the weather will permit. (Bot. Cultivator, 121.)

6214. Stove. The management of stove plants, according to the same author, whose experience and success are exceeded by none in the cultivation of exotics, depends a great deal on the kind of house in which they are grown; but there is little difficulty in growing them well, if the house can be kept up to a proper heat, and a sufficient quantity of air can be given when required. Close glazing is to be preferred;
either the lights should be ledged, or the lamps stopped with putty, so that a sufficient quantity of air may be always given, and the house kept to a more regular heat. When the lamps of the glass are left open, a great deal of air is admitted, which is often injurious, particularly on a cold windy night. The thermometer should never be allowed to be below 60° of Fahrenheit’s scale; if it gets above 70° on a fine day, a little air may be given, which should be taken away early, and the house shut up warm; it then requires less fire to keep up the heat through the night. If the house is heated in the common way by flues, and the plants are plunged in tan, care must be taken not to give these too much bottom heat, as it will injure their roots, or too much water in winter, as it is apt to rot them. Particular care is necessary for watering in winter, not to wet the tan, as it makes the worms very troublesome; they often destroy young plants by throwing the mould out of the pots; but a better way is the now very generally adopted, viz. to do without plunging in tan. Some hot dung or tan may be still kept in the pit to throw up a little warmth, on which should be put a good thickness of sand or gravel for the pots to stand on, and the plants will thrive much better than when plunged in tan: it is also coming nearer to nature, which should be always studied in the cultivation of plants, both in soil and situation. In tropical countries it is the sun that heats the earth in which the plants grow, not the earth that heats the air; and the heat must be kept up in the stoves accordingly. If the houses are heated by steam, no tan is required. The plants may be set on stages, or any way that is most convenient. Some of them may be planted out in the house, where they will grow in greater perfection, and flower and ripen fruit better than when confined in pots.

6215. To have plants look well they should be always kept clean and free from insects: if infested with any species of aphid, the house should be smoked with tobacco, which instantly destroys them. The red spiders are likewise a great pest to conservatories, but one easily destroyed. One pound of sulphur vives, mixed up in a pail of quick-lime, and the flues brushed all over with it as a common whitewash, will destroy any quantity of them, and make the house look light and clean. The mealy bug is also troublesome if left to increase on the plants; but as soon as they appear they should be brushed off as well as the scaly insects; for, if left to increase, they will disfigure the plants, and be very difficult to get rid of. In fine weather the plants should be often sprinkled over with water from an engine, and the house shut up warm afterwards, which is a great means of keeping them clean and making them grow luxuriantly. Air should be given in the morning as early as possible, in fine weather, as it sweetens the house, and makes the plants healthy. It should also be taken away early in the afternoon, and the house shut up warm, that they may not be chilled by the night air.

6216. In potting plants care should be taken to drain the pots well with broken potsherds or rough bits of turf; for nothing injures them more than letting them get sodden with too much wet. The best time to shift them in fresh pots is the spring, but some will require to be shifted again in autumn, to have them thrive well. The free-growing kinds cannot be well overpotted if there be plenty of room for them in the houses; they will thrive and flower better for being in large pots. Others that are more tender should be kept in as small pots as possible, that they may not get sodden, and lose their roots. (Bot. Cultivator, I.)

6217. The reserve hot-houses of the ornamental garden may be divided into those for forcing hardy flowering plants and shrubs, and those for propagating exotics by seeds, cuttings, or otherwise.

6218. Herbaceous plants and flowering shrubs are generally forced in pots or low houses; and as soon as the flowering season is over, they are generally removed into the open garden season. The shrubs should be previously established in the pots, by being planted and plunged in the open reserve-garden a year beforehand: the autumn before forcing they should be thrown early into a state of rest, by covering them with canvas frames to exclude rain and sun, but so as to admit cold and air. The very hardy shrubs should be commenced in July; and the most tender ones, in November or early in December. Herbaceous plants of most sorts, especially of the fibrous-rooted kinds, may be taken up with balls, and planted in pots early in the autumn preceding the winter in which they are to be forced. Fusiform-rooted sorts earlier, as they do not rise so easily with balls; and the bulbous sorts, the bulbs being out of ground, may be planted in the end of autumn, plunged in the open ground, and covered with rotten tan or ashes, and taken up as wanted. It is of some consequence to remark, that the flowers should be pinched off both the shrubs and herbaceous plants, the summer preceding the forcing season, in order to communicate additional strength, and aid in throwing them more early into a state of rest. The bottom heat may either be from tan or dung, or a vault heated by flues or steam; but the former we consider as most to be depended on. The temperature of the air of the house may at first setting in the plants be kept at 30° or 35°; and in a fortnight, raised 10 degrees higher. After that, it may be kept up to 60° or higher, admitting air during sunshine. The temperature of the pit should be kept as high as that of the air. Successional supplies should be kept for the first fortnight in a cooler house, or in the coolest part of the pit; or the temperature, on their admission, may be somewhat lowered. The other points of routine culture need not be entered into.

6219. The propagation-house requires to be kept at a much more moderate tempera-
ture both as to the atmosphere and the bottom heat than the forcing-pit or the principal store. It need seldom exceed 60° in winter, and 65° in summer. Abundance of air must be given at certain seasons when damp and mouldiness begin to appear; and shading and watering, so as to produce a moist atmosphere, must be attended to in the summer season.
Floricultural Catalogue. — Herbaceous Plants.

6220. A floricultural catalogue, as copious as that which we have given of culinary plants and fruits, would greatly exceed our limits. Plants grown for ornament are so numerous, that we cannot particularise separately the culture of each individual species; but, with the exception of some of the more choice sorts, as the florists’ flowers, &c., must collect them in groups, and detail a mode of culture applicable to the whole group. We shall first commence with herbaceous flowers, and these we shall arrange as florists’, or select flowers, border-flowers, and herbaceous plants for particular purposes.

Sect. I. Florists’, or Select Flowers.

6221. Florists’ flowers are so called as being “flowers” by way of eminence, and because the principal sorts of them for a long time almost exclusively engaged the attention of the flower-gardener. The Dutch, in this, as in most other departments of gardening, were the first to bring it into notice, and more particularly by the great excellence to which they attained in the culture of florists’ bulbs. In the culture of that tribe, they still excel; but the fibrous-rooted flowers, as the carnation, auricula, &c.; and the tuberous-rooted kinds, as the dahlia, paony, &c. are brought to a higher degree of perfection in Britain than anywhere else. Ornamental flowers, like culinary vegetables which have been long and highly cultivated, acquire a magnitude, succulence, and conformation of parts which render them widely different from what they are in their natural state. This takes place both in double flowers, that is, when the petals of the corolla are increased in number, or by the transformation of other parts of the flower into petals; and also in single flowers, or those in which the petals do not exceed the common number. A flower so changed by cultivation, can no more be compared to the blossom of the same species in its wild state, than a headed cabbage or a broccoli can be compared to the wild cabbage of our sea-shores. Hence have been formed, by the common consent of florists, what are called canons of criticism, by which to estimate the properties of new varieties of established sorts of florists’ flowers. To the hyacinth, tulip, auricula, and a few other sorts, particular canons are adapted; but the merits of a number of other select flowers, double and single, are only to be judged of by general rules, such as fulness of floral leaves, roundness of outline, brilliancy and distinctness of color, &c. Under each species we shall give the established criterion, or canon, as far as generally agreed on. We shall take the plants of this section in the order of bulbous, tuberous, ramose, and fibrous rooted flowers.

6222. The bulb of the hyacinth is tunicated, the leaves broad and green, from the centre of which arises a scape, with a spike of flowers, pointing in all directions, and by which it is known, at first sight, from Hyacinthus nonscriptus, L. (Scilla nonscripta, W.), in which the scape is drooping, and the flowers all turned to one side. It is a native of the Levant, and abundant about Aleppo and Bagdat, where it flowers in February; here it flowers in March and April. It was cultivated by Gerrard in 1596; but had, doubtless, long before been improved by the Dutch, who have added greatly to the strength and beauty of the plant, and produced almost innumerable varieties.

6223. Varieties. Gerrard mentions the single and double blue, the purple, and the white. Parkinson, in 1629, enumerates eight sorts. Miller says, the Haerlem gardeners distinguish near 3000 sorts, and generally publish catalogues of them from year to year. At present, the taste for this flower being considerably abated, the Dutch and English catalogues contain only a few hundred sorts. Mason’s catalogue for 1830, contains three hundred sorts with names. These names are quite arbitrary, being given by the grower after himself or some public character; and therefore they are here omitted. They are arranged as double blues, whites, reds, and yellows, and single sorts of the same colors; the blues and reds are the most numerous; the yellow, those of which there is least variety. Only single hyacinths were at first cultivated; but about the beginning of the last century attention was paid to double flowers by Peter Voserhelm, whose first double flower was named Mary, and is now lost; but his third flower, the king of Great Britain, which is now looked upon as the oldest double hyacinth, was greatly preferred to all the flowers known, and the price of it was then above 1000 florins, or 100l. sterling. Up to the middle of last
HYACINTH.

"The greatest attention was paid at Haarlem to raising new sorts of double flowers; and as much as 200l. has been known to be given for a root; but, since that period, the taste for this and other bulbous flowers has considerably declined, and at present there are few sorts for which more than 10l. are asked; these are either chief bulbs for the Myrtle Hyacinth, a bulb which is common mixtures are sold at from 2l. to 3l. a hundred. A variety degenerates, under bad treatment, in two or three years; but in Holland some have been preserved nearly a century.

Criterion of a fine double hyacinth. (Fig. 369. a) The stem should be strong, tall, and erect, supporting a mass of soft, white, or rosy, bloom. The roots should be covered with a little fine sand, which, however, had to be removed, and the flower, therefore, exposed to the full action of the sun. The colors should be clear and bright, whether plain, red, white, or blue, or variously intermixed and diversified in the eye. If the latter, it must be confessed, gives additional lustre and elegance to this beautiful flower. Strong bright colors are, in general, preferred to such as are pale.

6225. Propagation. By seed for new varieties; and by offset-bulbs for continuing approved sorts.

6226. By seed. "The seed should be saved from such sorts as have strong and straight stems, and a regular well formed pyramid of bells, not perfectly single, but rather semi-double. It should not be gathered till it has become perfectly black and ripe, at which time the pericarpium will appear yellow on the outside, and will begin to open. The stem, with which the seed is connected, is then to be cut off; and the seeds are then ready for sale. They may remain for a season unimpaired if kept in a cool place, but not the latter end of October, or beginning of March: it should then be sown about half an inch below the surface of the soil, in a deep box, filled with good sound garden-mould, mixed with sand, or the hyacinth compost recommended for the purpose, and watered with rain, or the juice of a roasted turnip. There is no need to be watered, or have any other attention paid to it than to keep it free from weeds and frost, till it has remained in this state two years; it must then, on the approach of winter, have an additional stratum of the compost placed upon it, about half an inch thick; and at the third year, in the month of July, the roots should be transplanted into the same box, with sand or other compost; the flower will flower the fourth year, one half of them will at the fifth, but by the sixth year, every healthy root will exhibit its bloom, and then the hopes and expectations of the cultivator will be realised or disappointed, for the first fruit of the root is soon exhausted, and will no longer flower at this period; if he can at last find one flower in five hundred deserving a name or place in a curious collection, he may rest perfectly content, and be assured that he has fared as well as could reasonably be expected, and better than many who have bestowed equal attention on the subject." (Maddock.)

6227. By offset. "One or two offsets, or offshoots, may be taken about the beginning of July, or six weeks after the bulbs have been separated from the parent bulbs. Plant them in an open part of the garden, in rows about two inches deep, upon a bed raised six or eight inches above the common level, consisting of a sandy soil, pulverised, eighteen inches deep; the surface of the bed should be made rather convex or rounding, so as to throw off heavy rains; no further attention is necessary, except to stir the surface of the bed occasionally, so that it may remain in a state of partial looseness. It must remain in this state two years; it must then, on the approach of winter, have an additional stratum of the compost placed upon it, about half an inch thick; and at the third year, in the month of July, the roots should be transplanted into the same box, or the same bed, with sand or other compost; the flower will flower the fourth year, one half of them will at the fifth, but by the sixth year, every healthy root will exhibit its bloom, and then the hopes and expectations of the cultivator will be realised or disappointed, for the first fruit of the root is soon exhausted, and will no longer flower at this period; if he can at last find one flower in five hundred deserving a name or place in a curious collection, he may rest perfectly content, and be assured that he has fared as well as could reasonably be expected, and better than many who have bestowed equal attention on the subject." (Maddock.)

6228. Choice of full-grown roots. "Such roots as have attained the age of four or five years, bloom stronger in this country than any other; they afterwards gradually decline, either by dividing into offsets, or diminishing in size and strength; but in Holland, owing to the peculiar circumstances of the climate, cultivators, &c. the same bulb has been known to produce blossoms twelve or thirteen times, nor is it ever known to die merely with age.

6229. Soil and site. "The bed on which they are to be planted should be situated in rather a dry and airy part of the garden; a southern aspect is to be preferred, sheltered on the north and east. When the situation is determined on, the dimensions of the bed should be marked out, and the soil entirely taken away to the depth of at least two feet; the earth in the bottom must then be dug up and pulverised, one sp or nine inches deeper, and the space above filled up with a compost consisting of one third coarse sand, four parts of fresh cow-dung, and one of straw. The earth is then divided into square pieces, and the compost exposed to the sun. This treatment is continued until the sun has baked the earth, and preserved it from very severe frost. The proper time to take them up is the same as for large roots. Offsets, if preserved in health, will bloom weakly the second year; but by the third year, they may be planted on the bed as already described.

6230. In the Dutch Florist of Nicholas Van Kampen and sons, florists at Haarlem (1760), and Newcastle-upon-Tyne, (1763), sandy earth is said to form the basis of the culture of the hyacinth. It ought to be of a bluish-grey or blackish-red color, not sharp, but rather handling smooth, a little greasy, and taking a pearl color when dry; the water passing through it being sweet and of a delicate taste. The best method of enriching sandy earth, according to their experience, is to make use of cow-dung, rotted leaves of trees, and tanners' bark; but the bark ought not to be taken fresh out of the pits, but laid up for some time and well constituted. The compost is either mixed with sand, or placed in the middle of the soil, and surrounded with the earth. It is possible that the result would be better, if the heap were laid in a high and open place exposed to the sun. Once a month it ought to be carefully turned, and the bottom thrown to the top, that all parts of it may partake of the benign influence of the sun. This compost must: this essential for the root, must be covered for twelve months, taking care not to sift the compost, because, in that case, it is apt to run into lumps, which would be of dangerous consequence." (Quot. by Nell, in Hort. Taur, 536.)

6231. In St. Simon's work, entitled Des Jacinthes (Amst. 1768, 4to.), in which the Dutch mode of cultivating the hyacinth is fully detailed, the compost used at Haarlem is said to be rotten cow-dung, rotten leaves, and fine sand. The leaves of elm, lime, and birch are preferred to those of oak, chestnut, walnut, hazel, plane, &c. which do not rot so quickly. The cow-dung is collected in winter from cattle, stall-fed upon dry food, without any mixture of straw or other litter. The leaves, when decayed and fit for use, are twice or thrice gathered, in the autumn; in the first gathering, they plant the root, and then the heap must be laid up for six months, and the heap is then dug up, and the leaves removed, and the cow-dung thrown up fresh, in which state it remains some weeks to settle before it is carried into the flower-beds. This compost retains its qualities about six or seven years; but the Dutch avoid setting hyacinths in it two years successively; in the alternate years they plant tulips, jonquils, narcissuses, crocuses, irises, &c. in the same beds, in which they remove the hyacinths after the first season, when the fresh manure might be injurious to them." (Herbert, in Hort. Trans. vol. iv. 165.)

6232. Planting. This should take place "from the middle of October to the middle of November; if it is done earlier the plants will appear above ground in the middle of winter; or if it is deferred later, the roots will be dry and it may be that the natural tendency to vegetate. On planting the roots, the surface of the bed should be covered with a little fresh sandy earth, about one inch thick, raked perfectly smooth.
even, and have the exact situation for every bulb marked upon it (fig. 590.), regularly mingling the colors of the tree, or shade white; the lows being classed with the latter. The width of the surface of the bed may be four feet, and six rows may be planted across it at six inches. Moreover, the two outside rows being each four inches from the sides of the bed; consequently the space between the central row and the bulb should be about inches and a quarter. On planting hyacinths, a little clean sand should be placed underneath, and, like saplings upon the roots, to prevent the earth adhering too closely to them; the whole are then to be covered with small boards, from three eights, from four inches deep, according to the size of the bulb; when this is completed, the bed will be about eight inches above the level of the walk on the south or front side, and about fourteen inches on the north; it will have a better effect, if it is supported on each side with a strong frame of thick boards or brick-work.

6233. The Dutch Florist directs, "After a place has been pitched on for planting the flowers, the natural earth must be dug out to the depth of three feet, and the bottom covered with a stratum of cow-dung half a foot thick. It will then be trowed down till it be very firm and compact like a hard crust, so as to prevent any communication with the sub-soil. Then the hole is to be filled up with compost, six inches above that of the garden. The compost should be laid into the designed bed about a month before the bulbs are planted; for if it be put in later, the earth might settle while the roots are in it, which would lay the proper season for putting in the bulbs to October and November. The outside row should be set at the depth of four or five inches; but early flowering varieties may be one inch deeper, which will bring them to flower at the same time with the others." (Quot. by Noll, in Hort. Tour. 551.)

In order to prevent its from very rainy or severe frost it very cold hooped over, and mats or canvass should be placed at hand ready to cover the bed on such emergencies; but it will not be necessary to defend it from moderate rains or slight frosts: for too frequent and long covering will deprive the roots of the use action and influence of the air, which ought to be avoided as much as possible: it would run the hazard of incurring a slight injury by the mission of covering or un occasions, than overdo it to the certain detriment of the plants. If frost is permitted to penetrate so far into the soil as to reach the bulbs, especially at the time that the plants begin to appear above ground, it will produce a singular effect, by causing some of them to shoot forth or discharge their stems and blossoms; but if the roots become entirely frozen through, they are in danger of being throrown. The earlier sorts will begin to open and show color about the beginning of April; it will be proper to screen such from the too powerful effects of the sun, which, if not prevented, would bleach and tarnish their colors, particular the blue. To prevent it, they are properly defended from it, their colors will be preserved, and they will, in some measure, be kept back, so as to be in full bloom with the later sorts, especially if the roots of the early sorts have been planted about an inch deeper than the rest: it is a very desirable object to have a uniform bloom. It will be necessary to support the stems as they advance in height; for this purpose wires, or wires, should be forced into the ground, immediately behind the bulbs, either in an erect position or leaning a little backwards, to which the stems are to be rather loosely tied with small pieces of green worsted, as soon as they begin to bend, or are in danger of breaking with the weight of the corolla or bells: this operation must be repeated as they advance in height, for it is impossible to do it at one time so as to answer the purpose. When the ground is bare, the shoots springing out in color, a covering, or awning, should be erected over it and the path in front: the awning should consist of a strong frame of wood, ten feet high in the centre, and seven feet at the sides, covered with Irish or Scotch flax, which will effectively keep out rain, and admit a great degree of light; it should come down close to the bed on the north side, in order to preserve it from cold winds, which are prejudicial to the bloom. The covering (fig. 591.) should be so constructed, by means of lines (a) and pulleys (b), as to be caned and expeditiously raised up, or lowered, as occasion requires, to afford the plants the full benefit of light and air, at all favorable opportunities, that is to say, when the air is mild, and light clouds intervene, so as to blunt the sun's ray. This sometimes, and, indeed, often happens to be the case from seven to nine o'clock in the morning, and from four to six in the evening, at which time the sun has also less power than in the middle of the day. A bed of hyacinths never requires to be watered at any period; the rains that happen after planting are generally more than sufficient both for the roots and the bloom; and after the bloom is over they are rather prejudicial than otherwise, except when very moderate. Although covering in the manner described presents and exhibits the bloom to the greatest advantage, yet this evidently has a tendency to injure and injure (fig. 591. b), and ought not, therefore, to be continued more than two or three weeks at most; but since as the general bloom declines, the beds should be immediately exposed to the open air, and the mats and hoops should be replaced, as before, to keep off heavy rains."
Van Kampen and son say, "We take up the roots as soon as the leaves begin to wither, that is, when their plants begin to turn yellow. We then break off the stems an inch above the bulbs, which we afterwards cover with earth, in which they are to lie till the gross moisture be dried up by the warmth of the sun. We then transplant it, bottom downwards, as they grow; and the heap is covered with an inch or two of soil. When the bulbs have lain in this heap for three weeks, they are to be taken out in fair weather, and laid on a board in the sun for an hour, after which, they are to be cleared of the earth and offsets about them, taking great care not to give the least bruise or wound." (Quot. by Newt. in Hort. Tour, 569.)

Herbert says, "The bulbs should be planted in a airy store-room, and not suffered to touch each other; a moveable stage of open lattice-work, furnished with drawers, may be used, and the utmost attention should be paid to the air; and when planted, Boucard, is said to have lost annually a number of his hyacinth-bulbs through dampness until he adopted the expedient of placing them in the store-room with the base of the bulb upwards. Drawers of lattice-work would effect the same object.

Diseases. "Hyacinths are subject to various diseases, arising from different causes; that distemper commonly known by the appellation of the ring-sickness, is of all others the most dangerous and most difficult to cure; in short, the only effectual remedy is to cut out the diseased part, till no brownness, yellowness, or other symptom of distemper remains. The sound part will survive the operation, if it consist of the inner layer of the bulb. If any heart is found, without any heart; but it will, in such case, only be able to produce offsets, and will never recover itself so as to flower again; as soon as the operation is performed, the wounded part should be exposed to the sun, till it becomes dry, to prevent mouldiness, and it will be best to replant it in some dry situation soon after." "The Dutch" Herbert observes, "are much troubled with this disease; the cause of which appears to be a fungus, the spawn of which is nurtured in the cow-dung. The only remedy is the removal of the distempered bulb, and the compost that was in contact with it.

Duration of bulbs. "The hyacinth delights in a sandy soil and saline atmosphere; of consequence it succeeds best on the sea-coast, or in situations very near to the sea. In more inland parts, it will generally be found necessary to procure an annual reinforcement of fresh imported bulbs, in order to make good or supply the deficiencies arising from the loss, or impaired health and strength of many of those that have been planted on any soil. Those who are well acquainted with botany, always will always allow one bulb in twelve to fail, notwithstanding no visible blight or decay is discernible at the time of planting; such generally have a corps de reserve, in narrow deep pots, which, at the commencement of the flowering, wherever only a small field of culture, or weak sickly plant makes its appearance, by which means the uniformity and regularity of the bed is preserved, without any visible defect or alteration." Herbert says, "My own experience enables me to say, that the nurseryman in the neighborhood of London may procure hyacinth-bulbs equal, if not superior, to those imported from Hol-land; though, perhaps, with greater ease from disease, owing to his not being able to procure the dung of cattle fed upon hard food, and free from straw." (Hort. Trans. vol. iv. p. 186.)

Forcing the hyacinth. Plant the roots in narrow deep pots, filled with sandy loam, in October; plunge them in and cover them with old bark-leaves or sand; they will soon throw down roots, and a part may then, say in November, be plunged in bottom heat, which will come into bloom by Christmas, and successional supplies can be taken from the store planted in October, and a bloom thus kept up till they flower in the open air. The best sorts to force are the single blues and reds.

Being hyacinths in water-glasses. Blue or dark-colored glasses are more favorable to the progress of the roots than light ones, light being injurious to all roots. The bulbs to be blown in the glasses should be planted in October, in earth in which they push their fibres more regularly, and taken up as washed, from the earth, and placed in the blowing-glass: the glasses may be kept in a warm room, or in a cold place, so that the water should be soft, and the bulb placed so as to rise from the water. When the flowers are perfect, and the bulb is found to be in full bloom, as the flower begins to wither, the bulb is to be lifted out of the glass in the same manner as above. As often as it becomes feter, it should be renewed.

The bulb of the tulip is solid, and sends up an upright stem from twelve to eighteen inches high, with glaucous leaves, and a large erect flower, the petals in its wild state having a black base. It is a native of the Levant. It is common in Syria, and is supposed by some to be the "lily of the field," referred to in Christ's address from the mount; though Sir J. E. Smith thinks the amaryllis lutea is there meant. In Persia, where the tulip is abundant, it is considered as the emblem of perfect lovers. "When a young man," says Chardin, "presents one to his mistress, he gives her to understand, by the general color of the flower, that his body is on fire with her beauty, and by the black base of it, that his heart is burned to a coal." According to Gesner, the tulip was brought to Europe in 1539. It was cultivated in England by James Garnet, in 1577, having been introduced, according to Hakluyt, from Vienna. Towards the middle of the 17th century, the tulip became the object of considerable trade in the Netherlands; it rose to its greatest height in 1634, and the three following years. According to Beckmann (History of Inventions, art. Tulip), for one root of a variety called the Vicerey, articles of the value of 2500 florins were agreed to be delivered. The Semper Augustus has been sold for 2000 florins; one person agreed to give 4600 florins (about 460l.), with a new carriage, two horses, and complete harness; and another agreed to give twelve acres of land for a single root. The trade was generally followed for a time, and having no foundation in real utility, like the Mississippi and South Sea schemes, it was a mere gambling business, and rightly named Tulipomania. John Barclay, the celebrated author of the romance of Argenis, is said to have had this mania to such an excess, that he placed two mastiffs as
sentinels in his garden. This was between 1600 and 1621, when he lived at Rome, in an ill airied and unhomelike habitation; in which, however, he chose rather to continue than abandon his favorite flowers. (Chalmers's Biog. Dict.) The taste for tulips in England was at its greatest height about the end of the 17th and beginning of the 18th century; about the year 1730 or 40, it had declined and given way to the taste for botany, and new plants from America and other foreign countries. The tulip, however, is still much cultivated both in Holland and England, near large towns, though in the latter country there are now very few good collections in the private gardens of the higher classes. Like the auricula and some other flowers, it is more the flower of the tradesman and operariable manufacturer than of the botanist or man of fortune.

624. Varieties. Parkinson, in 1629, enumerates 140 sorts: but "to tell of all the kinds," he says, "which are of the pride of delight, they are so many, and as I may say almost infinite, both both pass my ability, and, as I believe, the skill of any other." In Parkinson's time, "tulips were divided into praecoxs, or early bloomers, and serotinas, or late bloomers, with an intermediate division of duas nobilis, doubtful or doubtful. Of praecox, however, there were long, short, and middle sorts; and the Due Van Tholl is almost the only variety in repute among modern florists. The great variety in the catalogues is produced from the late bloomers, which have tall stems and much richer colors; of these the catalogue of Madock in 1794 contained the most. In Madock's catalogue, for 1794, there are six sorts for 30, or 600 single late sorts. The Dutch florists class their late-blowing tulips as under: a variety will last an unknown number of years.

Prime baguettes (baguette, Fr. a red or scarlet flower with long, fine, blue veins with wide, black broken with fine brown, and narrow, reddened or breaker.

Baguette Rigaux (supposed from Rigaux, a town in France), a large, red, single-flowered, in a vase, in the Royal Garden, which, for the size, is a flower, of great length and beauty. But they are produced only during the short period of the spring, and in those months which are characterized by the coolness and dryness of the weather, when the tulip is most circumstantly, and seasonally changing, the insertion here could be of no use. (See the Annual Catalogues of Bulbous Roots, published by the nurseriesmen and florists.) What are called breccers are procured from seed, and consist of one plain color on a white or yellow bottom. These being cultivated on a dry and rather poor soil become broken or variegated, and produce new varieties. The time that elapses before they break out from one to twenty years or more, and sometimes this change never takes place, so that whoever thinks of raising new varieties of tulips from seed must be possessed of an ample fund of patience and perseverance.

The early dwarf tulip, known among florists as the Van Tholl, is a distinct species, T. ocellataucris. Formerly there were several varieties of early dwarf kinds.

6245. Criterion of a fine variegated late tulip. "The stem should be strong, elastic, and erect, and about thirty inches above the surface of the bed. The flower should be large, and composed of six petals: the inner ones should be a little horizontal, and at first, and afterwards at the base, with a round bottom, rather widest at the top. The three exterior petals should be rather larger than the three inferior ones, and broader at their base: all the petals should have perfectly entire edges, free from notch or serrature; the top of each should be broad and well rounded; the ground-color of the flower, at the bottom of the blade, should be pure white or yellow, or a mixture of both. The principal ornament of a fine tulip should be regular, bold, and distinct, on the margin, and terminate in five broken points, elegantly feathered or pencilled. The centre of each leaf, or petal, should contain one or more bold blotches, or stripes, intermixed with small portions of the original or breeder color, abruptly broken into many irregular obtuse points. Some florists are of the opinion that the central stripes, or blotches, do not contribute to the beauty and elegance of the tulip, unless confined to a narrow stripe, exactly at the centre, and that they should be perfectly free from any remains of the original or breeder color. It is certain that such effects generally happen only when they have a regular narrow feathering at the edge; but the greatest connoisseurs in this flower unanimously agree, that it denotes superior merit, when the tulip abounds with rich coloring, distributed in a distinct and regular manner throughout the flower, except in the bottom of the cup, which, it cannot be disputed, should be a clear, bright white, free from any tinge, in order that the edge of the petals may be conspicuous.

6246. Propagation. By seed for new varieties, and by offsets for continuing approved sorts.

6247. By seed. Select such breeders as have tall strong stems, with large well-formed cups, clear in the bottom, and from these breeders, by means of offsets, derive the new sorts. Some of such sorts produces nothing but poor weak breeders of no value. "It should remain growing on the stem till the pericarion becomes of a brownish color, and begins to open; it is then sufficiently ripe, and should be cut off, with six or eight inches of the stem, and treated afterwards, in all respects, agreeable to the method of the Acroon, or the Lycanthy-seed. Some of the seedlings will bloom by the fourth or fifth, and most, if not all, by the seventh year.

6248. By offsets. These should be planted soon after they are separated from the parent bulb, in beds of fresh sandy loam, with a little rotten cow-dung placed from seven to twelve inches below the surface, in a double row. Two to five months, and two to five deep, according to the size of the offsets, raised six or eight inches above the alloys, formed rather convex on the surface, and may be provided with stones, or mats, to be used to guard them, as occasion may require, from heavy rains and severe frosts. The offsets should be treated the same, as the roots, imbedded in the earth at the root end, and are full, solid, and rather pointed at the other. Just before planting, strip off the brown skin so as to leave the root perfectly bare and white, performing the operation with great care, to avoid bruising or wounding the root, especially at the lower end, where the fibres are formed, which is, as the season of planting, extremely tender.

6250. Soil and situation. The situation for the best bed should be in an open airy part of the garden; when that is fixed upon, the ground should be marked out, agreeable to its intended dimensions, and the soil dug deep, then trodden hard, and raised six or eight inches above the alloys, formed rather convex on the surface, and may be provided with stones, or mats, to be used to guard them, as occasion may require, from heavy rains and severe frosts. The offsets should be treated the same, as the roots, imbedded in the earth at the root end, and are full, solid, and rather pointed at the other. Just before planting, strip off the brown skin so as to leave the root perfectly bare and white, performing the operation with great care, to avoid bruising or wounding the root, especially at the lower end, where the fibres are formed, which is, as the season of planting, extremely tender.
TULIP.

one eighth sea-sand, well incorporated, and laid in a bed, or stratum, for the plants, two feet deep." (77.

Carnation, Auricula, Tulip, &c.)

6251. Planting. The most proper time is from the end of October to the tenth of November.

On the day made choice of for planting, rake the surface of the bed smooth and even, still preserving its convexity, and mark the exact situation for every root upon it. The proper distance between each root is seven inches from centre to centre; and if the rows are seven inches asunder, the roots will form squares of similar diameter on all parts of the bed. A bed consisting of seven rows makes the noisiest appearance, when it is of sufficient length, with a path round it about two and a half or three feet wide; but where the number of roots is small five rows may suffice, and the path, in that case, may either extend quite round the bed, or only on one side, at pleasure. If, therefore, the bed consists of seven rows, it should consequently be fifty inches wide, which will allow a space of four inches between the outside rows and the sides of the bed; but if the bed contains only five rows, it will only require to be three feet wide, to give the roots similar distances. Having sprinkled a little clean sand where the roots are to be set, place them with great exactness and add some very sandy earth, so as to completely envelope each root in a little cone of it; then cover the whole very carefully with strong, sound, fresh loam, about four inches thick at the middle of the bed, gradually decreasing as it approaches the sides, where it should be about three inches thick; thus will the convexity of the surface be increased in a proper degree, and the roots will be covered with soil, to a depth proportionate to their size and strength; the largest and strongest having been placed in the centre rows, and the smaller and weaker on those of the outside. No tulip-root, whatever may be its size or strength, should be planted more than four inches deep from the upper side of the root; nor should any blooming root be planted less than two and a half or three inches deep, however small it may be. The soil made use of for covering the bulbs should be frequently turned over, and thoroughly exposed to the sun and air, some time before it is made use of, that it may be rendered perfectly sweet and free from the acid quality that most soils are subject to, when taken considerably below the surface. But if the bed is only to contain five rows, with a path in the front, and none behind, then it will be proper to plant the smallest and lowest growing roots in the front, next the path, and so gradually to increase in the size of the roots to the fifth or last row, which should contain the strongest and largest of all; when the roots are properly covered with soil, as before directed, the surface of the bed will slope one way, forming an inclined plane: it will be necessary to support its highest side at least with boards or brick-work, otherwise the earth would be liable to crumble down and leave the roots bare or too shallow.

6252. Future culture and management. When the operation of planting is concluded, the bed may be hooped over, and taken care of, in the manner directed for hyacinths, i. e. so as to preserve it from very heavy rains, and severe frosts; but either one or the other, in moderation, will be of more service than injury to it. By the end of February every plant in health will be visible above ground; some tall early sorts being forced to the height of a man, and the latter sorts just making their appearance; indeed, a very few remarkably late sorts may be a week longer before they appear, but not more: if, on examination, any diestumper or corker is discernible on the foliage, about this time, either above or an inch or two below the surface of the soil, it should be carefully cut out with a sharp knife, and the wound carefully filled up with a say a fine dressing of charcoal: it is the mark of a proper choice of for this operation. If the surface of the bed appears to be of too close and solid a contexture, it should be carefully stirred up, about two inches deep, which will admit the air more freely, and prove, in all respects, very beneficial. By the end of April, some of the earliest sorts, or those which probably require an earlier exposure to the sun, will have broken through the earth; in which case, it will cause the colors to run and intermix, in such a manner as to destroy the elegance and beauty of the flower; some sorts are more particularly liable to this effect than others, and will be spoiled in five minutes. When the greater part of the blossoms have begun to open, a frame, or awning, should be erected over the bed and paths, nearly similar to that for hyacinths (fig. 251): that is to say, so as to keep out rain, and admit as much light as possible; this must be thrown off, or rolled up, at every favorable opportunity, as directed for hyacinths, except that it should be done rather earlier in the morning, and later in the evening; because the sun has acquired a greater degree of strength and heat, which exposed to early coolness may be expelled, the colors of the flowers will be faint and weak, and the grandeur of effect will be lost, or considerably lessened. The cloth covering should come down on each side, within about three feet of the ground, to allow a free circulation of air, except in windy weather; from the effects of which, the flowers must be most carefully preserved, by a continuous scan of the covering quite down to the ground, on the windy side; a line of mats sewed together, and their upper edge nailed to the frame on that side, may answer the purpose, if the cloth is not of sufficient length. Tulips never require to be artificially watered, in the hottest and driest seasons, at any period from planting to taking up the roots; nevertheless, moderate showers may, after a very small degree of rain, be necessary, especially in the spring, in order to procure a strong bloom. When the awning is erected, the hoops should be carefully taken away, the sides and ends of the bed should be neatly boarded up, and the frame covered with a thick covering or two pieces of straw or with short pieces of straw, or with a cloth, which will preserve a pleasing regularity of appearance, without stiffness and formality. Tulips will bear to be covered a longer time in bloom than most other flowers, without sustaining any considerable injury: it may be continued three weeks with great safety. If any roots should perish, or fail to produce bloom, the deficiency may be made good by the transplanting, with the tube transplanter (fig. 93), from a reserve-bed, or the lower end of the stems of flowers, taken from the reserve-beds, may be immersed in phials, filled with water, and sunk into the bed, so as not to appear above ground; these will continue in bloom.
several days, without requiring to be changed, and will make a tolerable appearance. About a week or ten days after full bloom, when the petals of many begin to drop off, the swelling should be taken down, together with the upper part of the stem, and the roots and stalks large enough to fill the barrel. The leaves surround the base of the flower, and the part of the stem that remains in the vessel should be cut off, to throw off excess of rain, as the case may require: and as the leaves or petals of any fall, the seed-vessel of such should be immediately broken off close to the stem; for if suffered to remain on the plant, it will procrastinate the period of its maturity, and weaken the root considerably. The bed may remain in state about a fortnight longer, by which time the grass, or foliage, will become of a yellowish-brown, and two or three inches of the top of the stem will wither, dry up, and become purplish: this denotes the critical period to take up the roots, because if done earlier, they will be weak and spongy, and if deferred later, their juice will become gross; this will be manifest at the succeeding bloom, by too great a resemblance of colordic matter in the petals, and the flowers being what is generally termed fowl."

6253. Taking up the roots. Dig them up carefully, and place them under cover, in a dry, airy, shaded situation. Here they may remain untouched till August or September following. "Then it is proper to take off their loose skins, fibres, as well as other offscuts as may be, and then put the roots too bare, because the action of the air upon such would have a tendency to weaken and injure them, by drying up part of their juices; the last brown skin, which is so intimately connected with the root, should remain on it till the time of planting."

6254. Diseases. The tulip is hardy, and less liable to disease and injury from weather, than most sorts of flowers; it is sometimes attacked by grubs and wire-worms at the root early in spring, and then the best mode is to remove the plant and a portion of the soil, replacing the former from the reserve or offset-boxes.

6255. Forcing the tulips in pots or water-glasses. The early dwarf sorts are well adapted for this purpose, especially the Duc Van Thoël. They may be treated as in forcing the hyacinth.

6256. The ranunculus from a fasciculus of small tubers sends up several bipartite leaves, and an erect branched stem with a terminating flower variously colored. It is a native of the Levant, and was cultivated by Gerard in 1596. Though rather a tender plant, innumerable and highly beautiful double-flowered varieties have been raised from seed, chiefly by the English florists, from the middle to the latter end of last century.

6257. Varieties. Only double ranunculuses are held in esteem: of these, Parkinson, in 1629, enumerates eight; and Ray, in 1665, twenty sorts. Justice, in 1764, divides ranunculuses into Turkey and Persian; of the former he enumerates eighteen sorts, and of the latter a hundred. What he calls the Turkey ranunculus is only a variety or subspecies with a very dark flower, which Miller also considered as a species, and named it R. sanguineus. Maddock, in 1792, had upwards of eight hundred sorts. Mason's catalogue for 1820 contains about four hundred names. "There are more varieties of ranunculuses," Maddock observes, "than of any other flower;" but as their names are arbitrary, it would be of little use to enumerate them here. A variety will last from twenty to twenty-five years.

6258. Criterion of a fine double ranunculus. (fig. 593. a) "The stem should be strong, straight, and from eight to twelve inches high, supporting a large well formed blossom, or corolla, at least two inches in diameter, consisting of numerous petals, the largest at the outside, and gradually diminishing in size as they approach the centre of the flower, which should be well filled up with them. The blossom should be of a hemispherical form; its component petals should be imbricated in such a manner as neither to be too close and compact, nor too widely separated; but have rather more of a perpendicular than horizontal direction, to display their colors with better effect. The petals should be broad, and have perfectly entire well rounded edges: their colors should be dark, clear, rich, or brilliant, either consisting of one color throughout, or be otherwise variously diversified, on an ash, white, sulphur, or fire colored ground, or regularly striped, spotted, or mottled in an elegant manner."

6259. Propagation. By seed, for new varieties, and by offset-tubers, or dividing the tubers for continuing approved sorts.

6260. By seed. The seed of the ranunculus, Maddock observes, in no instance ever produces two flowers alike, or the same as the original. It should be saved from such semi-double flowers as have tall strong stems, a considerable number of large well formed petals, and rich good colors, when growing in the dark, but not to the exclusion of the lighter colored, when their properties answer the foregoing description. "The seed should remain on the plant till it has lost its verdure, and becomes brown and dry; it may then be cut off, and spread abroad upon paper in the seed-room, exposed to the sun, that every degree of humblity may be exhausted from it; in which state it should be put into a bag, and preserved in a warm dry place."
the flower, or other extraneous matter to be mixed with it, which would create a mouldiness when sown, of very destructive consequence; when the seed is scraped in a proper manner, drill or parplanit, of the centre of each cup, the kernel is the kernel. When the seed is thus prepared, it should be sown in a shallow frame, provided with sashes; the soil should have been previously taken out, three feet deep, and spread thin upon the ground, till it be about one inch deep, and then the seed should be carefully scattered to the required depth, and the soil, which will have contained, or kill many of the common earthworms. When the pit is filled up again with the frozen limbs of earth, it should remain till the whole mass has thawed, and subsided to its pristine bulk, or nearly so; its surface should then be made perfectly smooth and even, and the seed sown upon it, with much regularity, in such a manner that the soil would be placed in a firm and even stratum, and not be allowed to sink or to be covered. When the seed is sown, they can be placed very close together, for two or three days, till the seed begins to swell and soften; a little light sun should then be sited upon it, through a fine sieve, but not sufficient to cover it; this should be repeated, till the seed is several days old; if the soil disappears; it is advisable to remark in this place, that such seeds as have to be covered deeper than the thickness of a half-crown piece, will never vegetate, and must of course, inevitably perish.

622. It is necessary to keep the seed moderately moist, by gentle waterings with soft water, that has been left to stand for some time, the rose of the sun should be hemispherical, and perforated with a great number of very small holes, that will discharge fine streams of water, in a very distinct and regular manner. About the time that the plants begin to make their appearance, it is proper to stir the earth with the surface of a pin, or silver bodkin, just sufficiently to admit air, and give liberty to the young sprouts to be opened up to the earthy crumbling. To prevent breaking off the stipes, or raising and leaving any of the plants out of the earth, because one hour’s sun upon such would immediately destroy them. When the sun shines very hot, it is necessary to admit some shade under the glasses, and shade the frame with mats; but it should be close shut up with the glasses when the air is cold, and always at night.

623. After the plants are all up, and their two interior leaves appear, more air must be given, by having hurdles or lattice-work substituted for the glasses; waterings must be regularly continued, in the manner already described, when the leaves appear of dry vegetation it is necessary; but fine warm showers of rain are always preferable, when they happen in due time. This kind of management is to be continued till the roots are matured, and fit to take up, which is known by the foliage becoming perfectly brown and hard, or by the leaves being nearly concave.

624. The speciest and safest method of taking up these small roots is to pare off the earth, three inches deep, with a trowel or shovel, having previously carefully picked off the dried leaves, and any other extraneous matter that may be found upon it. The earth and roots, thus collected, are to be thrown into a frame. If the roots are in small clusters, they are to be worked in a large vessel or tub, nearly filled with water; the earthy part will, in consequence, be dissolved and washed away, and the roots will remain in the sieve, where, by a little management, they may be easily separated from the stones, &c. which are mixed with them. The upper rim of the sieve must, at all times, be held above the surface of the water, otherwise some of the smallest roots will be lost, as they are frequently found floating on the surface, till they have imbied a sufficient quantity of water to make them sink. The roots are to be dried and preserved, and are to be planted at the latter end of October, or at the commencement of November, in any other part, or such as have two or more claws, will blow strong the following summer. The Rev. W. Williamson sows half his seed in the autumn, and the other half in January, in the open air. He prefers the autumnal sowing, if the winter proves mild.

625. By offsets. Unlike the offsets of the hyacinth and tulip, those of the ranunculus generally attain a larger size than the mother plant, and therefore should be replaced by new tubers the same season in which they are removed. Smaller ones, which are unfit to bloom the following year, may be planted in a bed prepared as to be directed for the full-sized roots.

626. By dividing the tubers. In minutely examining the case of a ranunculus, several small tubers, which have shot as well arise, and the root may therefore be divided by a sharp knife into as many parts as there are protruberances; and thus the danger of losing any rare variety is much diminished. These sections will not bloom till the second year. (Hort. Trans. iv. 390.)

627. Choice of full-grown roots. Select such as are sound and full in every part, and have plump and prominent buds.

628. Soil and situation. According to Maddock, a fresh, strong, rich, loamy soil is preferable to all others; he recommends fresh dung, with a considerable portion of rotten horse or cow dung. The Rev. W. Williamson (Hort. Trans. iv. 375.) uses a stiff clayey loam with a fourth part of rotten dung. The situation should be open, but not exposed to violent winds or currents of air. "The bed should be dug eight or nine inches deep; and when the earth is taken from it, the peat, or rotten turf, should be set aside till wanted; it is a good thing to have a bed of peat, which is raised near the house, or placed in the garden, and as a manure, and also for the small roots of plants, that require a rich soil." 'The earth should be well broken, in order to the moisture being preserved in the soil, and to prevent the formation of chalk or lime. The surface of the earth should always be flat, and the amount of water, which is to be supplied, by the rains or from irrigation, should be sufficient to moisten the earth to a depth of six or seven inches. It is advisable for the roots to be placed in a bed, from which grass or turf, which is to be put on, is to be cut out and removed, so as to be as near as possible to the surface of the earth. The soil should be about four inches deep, and the plants should be placed near the surface, from three to four inches under, according to their size: when the trench has received its roots, it should be carefully filled up level with the same earth that was taken out, so as to cover the root exactly one inch and a half deep, which is the only true depth to procure a good bloom: it is pointed out by nature in a singular manner; for when these roots have been placed in a trench, and the root foliage turned down, the plant is weakened to such a degree that it seldom survives a repetition of it. Williamson plants in spring, but never after the tenth of February; and he frequently plants the roots in the same place for several years successively." (Hort. Trans. iv. 376.)

629. Planting. This may be done either before or after winter: if the soil and situation is remarkably cold and wet, it will be better to defer planting till the middle or end of January or beginning of February, as the weather may favor; but, in other situations, the latter end of October or beginning of November is to be preferred, as the roots will have more time to vegetate and form themselves, and will be the better prepared for the ensuing year. A few days before planting, those of the variety consisting of the variety called the scarlet-turbaned ranunculus, will produce a most brilliant effect; if planted at the same time as the tulip-bed, they will bloom together; they are harder than any other ranunculus, but may, in other respects, be treated in the same manner. The surface of the bed should be broken and well cultivated, and the earth should be placed in rows, one inch apart, in which the roots are to be planted, one on each side, and about four inches from each other. It is better to plant in shallow trenches, made nearly two inches deep, than to make holes for the reception of the roots: there should be a little clean coarse sand sprinkled into the trench, and the roots should be placed with their claws downwards; from these, to four or inches asunder, according to their size: when the trench has received its roots, it should be carefully filled up level with the same earth that was taken out, so as to cover the root exactly one inch and a half deep, which is the only true depth to procure a good bloom: it is pointed out by nature in a singular manner; for when these roots have been placed in a trench, and the root foliage turned down, the plant is weakened to such a degree that it seldom survives a repetition of it. Williamson plants in spring, but never after the tenth of February; and he frequently plants the roots in the same place for several years successively." (Hort. Trans. iv. 376.)

630. Future culture and management. Ranunculus-roots will remain several days in the ground after planting, before they begin to vegetate; during this period, they become very much swelled, by imbibing the moisture of the soil, and are, in this state, extremely susceptible of injury from frost; much more so than when vegetation has actually taken place. As soon as the bed is planted, a sufficient quantity of barley or oat straw should be placed near it, ready for a covering: in case of frost, it may perhaps be

Book II. RANUNCULUS. 853
necessary, during a very severe winter, to cover the bed in this manner ten or fifteen inches thick; but the straw should be taken off at all favorable times: for the effects of covering too much or too long are as destructive as the reverse, especially before the roots have begun to vegetate, because they are then more liable to become mouldy than at any other period, than which nothing can be more prejudicial. Early in the spring, when the plants make their appearance above ground, so as to render the rows easily discernible, the surface of the earth between each row should be trodden or beaten, so as to make it firm and compact; and if the soil is compressed with the fingers, quite close to the plants, it will keep out cold drying winds, and prove beneficial. It is advisable to make choice of a fine dry day, soon after rain, whilst the ground is still moist, to perform the above operation: when it is finished, a little long straw should be placed between each row, to preserve the surface of the soil cool and moist, till the foliage of the plants is sufficiently grown and expanded, to afford it shade without further assistance.

6271. Water. April showers, and frequent rains in May, are essentially necessary to the growth and vigour of the plants; if these fail, soft watering must be administered in sufficient quantity to keep the rows, by means of a common watering-pot, with a long tube or spout, held low, so as not to wash the earth into holes; for it is better to avoid watering the plants themselves, as it may chill them too much, and stagnate their juices. The consequences of omitting to water when necessary are these, viz. the plants will make little progress; the blossom-buds of the strongest will be small, and the weaker plants will not bloom at all; the grass, or foliage, will put on a sickly yellowish appearance, from which it will never recover during the season; and, lastly, the roots will, when taken up, be small and lean. But such kind of waterings, however necessary, are by no means so salutary to these, or any other flowers, as fine, watered earth; they can and should be equalled, nor are the plants naturally disposed to receive them when the atmosphere is dry, because their pores and fibres are contracted, and they, as it were, in the expectation of dry weather. Since it is evident that artificial waterings are, in all respects, superior to natural dews, in keeping the earth better therefrom to wait a day or two, in hopes of a change of weather, than to be too hasty in watering, although the plants may appear to suffer for the moment, by the omission; if such a change should fortunately take place, they will receive infinitely more benefit from it than when both themselves and the soil are already saturated, or replenished, with moisture.

6272. In dry weather in June and hot, the plants ought to be shaded at such times by means of lofty hoops and mats, or some better contrivance, that will admit light and air freely; a frame and covering, similar to that for hyacinths, would answer best, if expense and trouble were not to be considered: it will, however, be absolutely necessary to shade them, in some manner, during the period of bloom, otherwise they will continue but a very short time, especially the dark rich-colored sorts; for, in proportion as their colors approach to the black, is the injury they will receive from the rays of the sun, if permitted to shine upon them in full force; some of the very darkest cannot stand it one hour without some injury is indeed impossible. The deep colored sorts will bear the sun's rays much better, reflecting them in proportion as they approach to white; green is the only color that reflects and absorbs the rays of light in equal proportion, and is more predominant in the vegetable kingdom than any other. After the bloom is over, watering is no longer necessary, but shading, in the middle of hot days, is still very beneficial to the plants; it tends to strengthen their size and substance of their roots are thereby increased.

6273. Taking up the roots. By the end of June, or soon after, the greater part of the plants will appear brown and dry; vegetation has then ceased, and it is the exact time to take up the roots, because if they are suffered to remain in the ground till rainy weather ensues, they will begin to shoot afresh, and thereby sustain considerable injury. When the roots are taken up, their stems, &c. should be cut off close, and they should be placed in a shady airy room, or situation, to dry gradually; but before this is perfectly accomplished, it will be proper to clean and separate them, because, when quite dried, they become very hard and brittle, and the least attempt at breaking off their claves, some may be separated into many complete roots, although they are so closely connected, as, on a superficial observation, to have the appearance of only one large root. Nothing more remains to be done, till the return of the planting season, when it will be proper to sow the sorts separately in bags or boxes, for the sake of convenience, in a dry room, in which state it is possible to keep them out of ground for two or three years without perishing, although it evidently tends to weaken and injure them: there have been instances known of the ranunculus-roots surviving till the fifth or sixth year; they were, however, rendered extremely weak; or could any but very strong roots retain their vegetative properties so long a period. Williamson takes up the roots immediately after the color of the foliage begins to change.

6274. Forcing. The ranunculus may be forced, but loses much of its strength of stem and brilliancy of color.

6275. There are two species of anemone cultivated as florists' flowers, under the common name of anemone: the A. coronaria, L., or poppy-anemone (Bot. Mag. 841) (fig. 594. a), a native of the Levant, and introduced in 1596; and the A. hortensis, the star or broad-leaved anemone (b), a native of Italy, and introduced from Holland in 1597. The anemone has been cultivated from as early a period as the tulip, and many fine double varieties produced both by the Dutch and British. The single and semi-double flowers are nearly in as high estimation as the double ones.

6276. Varieties. These are numerous, but few of them are named. Parkinson, in 1629, enumerates thirty sorts of single narrow leaved anemones, and nearly as many double and single of the broad-leaved sort. Mason's catalogue for 1820 contains seventy-five sorts. A variety will last for twelve or fifteen years.
6277. Criterion of a fine double anemone. (fig. 595.) "The stem should be strong, elastic, and erect, not less than nine inches high. The blossom, or corolla, should be at least two inches and a half in diameter, consisting of an exterior row of large substantial well rounded petals, or guard-leaves, at first horizontally extended, and then turning a little upwards, so as to form a broad shallow cup, the interior part of which should contain a great number of long small petals, imbricating each other, and rather reverting from the centre of the blossom; there are a great number of small slender stamens, intermixed with these petals, but they are short, and not easily discernible. The color should be clear and distinct when diversified in the same flower, or brilliant and striking if it consists only of one color, as blue, crimson, or scarlet, &c., in which case the bottom of the broad exterior petals is generally white; but the beauty and contrast is considerably increased when both the exterior and interior petals are regularly marked with alternate blue and white, or pink and white, &c. stripes, which in the broad petals should not extend quite to the margin.

6278. Propagation. By seed for new varieties, and by dividing the root for continuing approved sorts.

6279. By seed. Select "single or semi-double flowers, that have strong, tall, and erect stems, large well formed cups, and petals of very brilliant colors. The seed must be gathered from time to time as it opens; for, being very downy and light, it will otherwise be blown away by the first breeze of wind, or fall down and be lost; it may be sown at the same time, and be treated in all respects like that of ranunculuses; the seedlings will, like those, blow strong the second year. It will be found very difficult to sow anemone-seed in a regular manner: it is united with, and enveloped in a downy substance, that upon being blown it is very difficult to separate; it is therefore necessary to make use of some sand or earth to separate it on sowing; nor will this be effected sufficiently without considerable labor in rubbing it for a long time amongst the earth, as it ought not to adhere together in lumps, which would not allow the young plants space enough to form their roots. There will be found but few double flowers amongst the seedlings, nor can it hardly ever be expected there should, if the seed be entirely saved from single ones; of course, the greater number of broad petals the flower of the seed-bearer possesses, so much greater is the probability of procuring large double flowers from the seed of it."

6280. By dividing the root. When the division is properly made, every piece will blow the first year, and is therefore to be treated in the same way as such are full-grown.

6281. Choice of full-grown roots. Select fresh plump roots of moderate size; large overgrown roots, which are hollow in the centre and often decayed, are to be avoided, as they never blow strong.

6282. First order of the bed. The soil for this purpose should be light, and well drained.

6283. Planting and future culture. The distance between the roots may be the same as for the ranunculus. Attend to place that side of the roots next the soil in which the decayed rudiments of small thread-like fibres will be observed, and cover about two inches deep. "Anemones are harder than ranunculuses, and, consequently, may be planted in the autumn with safety; the most advisable time is about the middle of October, by which means they will blow a week or two earlier than the tulips: if they are planted ten days or a fortnight after the tulips, they will all bloom together; but a few days later in the plant will scarcely be perceptible at the time of flowering: it is, however, possible that such plants, when planted in October, will blow stronger, and, when taken up, will be found of a larger size than those that are planted towards the end of November, especially if the winter proves mild; but if the winter sets in early, and proves severe, late-planted roots will not have time to vegetate before frosty weather takes place; in which case there will be great danger of their perishing, unless they are covered with straw, just sufficiently to keep frost from the roots, as they are then in a state of inactivity, but replete with moisture, which renders them more susceptible of injury from frost, and, at the same time, in much greater danger of mouldiness than after vegetation has commenced. The covering must therefore be taken off and put on, as often, and in such proportion, as the exigency or circumstance of the case requires." Water and protect from high winds and heavy rains, as directed for ranunculuses.

6284. Taking up the roots. "Anemones continue longer after bloom in a state of vegetation than ranunculuses, probably because of the greater degree of succulence; and even at the proper time to take them up, it will sometimes happen, that part of their foliage will not be entirely divested of greenness and moisture; this will often be the case when frequent showers of rain intervene, and are admitted between the times of blowing and the maturity of the roots: when it thus happens, much skill is required to ascertain the critical period to take up the roots; for if they are suffered to remain in the damp or wet ground a few days too long, they will shoot afresh, and be thereby materially weakened and injured; it is, indeed, better to take them up rather too early, than suffer them to re-vegetate in this manner; but the roots will not suffer as ill as if left for a longer time. The safest and most effectual method to preserve them from these disagreeable consequences, is to keep off all rains after the bloom is quite over, by means of mats on hoops; the roots will then regularly and gradually mature, and the foliage will, in like manner, become brown and dry, which will point out the true time to take up the roots; and this will usually be about the middle of November. The whole subsequent treatment of the roots, till the time of planting, is the same as for ranunculuses, with only the following caution, viz. that as the roots are exceedingly brittle, it is necessary to handle them very gently upon dressing or cleaning away their foliage; and all that adheres to them; however, should only small pieces break off, such should not be thrown away, as each will, in the course of a few years, become a blooming root, if it has an eye, without which it is of no value; but that seldom happens to be the case." (Maddock.) Anemones may be forced like the ranunculus; but, as it generally destroys the roots, the finest sorts should not be devoted to this purpose.

6285. The bulb of the crocus is round, solid, and compressed, with a netted skin, from the centre of which arise four or five grass-like leaves, and one or two flowers. Out of the centre of the tube of the flower arises a slender style, crowned by a broad flat stigma of a gold color. After the flower is past, the germ, which hitherto was seated on the bulb at the base of the tube, pushes out of the ground, and ripens its seeds; a singular economy in nature, and which occurs only in the colchicum, and a few other plants. All the known species of this genus may be considered as florists' flowers. Many botanists, indeed, reckon only two species, the C. vernus, or spring-blowing crocus; and the C. sativus, the saffron, or autumn crocus.

From the Crocus vernus (Eng. Bot. 345, and our fig. 596), they consider that the C. verisolor (fig. 596.), the C. biflorus (fig. 598. a), the C. susianus (b), the C. sulphureus (c), and the C. merarianus (d and e), with their numerous subvarieties, have been produced by culture or locality.

From the Crocus sativus, or saffron-crocus (Eng. Bot. 345, and our fig. 599. a), they think it likely that the C. seminatus (fig. 599. b) and the C. multiflorus (fig. 599. c) have been also originated by cultivation or accident.

6286. All the sorts of crocus have been, time out of mind, and still are, great ornaments to the garden; the spring sorts coming into flower in February and March, and the autumn sorts in September and October. The color of the spring crocus in its wild state, in Switzerland, is white with a purple base; it is considered as naturalised in England, but, when found wild, is almost always of a yellow color. The autumn crocus, or saffron, is also found wild in some places, and considered as naturalised; but it appears to be an African plant, which its Arabic name, sahafaran, seems to justify, and introduced originally in Edward the Third's time. Its color is generally purple or blue, as is that of most of the autumn varieties in cultivation at present.

6287. Varieties. None of these are double. Of the spring crocus, Parkinson has enumerated twenty-seven varieties; the fundamental colors of which are blue, purple, yellow, and white. Miller recites twelve as leading sorts. Mason's catalogue for 1820 mentions “twenty named sorts,” besides the light, dark, and striped purple, cloth of gold, the Scotch crocus beautifully striped, the white, the large and small yellow, and several striped sorts. The Dutch are continually producing new varieties, as are some florists in this country, of which Haworth (Hort. Trans. i. 122.) may be cited as an instance. Of the autumn crocus, Parkinson has enumerated four, and Ray six varieties. Miller has only four: the sweet-smelling, of a deep blue; the mountain, of a paler blue; the many-flowering, bluish; and the small-flowering. Most of these varieties are now lost.

6288. Criterion of a good crocus. Clear or brilliant colors, and each color distinctly marked and finely pencilled in the striped and variegated sorts.

6289. Propagation. By seed, for new varieties; and by offset-bulbs, for common
purposes. The latter generally flower the first spring after planting, and are treated in all respects as full-grown roots.

6290. By seed. The following directions are by Haworth. “The seeds of crocuses are best sown, immediately after being gathered, in light dry earth, in large pots, or pans, or small shallow boxes, with some clover- or foxglove-manure, and for the sake of retaining any adventitious moisture thin; for almost every seed will vegetate, and cover not more than half an inch with the mould. The most eligible aspect, or situation, for the seminal boxes, until the autumnal rains set in, is a moderately shady yet unsheltered one; permitting them to receive all the influence of the weather. At the approach of the latter, however, before the annual rains commence, remove the boxes to a warm aspect; and protect them from all excessive rains, frosts, and snows, by the occasional shelter of a garden-frame: allowing them, Nevertheless, the benefit of the full air at other times, but more especially after the seminal leaf (for they have but one, being monocy- toous), which is folded up in life, turgid and its fine sacculated point above the ground, in the situation of the earth. This occurs sometimes about the end of the year; but oftener in earliest spring. After this it is quite essential that they should have complete exposure to the air, even in frosty weather; sparing them nothing in the way of warmth, with loose straw under them, to prevent the frosts of frost; so as to prevent their being raised out of their infantile beds by its baneful effects. In this manner the young crocuses be treated until the sun acquires sufficient power to dry their boxes, in no case to require daily waterings. It will be then found advantageous to remove them to a cooler, but not sheltered situation, and here they may remain until their leaves die down; giving them, as just hinted, at all times, and in every situation, while their leaves are growing, such discrétion. rose- waterings, when the sun is not shining, as they may reasonably appear to require; but never until the earth they grow in becomes dry: not any whatever, after their leaves begin to look yellow. After this period, it is necessary to defend them from all humidity, except dews and gentle rains, until the end of August, or beginning of September."

6291. From weeds, worms, slugs, and snails, “it is almost needless to observe, they should constantly be kept in mind. As the surface of the earth in their boxes is occasionally stirred with the point of a knife, or fine piece of stick, it will never fail to be attended with beneficial effects, and invigo- rate the bulbs: operating no doubt, as a sort of hoicing, and, like that important practice, (as the writer of this paper conceives,) proving salutiferous to vegetables of every denomination, not only by lightening the soil, or powerful air, tendering the roots, and facilitating the soil, and stimulating their absorbent inspiration of its oxygen: without a due supply of which all vegetables, as well as animals, eventually become feeble and sick. If, notwithstanding the precaution of thinly sowing the seeds, the plants in any of your seminal boxes should have grown so thickly together as to be in danger of being thus destroyed, you may be desired to take up the boxes, delay a little more immediately further asunder in fresh earth, and about three quarters of an inch deep. But if they are not too crowded, they will require no shifting this their first autumn; but merely about a quarter of an inch of fresh mould sifted over them, previously stirring and cleaning the surface of the old from mosseg and weeds; and observing not to bury the young bulbs not yet so large as lentils, deeper than three quarters of an inch, or an inch at the most. The second season requires exactly the same manage- ment as the first. But as soon as their second year’s foliage has passed away, the roots should all be taken up. They will require now a sunny or well-drained, into fresh earth, of the same kind as before, about an inch deep, and as much apart, and treated as above. Nor does the third season demand any alteration in their management; sifting over them in autumn half an inch of fresh earth. The spring following, if they have been duly attended to, most of them will show flowers (a few, perhaps, having dropped off), and the fulcrum of leaves, fully four or five inches long, with the charming colors of their new faces all the preceding asciouity and care.” (Hort. Trans. i. 125.)

6292. Choice of bulbs. Observe that the base is not mouldy, nor the bud or summit of the bulb decayed.

6293. Soil, situation, and culture. They will grow in any common soil, but prefer a loamy sand. Octo- ber is the best season for planting; the more select varieties are grown in beds like the hyacinth, and the colors mingled in the same manner; the distance from bulb to bulb about three inches. The more ordi- nary sorts, may be planted from one to eighteen inches apart, as the importance of the bulb (fig. 552. a) They are very hardy, and require no care till the leaves begin to fade, when they should be taken up, and kept in a state of rest for two or three months. Some do not take them up oftener than once in three years, which answers very well for the border sorts. Even these, however, should not be left in the ground all the winter, but are constantly removed to the top of the pots. In the smaller sorts, they come nearer to the surface every year, till at last, if neglected, they are thrown out and lost.

6294. The bulb of the narcissus is pear-shaped and tuniciated, the leaves succulent and linear, and the flower-stems, which are from six to eighteen inches in height, bear either solitary or fasciculated flowers; the color of the flower is either white or yellow, and generally odoriferous. Most of the species are natives of the south of Europe, but one, the N. Pseudo-Narcissus, is a native of England, and common in woods in clayey soils. They come into flower in February, March, and April. 

6295. Species and varieties. The popular division of this genus is into daffodils, white narcissus, jonquils, and polyanthus narcissus. The daffodils. The common (N. Triandrus) (Hyde, the rush-leaved (N. triandrus) (Bot. Mag. 58.) and some other species and varieties.

6296. Criterion of a good narcissus. Strong erect stems; regularity of form and dis- position in the petals and nectars; distinctness and clearness of color; and in the maïzy- flowered sorts, the peduncle all of the same length, and coming into flower at once.

6297. Propagation. By seed for new varieties, but generally by offsets, which, as they

---

*Note: The text seems to be discussing the cultivation and characteristics of Narcissus, a genus of bulbous plants commonly known as daffodils.*
seldom flower the first year after separation, should not be planted with the full-grown roots, but in a bed of light loamy soil by themselves in the reserve-garden. They should not be planted later than the beginning of September.

6928. By seed. Miller directs to sow in flat pans, filled with fresh, light, sandy earth, about the beginning of August, soon after the seed is ripe; to place the pans where they will receive only the morning sun till October. Then expose them to the full sun, and protect them from heavy rains and frosts till April, when they will have come up, and must be removed to their first situation. In June, the leaves will have decayed, when some fresh earth is to be shifted over the surface of the pans. Treat them in other respects during the second winter as during the first. The end of the second summer after sowing, the roots are to be taken up and planted at about three inches' distance every way, in beds raised and rounded to throw off the water. These beds are to be protected in winter by old tan-ashes or haulm. After remaining two years in this situation, they are to be taken up and planted in others, dug deep, and with a little rotten cow-dung buried in the bottom of the fibres to strike into. Here the roots are to be planted at six inches' distance, having earth sifted over them when the leaves decay, and tan or ashes in winter. The second season of their growth in this bed, that is, the fifth from sowing, most of the bulbs will come into flower. Such as are esteemed good flowers may be taken up and treated as full-grown bulbs; but those which have not flowered, or of which the flowers are of doubtful excellence may remain another year. Miller says, none should be rejected till they have flowered two or three times: as it often happens, that their first blooming is not near so beautiful as their second and third.

6929. Choice of full-grown bulbs. Select such as are rounded towards the base rather than compressed, with full sound tops, and bottoms free from mouldiness or decayed fibres.

6930. Soil, situation, and planting. As eastern aspect is to be preferred; and, according to Miller, the best soil is fresh, light, hazel loam, mixed with a little very rotten cow-dung. The bed in which they are to be planted must be excavated three feet deep, and filled with this compost, and then the roots planted on it about eight inches' distance every way, and covered from six to eight inches, in the manner directed for tulips. The best time for planting is August, or the beginning of September.

6931. Culture. Stirring the soil, weeding, and watering are all that is in general required: but such as wish to produce a very perfect show of flowers, shelter with a awning in the manner recommended for hyacinths. In winter, the beds require the protection of tan or litter, which should be put on in October or November, and removed, and the soil stirred in February or March. Where the narcissi are cultivated for commercial purposes, the strength of the bulb is greatly increased by cutting off the flower-stem when the flowers begin to expand. The flower is still valuable, being expanded till in a marketable state by inserting the stalk in water. "Some years ago I gained admittance into the grounds of Daniel Carter, at Fulham, who has long cultivated large quantities of polyanthus narcissiæs for sale, and was surprised to find all the crop nearly gathered, though very early in the season. His son, however, explained the mystery, by taking me into a large barn, which was filled with the gathered flowers, blowing in pans of water; and he told me that by doing this, the bulbs continued to produce as abundant crops every year, as new ones imported from Holland. The practice was suggested to him by remarking, that in a bed left for seed one year, very few roots sent up a complete bunch of flowers the following season, and many roots none at all. He therefore now cuts off the stalk close to the ground, as soon as two or three of the flowers are expanded, but is very careful not to injure the leaves." (Hort. Trans. i. 322.)

6932. Taking up the bulbs. The bulbs should not be taken up oftener than every third year, if they are expected to flower strong and make a great increase. If they remain longer than three years, the offsets will become so numerous as to weaken the bulbs, which will at first flower weakly, and in time cease almost entirely to show flowers. The Dutch take up these roots every year, because their object is to furnish a round plump root, and the way to accomplish this is to take off the offsets annually, to prevent their pressing against and flattening the parent bulb. The bulbs being dried in the shade, may be laid in an airy situation in the seed-loft till wanted for planting.

6933. Storing. The bulbs some-where wetted and either in deep pots of sandy loam, or in water-glasses; their previous treatment is the same as we have prescribed for the hyacinth; and they are highly odoriferous and ornamental in apartments.

Subject. 7. Iris.—Iris, L. Trian. Monag. L. and Iridea, B. P. L'Iris, Fr.; Schwertlilie, Ger.; and Iride, Ital. (figs. 600, 601.)

6304. There are several species of Iris which are considered florists' flowers. The Persian Iris (I. Persica) (Bot. Mag., and our fig. 600 a), a very low bulbous rooted plant, blue and violet-colored flowers, greatly esteemed for their beauty and sweet smell, which is so powerful that one plant will scent a whole room. It is a native of India, and was cultivated by Parkinson in 1629. The bulbs are generally imported from Holland, and blow in water-glasses, or pots of sand with very little water, and are planted in February and March. The snake's-head Iris (I. tuberosa) (Bot. Mag. 631. and fig. 600 b) has long narrow four-cornered leaves, and a dark purple flower, which appears in April. It is a native of the Levant, and was cultivated in 1597. The tubers are generally imported from Holland. The Chiffon Iris (I. Versicolor) (Bot. Mag. 91. and fig. 600. c) has finely striated leaves, a scape a span high, and the largest and most magnificent corollas of all the species. Its petals are of a delicate texture, almost as broad as a hand, purple or black.
The bulbous-rooted, or Spanish iris (I. sibirica) (Bot. Mag. 660, 661.) of this class has been cultivated from its early days for its beauty of form and color during its whole length, and admiration for the Dutch, I. sibirica) (Bot.

6305. Culture of the first three species. These seldom ripen their seeds in this country, nor are they often propagated here from offsets, annual supplies of bulbs being obtained from Holland, and generally forced like the hyacinth. Justice says, "Brit. Gard. Direct. 222." the Dutch florists told him, that they never could obtain any varieties from sowing the seeds of the Persian iris; nor could this author himself, who cultivated the plant, and raised seedlings at Crichton, near Edinburgh, with great care and considerable success.

The seeds are three best cultivated under the protection of a frame, where their flowers will be less liable to injury than in the open air, and where their leaves will be stronger and more able to nourish the bulbs and offsets. The Chalcedonian iris, Curtis observes, thrives best in a loamy soil and sunny exposure, with a pure air, but guarded from moisture, and from frosts during winter. The Persian iris thrives best in a light sandy loam and eastern exposure, sheltered from rains and frosts, like the other. The snake's-head iris is the hardest of the three, requires the same soil and exposure as the Persian, but less care during winter. None of these sorts need be taken up oftener than once in three years, when the leaves decay; they should be replanted in a month or six weeks afterwards, at six inches' distance every way, and covered from two to four inches according to the size of the bulbous tuber. If the soil in which the bulbous and tuberous sorts of iris is planted be loose and deep, and the plants not taken up every three, or at most four years, they will run down and be lost.

6306. Culture of the bulbous irises. Miller and Justice recommend a light sandy loam, not rich, and an eastern exposure. The plants are multiplied abundantly by offsets, and as they also produce seeds freely, many new varieties are obtained in that manner. Justice says, "I know of no flower that better repays the time and trouble of culture." These are the author's directions for its propagation by seed.

"In August the seeds become ripe, and are plentifully produced on all seedling plants, although, like many other plants, but sparingly, and very frequently not at all, on such as have been long increased by offsets. If, by way of experiment, they are sown in shallow drills, about one inch deep, and in the March following, they will make an appearance very similar to rows of young onions. With no other care than frequent weeding, they may remain in the seed-bed for three years, for they are much more Hardy than most kinds of seedling bulbs, and, therefore, will not even require protection from the frost of the first winter. It will be necessary to take them out at one foot's distance, row by row, and the bulbs six inches apart; and in two years from their removal, most of the strongest will show blossom, and nearly all in the following year, or the sixth from the seed. If, during the time the roots are at rest, the top surface of the earth is carefully removed, and fresh light loam is substituted, a year will be saved, for this treatment will greatly promote the growth of the bulbs, and with these, as well as many other seedling plants, it is not a stated time that must pass before they blossom, but only such a portion as will allow the bulb to attain a size sufficient to contain vigor to produce and perfect a flower-stem, the rootforming being in the summer. When they blossom, a selection can be made, and the varieties perpetuated by the increase of their offsets. The most proper time for removing the bulbs is in August and September, but those kept out of ground till Christmas rarely blossom in the succeeding summer." (Hort. Trans. iv. 141.)

6307. Flowering bulbs. Every third year, in August, is the most proper time for taking them up, and they should, if possible, the bulbs planted. Masters says, those kept out of ground till Christmas rarely blossom in the succeeding summer. They may be planted either in about six inches asunder, as soon as ripe, or in mingled borders, care being taken in each case to prevent the roots running down by removal every third year, or by a substratum of tiles or compact rubbish within eighteen inches of the surface. These species are very hardy, and flowering so late as June, require no protection either in summer or winter. They are seldom or never forced.

6308. Of the Fritillary there are three species which are considered as florists' flowers; of these species there are numerous varieties.

The crown-imperial (F. imperialis). (Bot. Mag. 194.) Le Corneous Imperialis, Fr.; Kaiser-rhemen, Ger.; and La Corona Imperialis, Ital.) (fig. 602 a.) has a scaly bulbous-rooted, with a few extended from two to four feet in height, furrowed, and with a purple, a yellow, a green, leaves, and crowned with a white, a yellow, a scarlet, a purple, a low, red, or striped in various ways, which appear in March and April. It is one of the earliest flower-garden of flower-garden, producing a fine apartment of color; it bursts into flower at a season when flowers are most wanted. The "imperial carpet," Professor Martyn observes, "cannot but engage the attention of the curious observer. None are more suitable than these as the base of each petal, and has a drop of limpid nectarous juice standing in it, when the flower is in vigor. Another of the wonders of nature may be observed in the peduncles which bend down and rest on the earth, a plant in flower, but become upright as the seed ripens." There is a great variety in cultivation, distinguished by the different shades of yellow, white, and red, in the flower, and by being striped double or semi-double. The crown-imperial (F. imperialis) (Bot. Mag. 1557, and fig. 603 b.) has a large, globular bulb, the size of an orange; the stem is three feet high, and the flowers in a loose spike at the top, forming a pyramid. They are of dark purple color, and appear in May, but seldom produce seeds in England. It is a native of Persia, and was cultivated here in 1596. There is a smaller variety, with a shorter stem, and smaller leaves and flowers. The common fritillary, or chequered lily, (F. Meleagris, (Bot. Mag. 660.) La Fritillaire Meleagre, Fre. Keesbey, Ger.; and Giglio variegato, Ital. (fig. 603.) a) has a solid tuber, about the size of a nut, a stem from twelve to eighteen inches high, with linear leaves, and one or more pendulous flowers on the top of the stem. It is a native of Britain, and flowers in April and May, or in March in mild seasons. There are nearly twenty varieties, with red, white, purple, black, striped, and double flowers, besides an umbelate fritillary, a bulb between this species and the crown-imperial.
6309. Propagation. The common method is by offsets; but they may be raised from seed, which ripens readily, and is to be treated in all respects like that of the tulip, the seedlings of the crown-imperials are raised of the fifth or sixth year, and those of the others the third. The common method is by offsets; and these are removed in May or June, and they should not be kept longer out of the ground than two months.

6310. Of the lily there are sixteen species introduced in Britain, and of the whole may be reckoned very choice flowers. We shall notice particularly, only those species, of which numerous varieties have been produced. These are:

The white lily (L. Candidum) (Bot. Mag. 378) has a bulb, a leafy stem, from three to four feet in height, terminating in large pure white flowers on peduncles. It is a native of the Levant, and was in most gardens in the latter part of last season. Of this species, there are eight or ten varieties and sub-varieties.

The martagon, or Turk's cap, (L. Martagon) (Bot. Mag. 855), has a large scarlet martagon bulb, a stalk, covered with narrow linear leaves, near three feet high and terminating peduncles; the scarlet flowers in July. Of this species are half a dozen varieties, besides the scarlet martagon (L. Chalcedonum), and the magnificient, (L. Arum), and flowers, (L. Liripetala). Besides the above species and their varieties, there are the L. Candidum, ice-lily, L. Vermeulis, or Tiger lily; the L. 없다, or Japan lily, with stems of 5 feet, and the flowers 7 inches broad, pure white with a streak of blue; all equally meriting cultivation as select flowers.

6312. Propagation. This is almost always by offset-bulbs; but new varieties may be raised from seed, which ripens in most sorts in August: being treated as directed for raising new varieties of the narcissus, the young bulbs will flower the fourth and fifth years.

6313. Culture of flowering bulbs. The more common sorts, species, and varieties, will thrive in any soil and situation, even under the shade of trees. The Canadian, Pomponian, and Philosopher martagons are somewhat tender, and require the protection of ashes or rotten bark in winter. They are generally planted in borders, and need not be taken up oftener than every three or four years in September, and replanted whenever the bulb is half broken if the species follows in the same spot after they have passed leaves, without weakening them so as to prevent their flowering for several years. This remark, indeed, will apply to most bulbous-rooted plants. Griffin, of South Lambeth, whose superior skill in the cultivation of bulbous plants is well known (Hort. Trans. iv. 544.), has been in the practice of keeping the Lilium japonicum in pots, protected by a strong-frame, for three years; but he thinks they thrive best in the former. He places the bulbs in twenty-four-sixed pots, not lower than an inch from the surface of the mould, which is composed of about two thirds peat and one third loam, the bottom of the pot being filled with a inch, with siftings of peat. The plants are kept entirely from frost, and are watered very little when in a dormant state, for they are then very impatient of wet in excess. The pots kept in the green-house are placed at a distance from the flame to prevent the mould drying quickly. (Hort. Trans. iv. 544.) Brooks grows in a brick-pit, which he says, the bulbs or glassed in cases there are too; but they are equally applicable to all exotic bulbs. Bulbous roots increase in size, and proceed in acquiring powers to produce blossoms, only during the periods in which they have leaves, and in which such leaves are exposed to light; and these organs always operate most efficiently when they are young, and have just attained their full growth. The bulb of the Guernsey lily, as it is unjustly called, either produces leaves till September, or the beginning of October, at which period, the quantity of light afforded by our climate is probably quite insufficient for a plant, which is said to be a native of the warm and bright climate of Java, and before the return of spring, its leaves are necessarily grown old, and nearly out of office, even when they have been safely protected from frost through the winter. It is, therefore, not extraordinary, that a bulb of this species, which has once expanded itself in affording flowers, should but very slowly recover the power of blossoming again. Considering, therefore, the deficiency of light and heat, and period of ripening, at this time of year, of the lily, (and from the observation of the flowers, I inferred that nothing more would be required to make it blossom, as freely, at least, as it does in Guernsey, than such a slight degree of artificial heat, applied early in the summer, as would prove sufficient to make the bulbs vegetate a few weeks earlier than usual in the autumn. Early in the winter, when the temperature of the preceding autumn, was subjected to such a degree of artificial heat, as occasioned it to vegetate six weeks, or more, earlier than it would otherwise have done. It did not, of course, produce any flowers; but in the following season it blossomed early, and strongly, and...
afforded two offsets. These were put, in the spring of 1818, into pots, containing about one eighth of a square foot of light and rich mould, and were fed with manured water, and their period of vegetation was again accelerated by artificial heat. Their leaves, consequently, grew yellow from maturity, early in the present spring, when the pots were placed in rather a shady situation, and near a north wall, to afford us an opportunity of observing to what extent, in such a situation, the early production of the leaves in the preceding seasons had changed the habit of the plant. I entertained no doubt but that both the bulbs would afford blossoms, but I was much gratified by the appearance of the blossoms in the first week in July. From the success of the preceding experiment, I conclude that if the offsets, and probably the bulbs of this plant which have produced flowers, be placed in a moderate hot-bed, in the end of May, to occasion the early production of their leaves, blossoms would be constantly afforded in the following season, but only if the bulbs are absolutely to be ventilated at night, as soon as they are nearly fully grown, and to protect them from frost till the approach of spring."

6316. The Rev. W. Williamson has adopted the same rationale as Knight; and, with the aid of a glass frame, without artificial heat, brought bulbs which had flowered into a state to flower again after two winters. In the absence of artificial heat, he thinks one winter might probably have been sufficient. (Hort. Trans. iii. 450.)

6317. The Hon. and Rev. W. Herbert has found a similar treatment attended with corresponding success. He says, "the only attention which the Guernsey lily requires here (Suffolk, Yorkshire), is to give it sufficient air while the leaves are growing, that they may be strong and dark-colored; to protect the leaves from frost, keeping the pots near the light, if under glass; to give a moderate and regular supply of water, and to leave the bulbs nearly dry, from the time the leaves decay, that is, about mid-June. At this time the flower-buds should be removed. If the bulbs are dry early in the summer, the autumnal shoot will be delayed till the season becomes too cold for the proper growth of the flowers or leaves, and the natural course and vigor of the plant will be interrupted, after which it will require at least a year to repair the injury it will have received. Whenever the sprouting of the bulb is tardy, it should be assisted by placing it, for a short time, in a warmer situation. If the stigma does not expand so as to become, after a few days, trident, it is a sign that the temperature is too low to suit the plant, and the leaves will probably not push freely without more heat. I have obtained seed from the Guernsey lily by procuring the blossom early in an airy situation, and pushing down the soil Herbert recommends for manure; he says "they will thrive in the most wholesome compost, which does not canker their bulbs. They should be planted partly above ground, for the earth round their necks will prevent their flowering or thriving, and will even sometimes destroy them."" The Guernseys, with very few exceptions, he adds, suit the whole of the bulbs included under amaryllis, as well as a number of other allied genera, as hennanthes, pantanatum, agapanthus, &c. Some species of these genera, as Armarylis longifolia, W. and Crinum Asiati-
cum, Rox., are natives of dry ditches that communicate at certain seasons with the water of the rivers in Bengal, where they rooted deeply in the mud. These species, and some others, Herbert found to succeed perfectly when plunged during summer in a pond. "Most of the crinums," he says, "are swamp plants, or grow in river-mud, and should be cultivated in our stoves, with a pan of water under them, the bulbs being raised above the earth, and stripped of all dead integuments. Agapanthus and pantanatum flowers but when so treated; the Amarylis longifolia (which, he says, should be named Crinum capense) will," he has no doubt, "flower as a hardly aquatic, if planted in any pond or river of two feet water, not liable to freeze at the bottom." (Hort. Trans. iii. 188.)

6318. The account of the occurrence of the Guernsey lily in the Island of Guernsey is given by Dr. Maccul-
loch (Caled. Mem. ii. 62) : there they grow in the open air, and protect it with sand during winter.

Subsect. 11. Ixie and Gladiator, W. Trian. Monog. L. and Iridea, B. P.

6319. The ixie and gladiolus include a number of recently formed genera (see Bot. Mag. and Bot. Reg.) of Cape bulbs, which may be flowered in the open air, under frames without bottom heat, or on shelves near the glass in green-houses. The Hon. W. Herbert, who has paid great attention to the culture of bulbs, is "persuaded that the African gladiolus will become great favorites with florists, when their beauty in the open border, the facility of their culture, and the endless variety which may be produced from seed by blending the several species, are fully known, nor will they be found to yield in beauty to the tulip and ranunculus."

(Hort. Trans. iv. 154.)

6320. Propagation and culture. They may either be propagated by seed or offset-bulbs; by the former mode, Herbert has produced numerous beautiful varieties. The proper soil for these and similar bulbs is peat with sand : and in a bed of this compost the seeds should be sown in spring, and well watered before and after, they come up. At the beginning of October, the young bulbs should be removed. If the young bulbs should be taken up and dried; they may be replanted again at any time, placing them about eight inches under ground, to prevent the frost reaching them. Next year they will generally flower. "The best way of treating gladiolus which are to be flowered in pots is, whenever the bulbs are potted, to plunge the pots into water, and when once they have flowered, and raise them nearer the surface in spring, as soon as the very severe frosts are over ; or not to plunge them so deep, and protect them with moss, leaves, rotten tap, &c.

6321. Various other bulbous iridace, and also oxalis, lachenalia, cyclamen, &c. may be successfully treated in a similar manner. (Herbert, Hort. Trans.; Maddock, Flor. Dir.)

6322. The tuberosa is a bulbous-rooted plant, with linear leaves of a whitish green, and stuns four or five feet high, terminating in a sparsc spire of white flowers, of very powerful fragrance. It is a native of India, whence it was first brought to Europe about 1524; and to England in 1629. It is generally cultivated in frames or the green-house, but in warm situations will flower in the open air. The tubers of this plant are annually imported from the warm provinces of North America and Italy, but, like those of the Guernsey lily, might, by proper treatment, as Salisbury has proved, be produced in this country equally fit for flowering. There is a double variety, which is in most esteem, but both are equally fragrant.

6323. General treatment. The bulbs are planted in pots of sandy loam in March or April, and brought forward in a hot-bed or hot-house till the flower-buds begin to ap-
PRACTICE

The plants are then removed to the green-house or the open air, or to halls or churches, as in Italy, where the cooler temperature procures a prolonged bloom.

6324. Culture to produce flowering roots. The following is the process followed by Salisbury, by which he produced, for many years, in the open air at Chapel Allerton, flowering bulbs equal to those imported. The situation he preferred was a dry warm border; in this he made an excavation two or three feet deep, and of any convenient length and width; about the middle of April, he filled this pit with fresh stable-dung, and covered it with light sandy earth; then, on the bed so formed, the small lateral roots, or those from foreign bulbs, or from those which had flowered in this country the preceding year, and been preserved through the winter in sand, were planted at five inches' distance every way, the upper part of the tuber being just covered with earth. The bed was protected from nightly frosts and heavy rains, little or no water was given, but when the leaves were an inch long, a little fresh compost was added to the surface. In June and July, when the leaves were in full vigor, it was watered copiously after warm days; but in autumn and the beginning of winter, it was carefully protected from heavy rains. In the beginning of December, the decayed leaves being removed, the bed was thatched over a foot thick with dry dung, and covered with a foot of wet, or covered with a frame and litter. In February the roots were taken up, preserving their fibres, and packed in dry sand in a cellar where the cold could not penetrate, till April, when their fibres being shortened in proportion to their decay, and all the offsets excepting one or two on each bulb being removed, they were replanted as before. A few strong roots flowered in the bed, and in the succeeding spring, they were to be transplanted in September to other beds as required, beds of flight from the roots were taken up for forcing, or of any of the purposes for which tuberose-roots are grown. By this process bulbs were produced equal, if not superior, to those imported; and therefore the author thinks their culture might become an object to the commercial gardener, especially in the southern counties near the sea, and in the vicinity of London. The great object, he says, is to obtain "a sufficient degree of heat in summer to bring their leaves out to their full magnitude, that of the roots following of course. The theory," he adds, "which I would recommend any intelligent gardener to adopt in its general management is, to keep the roots growing as vigorously as possible from May to October, but in a state of complete rest and drought for the remainder of the year." (Hort. Trans. i. 53.)

6325. Most of the species of peony introduced in this country may be considered as select flowers; but that which has been longest cultivated is the P. officinalis (Bot. Mag. 1784). The roots are composed of roundish tubers, the stalks of the leaves rise between two and three feet high, and terminate in large red or purple flowers, which appear in May. The leaves are composed of many unequal lobes, variously cut into many segments. It is a native of Switzerland, Dauphine, and other parts of Europe, and also of China and Japan; and was cultivated here in 1562. The roots were formerly much used in medicine.

6326. Varieties. Originally the common peony was said to be of two sorts, male and female, the flowers of the former being smaller and lighter colored than those of the latter. These distinctions, which had no sexual allusion in this case, the peony being hermaphrodite, are now laid aside, and the varieties of P. officinalis have been reduced by Sabine (Hort. Trans. ii. 273.) to the following:—

| The double red or the most common, and formerly highly prized; being, when introduced at Antwerp, near 360 years ago, sold for twelve crowns. | The double flesh-colored Chinese | The double white | The double striped Chinese | The double sweet-scented Chinese (Hort. Trans. vol. ii. pt. 15.) | Whitley's double white Chinese |

6327. Propagation and culture. By seed from the single and semi-double sorts for new species, and by dividing the roots for ordinary purposes. Miller directs to sow the seeds which ripen in September, immediately afterwards in light fresh earth, covering them half an inch. They will come up the following spring, and may remain in the seed-bed two years before they are transplanted, sowing a little rich earth over them when the leaves decay at the end of the growing season. Having made two years' growth in the seed-bed, they are to be transplanted in September into well-prepared beds of flight from the roots; and placed six inches asunder every way, and three inches deep. Here they are to remain till they flower, which is generally the fourth or fifth summer after sowing.

6328. Tuberous roots are readily propagated by parting, taking care to preserve a bud on the crown of each offset. The plants are very hardy; they will grow in almost any soil and situation, and even under the shade of trees, where, Miller says, they continue longest in beauty. They are chiefly planted in flower-borders, and form a splendid ornament both to the parterre and shrubbery.

6329. The roots of the Dahlia are tuberous and fasciculated; the stems rise from five to eight feet, covered with large compound leaves, resembling those of the common daffodil, elder, and with side branches bearing numerous flowers of a great variety of colors, which appear in August, and continue till destroyed by frost. The plant grows wild in Mexico, in sandy meadows, and was sent to Madrid in 1789, and thence to England in the same year; but the plants being lost, seeds were reintroduced by Lady Holland in 1804, and from these and some plants imported from France during the peace of 1814, the present extensive stock of dahlias has originated. Till this last period they were much more cultivated in France and Germany than in England, and more especially by the Count Lelieur, at Paris, and Otto, at Berlin. At present the dahlia is the most fashionable flower in this country, and the extent of its culture in some of the nurseries, especially that of Lee, is truly astonishing. Nor is this to be wondered at, as Sabine observes, for, independently of the great beauty and diversity of the
flowers, they are in perfection at a season when, till they came into notice, our gardens had but little ornament. The roots are edible, but not agreeable.

6330. The varieties are exceedingly numerous.

The leading varieties of the fertile-rooted species are the purple, pale, white, sulphur, yellow, tawny, copper, brick-red, dark-red, pomegranate, scarlet, crimson, crimson and white, and lilac flowered single, semi-double, and double, with innumerable sub-

6331. Criterion of a good dahlia. The plant short, stiff, and bushy, prolific in flowers having short peduncles; the flower well expanded and standing boldly to the view, and the colors clear and distinct.

6332. Propagation. By dividing the roots, and by cuttings for ordinary purposes; and by seed for new varieties and also for increasing the stock of this plant, as the seedlings flower the first year. In dividing the root care must be had to preserve a bud to each section, otherwise, though the tubers will throw out roots, they will not produce leaves.

6333. By cuttings. To take from the root-shoots in spring, or the tops of the young shoots, as early in summer as may be; cut the lower end smoothly off in the middle of a joint, and leave the leaves on the top, excepting such as would be buried in planting the cutting. Plant in sandy earth on heat, and cover with a hand-glass, and they will strike and produce both flower and tuber before the autumn.

6334. By grafting. This mode of propagating herbaceous vegetables has been known for some time on the continent, and practised, as we have seen (2522), to a considerable extent by the Baron Tschoudi. In this country it seems to have been first adopted by Blake, in 1830, as a more speedy mode of propagation. The following is the practice: “The cutting intended for the graft should be strong, and short-jointed, having on it two or more joints or buds; it must be also procured as soon in the season as possible; when obtained, select a good tuber of a single sort, taking especial care that it has no eyes; with a sharp knife (for a dull edge will not do), cut off a slice from the upper part of the root, making at the bottom of the part so cut, a ledge whereon to rest the graft; this is recommended because you cannot tongue the graft as you do a wood-shoot; and the ledge is useful in keeping the cutting fixed in its place while you tie it; next cut the scion sloping, to fit, and cut the ledge of the root; with an instrument on the above ledge, start a graft on the under side, without the ledge, provided the graft can be well fixed to the tuber, but the work will not then be so neat. It is of advantage, though not absolutely necessary, that a joint should be at the end of the scion, but it is not necessary, nor will it affect the cutting, if you have no more than one joint, or if  the graft is done at the top of the cutting, and the scion put forth new roots from that lower joint; the stem is formed from the upper joint. I therefore procure the cuttings with the two lower joints as near together as possible. After the graft has been tied, a piece of fine clay, such as is used for common grafting, must be placed round it; then pot the root in fine mould, in a pot of such a size as will bury the graft half way in the mould; the cutting may be placed in a number of pots, if you chance to have the scion in a number of clones. To have the work in time; I prefer the front for the greater convenience of shading and watering which are required. A striking glass may be put over the graft, or not, as you please. In about three weeks the root should be shifted into a larger pot, if it be too soon to plant it in the border, which will probably be the case; for the work was begun in March, the plant cannot go out till the end of May, so that the shifting will be very easy to promote its growth till the proper season of planting out shall arrive.” (Hort. Trans. vol. iv. 476.)

6335. By seed. The following directions are extracted from an excellent paper on this subject (Hort. Trans. vol. 238.) by Sabine. Collect the seeds in September from the dwarf plants, where no preference exists on other accounts, and from semi-double flowers when double varieties are chiefly desired. Perhaps seeds obtained from those particular florists of the disc which have altered their form, may have seen better results. If you wish for both double and single forms, if you chance to have a heat of 55° or 60°; the young plants to be pricked out, if necessary, in pots, and kept in a moderate temperate, say 50° or 55°, till the end of April. Now plant out where they are to remain, covering each plant at night with an empty pot for some weeks, to avoid injury from spring frosts. If in a compartment by the time that the frost is off, and at two feet from the border, plant in the border in the back rows. In either case they require to be staked. Seedlings thus treated will blow in July, and continue in perfection till the autumn; but the first frost takes the same effect on the Dahlia as on the potato, and as the white frost of November. A blow may be prolonged by planting in large pots and removing early in autumn to the green-house.

6336. Soil and situation. Dahlias thrive best in rich loam, and a clear open space, neither sheltered by trees or walls. Like the potato, they exhaust the soil considerably, and do not thrive well when repeatedly planted on the same spot.

6337. Planting full-grown roots. These may either be planted on the spot where they are to flower, early in April, and protected by covering with litter or by empty pots, as in transplanting seedlings; or, which is more rare, if fallow, they may be planted in large pots and forwarded in frames or pits, or in any spare house, with a temperature equal to that of the green-house, till the middle of May, when they may be planted where they are finally to remain, and will flower in June. Sabine says, “Dahlias look best in a large mass, unmixed with other plants; in this plan of growing them, some neatness is required in the effect of the mass, and the mixture of colors; and particular care is necessary to keep the tallest plants either in the centre or at the back of the clump, according as it is destined to be viewed, from one side only, or all sides, and to place the whole so that there shall be no unceveness in the general shape of the entire mass, arising from the irregular arrangement of the plants according to their respective heights. The roots should be planted about three feet from each other every way; this distance will keep each sufficiently distinct, and yet so united that the whole clump will have the appearance of an unbroken wood or forest of dahlias. They look very handsome if planted in the manner of an avenue, in a straight line, on each side of a walk.”

6338. General culture. No particular care is requisite after the plants are neatly tied to stakes, till they have been attacked by the frost, they should then be cut down and the roots covered with as much dry straw as will keep them from the frost. One of the most important operations, old and young, will be necessary to keep the frost from the tubers of a potato-plant left in the soil. If this is done, they will blow down and early next season. But the most general way, especially with the valuable sorts, is to dig up the roots with a portion of the stem attached, and plant or bed them in pots, and then, among others, keep them until the stage of a green-house, or in some dry airy place, free from the access of frost till the springing. On a large scale, they are treated like potatoes, or packed in ridges with sand in cellars, and covered with straw; the object being to keep them sufficiently moist and plump to maintain the living principle, and yet not to rot them, or have them destroyed by frost.
Subsect. 15. Auricula. — Primula Auricula, L. (Jac. Aus. 5. t. 415.) Pent. Monog. L. and Primulaceae, B. P. Oreille d’ours, Fr.; Aurikel, Ger.; and Orecchio d’oro, Ital. (fig. 603.)

6339. The auricula is a flower of great beauty: it is a small fibrous-rooted plant, with fleshy succulent leaves, generally nearly on the edges; a native of the mountains of Switzerland, Austria, Syria, and the Caucasus, &c. We have gathered it in abundance near the post-house on the Simplon road. It was cultivated by Gerrard in 1597, under the name of bear’s ears, or mountain cowslips. To show what cultivation may perform on this plant, Professor Martyn relates, from Morant’s Colchester (1768, p. 92.), that Henry Stow, a gardener, near that place, a famous grower of auriculas, had some plants with no less than 133 blossoms on one stem. About a hundred years ago the passion for this flower in England was much greater than at present; and, as Justice remarks, we supplied the Dutch, who afterwards, till the late war, used to re-supply us with the progeny of our own flowers. Justice was the most enthusiastic cultivator of the auricula, and indeed of all florists’ flowers of his time. After him the Lancashire growers are the next to be distinguished, and more especially Maddock, the well known author of the Florist’s Directory, originally from Warrington. Emmerton is, at this time, one of the most enthusiastic admirers of this flower; and the best collections are to be found among the commercial gardeners near London, and the operative manufacturers and artisans near Manchester, Paisley, and other large towns. It is like the tulip, pink, &c., a poor man’s flower, and a fine blow is rarely to be seen in the gardens of the nobility and gentry.

6340. The varieties are endless.

The colors of the flower in its wild state are yellow, purple, and variegated. (Gerrard figures the yellow, purple, red, scarlet, blush-colored, and white, red, most of which grew in the London gardens in his time. Parkinson, in 1629, enumerates twenty varieties, and says many more were to be found. Rea, in 1702, has an increased number, classed as purples, reds, yellows, and whites. In 1798, the catalogue of J. Maddock contained nearly 900 named varieties, divided into ligulées, selves, or plain one-colored sorts, double flowers, and painted or variegated sorts. The latter only are held by extenuists, and few collections contain more than two or three sets of the fundamental colors, and as many double flowers. Double varieties are not in extenuism.

6341. Criterion of a fine variegated auricula. (fig. 603. a, b, c, d, e) "The stem should be strong, erect, and elastic, and of a proper height, that the bunch or truss may be above the foliage of the plant. The peduncles, or foot-stalks, of the flowers should also be strong and elastic, and of a proportional length to the size and quantity of the pips, which should not be less than seven in number, that the bunch may be rather round, close, and compact. The component parts of the pip are the tube (with its stamens and anthers); the eye; and the exterior circle containing the ground-color, with its edge or margin: these three should be all well proportioned, which will be the case if the diameter of the tube be one part, the eye three, and the whole pip six, or nearly so. All the admirers of this flower agree that the pips ought to be round; but this seldom happens; and we must be content if they are so nearly round as not to be what is termed starry. The anthers, or summits of the stamens, ought to be large, bold, and fill the tube well, and the tube should terminate rather above the eye; the eye should be very white, smooth, and round, without any cracks, and distinct from the ground or self-color. The ground-color should be bold and rich, and equal on every side of the eye, whether it be in one uniform circle, or in bright patches; it should be distinct at the eye, and only broken at the outward part into the edging; a fine black, purple, or bright coffee-color, contrast best with the eye; a rich blue or bright pink is pleasing, but a glowing scarlet or deep crimson would be most desirable, if well edged with a bright green; but this must seldom be expected. The green edge, or margin, is the principal cause of the variegated appearance in this flower; and it should be in proportion to the ground-color, i.e. about one half of each. The darker grounds are generally covered with a white powder, which seems necessary, as well as the white eye, to guard the flowers from the scorching heat of the sun’s rays, which would soon destroy them if they were exposed to it."

6342. Propagation. By rooted slips, or dividing the root for continuing approved sorts, and by seed for obtaining new varieties. The best time for taking off slips, or dividing the root, is after the plant has done flowering and ripening its seed, if this last
is permitted. The operation is therefore generally performed in July and the beginning of August. Emmerton says, the Lancashire growers will not take, or sell a slip before the 5th of August, on which day they begin to execute orders for young plants.

6343. By sod. Maddock says: "The surest and best method to obtain fine auriculas from seed is to provide young, healthy, and strong plants, of the respective species or varieties; these, on the approach of bloom, should be detached from the rest to a remote part of the garden, and there exposed to the sun, and rain, while the last is in moderation; but if in excess, they should be preserved from it by mats on hoops, or small hand-glasses may be placed over them. In dry weather, this will be necessary. The plants will appear to much advantage when in full flower, in tention to this particular point." Emmerton is a warm advocate for raising the auricula from seeds, and says, any one who will follow his directions may be certain of raising very fine sorts. He selects the flowers of the highest quality, and if the fair sex are desirous of them in the spring, he advises them to plant the following sorts, sufficiently well known to the London and Manchester florists, and to transplant them in pots; six plants of two sorts in each pot, viz.:

For breaking light-green or gray-eyed seedlings. A pot with 2 of Barlow's king; 3 of the same; 1 of Barlow's king, and 4 of Butterbury's Lord Hood; one with 3 of Barlow's king, and 2 of Keny- ringer's seed.

For breaking the green-eyed or gray-green-eyed seedlings. Pots with six plants each, viz. 3 of Barlow's king, 5 of Poiite's Highland boy; 3 of Barlow's king, 5 of Buckley's jolly tur; 5 of Barlow's king, 3 of Van rhijn's Prince Blucher; 5 of Barlow's king, 3 of Stretch's Emperor Alexander.

For breaking fine choice-tinted violet ground colored seedlings with green edges. One with six plants each, viz. 5 of Barlow's superb, 5 of Be- ren's victory; 5 of Beez's super; 5 of Warrie's Prince Blucher; 3 of Pearless's superb, 3 of Chilcot's king.

6344. Each of these pots is to be set apart, and at a distance from all other auriculas, before the flowers have expanded, to prevent accidental impregnation, and to be kept so detached till auriculas in general are out of flower. They may then be placed on a platform of scoria or tiles, where there remain to ripen their seeds.

6345. The soil or mode is to impregnate the stigma of one sort with the anthers of another, in Knight's manner: or even without castrating the female parent. Nicol tried this last mode with the greatest succe both in the primula and dianthus genus. (Cited. Hort. Soc. Mem. ii. 276.)

6346. The seed will commonly ripen in June and July, and to be gathered in single capsules as it ripens, and to be carefully preserved in a cellar or Potting-house according to Maddock; and from the middle of February to the 10th or 12th of March, according to Emmerton. Maddock sows in boxes, covering as lightly as possible, and sets the boxes in a hot-bed; preserving a moderate and equal degree of warmth for the duration of the seed, and from then on giving every live grain into vegetation in about three weeks, if the warmth of the bed be properly kept up; by which, more usually mode of exposure to the open air, the greater part does not vegetate till the second year; and the weaker seeds, which are probably the most valuable, seldom vegetate at all.

6347. The seed must always be kept moderately moist; but never very wet; the best method of watering it is by means of a hard clothes-brush, dipped into soft water, which has had its chill taken off by standing in the sun, the hair being quickly turned upwards, and the hand rubbed briskly over it, will cause the water to fly off in an opposite direction, in particles almost as fine as dew; a sufficient watering in this manner, in this case, is given in a few minutes. If the surface of the earth in the box is inclining to become mousy or mouldy, it must be stirred all over very carefully with a pin, about as deep as the thickness of a shilling. At the expiration of three, four, or at most, five weeks, the young plants will all make themselves plainly known; with them very carefully separate the plants, and render them fit for an entire exposure to it, which they will be able to bear in a fortnight or three weeks afterwards, at which time the box should be taken out of the frame, and placed rather in a warm situation, though not too much exposed to the sun, till towards the end of April, when it may be again removed into the frame, and the sun given to them very gradually; and in May, when the weather is hot, it should be placed in the most cool and airy part of the garden, not neglecting, at any time, to keep the earth moderately moist; but at the same time preserving it from violent rains when ever they occur. As soon as any of the plants appear with six leaves, such should be taken out of the rest, and placed in their separate pots; or let them be transplanted into compost, to which they will soon become accustomed to; and when they are again grown, so as nearly to touch each other, they may be a second time transplanted into larger boxes, or round small pots, at the distance of three or four inches, where they should remain till it becomes proper to transplant them into larger pots, if they have acquired any considerable size; and then such as appear to possess of merit should be marked, and the inferior ones destroyed. As soon as the bloom is over, such as have been marked should be taken up, and planted separately in small pots, and be taken the same care of as other auriculas, till they blow again; at which time if the auriculas and properties may be ascertainment with precision. Such weakly plants as are not able to blow the first or second year, ought nevertheless to be carefully preserved; for amongst these it often happens that the most valuable flowers are found. A great proportion of the seedlings, although the seed was saved from the best flowers, will be plain-colored, or self, which, unless possessed of excellent properties in other respects, or being singularly beautiful in their colors, are of no value, but as common border-flowers.

6348. Emmerton says in small pots, about six inches over the top, and six deep, filled half full with coalashes, and the remainder with the sort of earth which is in the form of a bell-glass, and then puts on a bell-glass, and places the pots in a situation quite excluded from the sun, except in the morning. The bell-glass, he says, will cause the seed to vegetate much sooner, and by pouring the water over the top of it, the earth in which the seeds are will receive sufficient moisture, so that there will be no occasion to touch them. He says, that he has extensively used this method, and recommends it for the seed-pots to be placed in, but by no means a hot-bed; or if not that accommodation, a hand-glass, having tiles or plates placed underneath, to keep the worms out of the pots; great care being taken to keep the earth in a regular moist state. In about four or five weeks, perhaps three weeks, if in a green-house, the seeds will break green; and will be ready to be thinned to appear about the 1st of August, and to be planted in the open air, at the 1st of September, in boxes or sols of earth.

6349. Hogg says, auricula-seed may be sown either in pots, or in the open air, about the 1st of March, and covered with a hand-glass. When the plants will bear transplanting, he removes them into pots of the smallest size, one in a pot.

6350. Soil. The different composes used by florists in growing this flower are as numerous, Hogg observes, as the florists themselves. "Persons often take extraordinary pains, and incur unnecessary expense, to injure, if not destroy, their flowers. Weak minds are soon misled by quackery and novelty, having no sound judgment of their
own; and quackery, even in the growing of flowers, has as many followers as in any other line.” *(Treatise, &c. p. 103.)

6531. Maddock recommends “one half rotten cow-dung, two years old. The cow-dung produces near London is more crude and worse than that of the country, occasioned by the difference of food on which the animal subsists; it is therefore necessary longer preparation and exposure to the atmosphere that the latter, but two years and a half will be found sufficient for it in its grossest and most crude state. One sixth of the yard, earth, of an open texture. One eighth earth of rotten leaves. One twelfth coarse sea or river sand. One twenty-fourth soft decayed willow wood. One twenty-fourth peaty or moory earth. One twenty-fourth ashes of burnt vegetables.” This compost is to be thoroughly incorporated and exposed to the air for a month for ventilation for several nights, it may be spread over two yards.

6532. Emmerton says, “Good compost is the food, the very life of the auricula;” it must be very rich, and properly tempered and sweetened by the sun, frost, and air. His materials are goose or pigeon droppings, night-soil, sugar-bakers’ scum, yellow loam, or loam from such land as will grow good crops of wheat, and sea-sand. night-soil of all kinds which are, no doubt, supplied by sugar-bakers’ scum, that substance being chiefly blood, lime-water, and oily matter. He gives various proportions, all of which he has found successful; in some, night-soil and sand are wanting, thus: three barrowfuls of goose-dung, steeped in blood from butchers; three barrowfuls of sugar-bakers’ scum; two barrowfuls of fine yellow loam; or: one barrowful of horse-dung; two barrowfuls of night-soil; two barrowfuls of fine yellow loam. These composts require two years’ preparation; in the first, they are mixed up in a hole in the earth; and in the next, turned over every month in an open exposed situation, so as every part may be thoroughly frozen in winter, and heated by the sun and penetrated by the air in summer. Those composts, he says, he used with very great success, though they contained no sand. He next introduces that material thus: four barrowfuls of loam, steeped in night-soil and urine; two barrowfuls of goose-dung, mixed with blood; two barrowfuls of sugar-bakers’ scum; and two pecks of sea-sand; or, two barrowfuls of night-soil; one barrowful of cow-dung; one barrowful of fine yellow loam; and one peck of sea-sand: or, two barrowfuls of night-soil; two barrowfuls of goose-dung; two barrowfuls of cow-dung; two barrowfuls of fine yellow loam; and two pecks of sea-sand. Great stress is laid on the blood, which, “when mingled with other manure, does wonders beyond every other quality.” The best sowing times are “stirred and turned, but never manured.” The composts are “rather kill and destroy your plants, than nourish them. Rendered sweet and wholesome, it will be the means of throwing brilliant colors into the pipe or petals, and of giving life and vigor to the plants, as much as fine old port or rich Madeira wine does to the human constitution.” *(Cult. of the Auricula, &c. p. 77.)

6533. The late P. Kenny, Hogg observes, “gardener by profession, was, perhaps, one of the most successful and eminent growers of auriculas in his day, and who won as many prizes as most men, during the course of ten or twelve years that he lived at Tottoridge, in Middlesex. He certainly had all the benefit of the situation, and soil, which, coupled with his fondness for the flower, and his skilful treatment of it, (to say nothing of his being almost constantly in the garden,) gave him a decided superiority over many of his competitors, as it was his custom to change the compost of his old staple loam, of rather a sandy nature; this he sweetened, by frequent turning. His next principal ingredient was sheep-dung and hay-litter, obtained from the sheds used to rear early lambs, well rotted, by being turned, mixed, and fermented in the same manner as the gardener does horse-dung and straw-litter. His third was horse-dung: his third was horse-dung and hay-litter; one tenth coarse sand. These formed his compost for growing them in; but he had another of a richer quality, if I may so term it, with which he used to top-dress his plants, and this he would do sometimes twice in the year. When they killed any sheep, he always reserved the blood, and mixed it with the dung of poultry. These two ingredients, he considered, when he returned them to his compost, constituted sheep-dung, and poultry dressing.” *(Treatise, &c. p. 104.)

6534. The Lancashire growers, Hogg informs us, “use horse-dung and cow-dung indiscriminately, sometimes mixed, sometimes apart; the dung of poultry most frequently; and old decayed willow wood, when they can get it; with the mould cast up by moles; taking care that the same be properly mixed, sweetened, and palaverised. In winter, they throw it up in narrow ridges, and when the top of it is frozen, they take it going to do, and they have no soil of it.” *(Treatise, &c. p. 104.)

6535. Justice gives the culture of the auricula in a “hitherto-unattempted manner, and which, although repugnant to the rules given by our cultivators of auriculas, I shall here insert, as the only true method to procure a fine blow of auriculas, such as I had this last spring, 1793; which, took, to the sight of numbers of species, and was indeed among the best Auriculas ever seen in England. In this, the auricula was composed of the most capital flowers in England and Holland, and some very fine seedlings of my own raising.” The soil he recommends is, one half fresh loam, from under an old pasturage; and one third of the ordinary third-rate plants, viz: two thirds sheep-dung and hay-litter, one tenth coarse sea or river sand: no horse-dung to be used, and the ingredients not to be mixed together till a few days before, when they are mixed for some time, they breed vermin and worms. He adds, “if you use fullers’ earth to them, it must be done in the proportion only of an eighth part, and at no time but either at the time of planting, or when it is used in spring, it must be well dissolved in warm water before being used, and then use no sand.” *(Brit. Gard. Direct. art. Auricula.)

6536. Curta, in a note to the last edition of Maddock’s work, says, “We have seen the strongest auriculas produced from the following ingredients: two thirds of the rotten dung from old hot-beds reduced to fine mould; one third containing equal parts of coarse sand and peat or bog earth, such as is used in the culture of heaths, mixed well together by stirring or screening, and suffered to be well aired by frequent turning of the friezes during the frost’s winter.” *(Florist’s Diary.)

6537. Henderson, of Delvine, uses two parts of very rotten dung from old hot-beds, one part of vegetable mould, one quarter of river sand, mixing the whole, and exposing it for a winter. *(Caled. Hort. Soc. Mem. i, p. 9.)

6538. The compost in most general use among auricula-growers is of fresh loamy soil and perfectly decomposed cow-dung, equal parts of each, adding one tenth of the mixture of sea or river sand. Some use leaf-mould instead of cow-dung. The whole incorporated and prepared for one summer and one winter in the same mould. *(Treatise, &c. p. 104.)

6539. Manner of growing. The common sorts are grown in beds or in mingled borders; but all the fine flowers in pots. Maddock recommends pots of six inches and a half interior diameter at top, seven inches deep, and the interior bottom diameter four inches, for full-grown flowering plants; and smaller sizes for seedlings and newly separated offsets. Emmerton uses pots for large blooming plants, eight inches high, five inches and a half diameter at the top, and four inches and a half at the bottom measure.

6540. Time of potting and transplanting full-grown plants. The most advisable time to pot auriculas, according to Maddocks, is immediately, or soon after the
this should be repeated annually (notwithstanding the opinion of some who say the plants bloom better the second year after potting) for this obvious reason, that it preserves the health and constitution of the plants, by affording them a fresh supply of nutrient; and at the same time the cultivator has an opportunity of curtailing their fibres, if grown very long, or of cutting off the lower part of the main root, if too long, or the end of it, if decayed; thereby forcing the plants, as it were, into a state of action, and causing a continued circulation of their juices, during the summer, in the formation of new fibres for their necessary sustenance and support: whereas, if this operation of potting is not performed till the second year, the soil must have lost a considerable part of its nutritious quality, which will produce a proportionate decline in the strength of the plants: and if it be deferred till the autumn, there will not be time for a sufficient reproduction of the fibres before winter sets in, the effects of which will be a faint-colored and weak bloom the ensuing spring. The only objection of any importance, against spring potting, is that some sorts will in consequence be more inclined to blow in the following autumn, and thereby deprive the plant of its capacity to bloom well the ensuing spring; this, however, occurs but in few instances.

6351. In potting or transplanting auriculas, the plants should be carefully turned out of the former pot, and the earth shaken from its fibres, which should be curtailed if found too long and numerous, together with the lower end of the main root, and the fibres attached to that part, if it appears too long, or somewhat decayed; the plant is to be at the same time carefully examined, and wherever any unsoundness appears, it must be entirely eradicated by means of a sharp penknife, let the extent of it be ever so great, till no appearance of decay remains; particularly in that part of the main root where it enters the surface of the soil, where cold and water act, being always the more subject to decay than any other part, and for the same reason is the most difficult to heal: the wounded part should be immediately exposed to the sun, and when the surface of the wound is perfectly dry, a cement should be applied, consisting of bees' wax and pitch, about one half of each, warmed and softened and run freely in the direction desired; this will prevent hard when cold, it will retain moisture, and is the best application yet discovered, to prevent further progress of the decay. Whenever the lower leaves of the plant, next the surface of the earth, become yellow, or dried up, it is an indication of decay in the plant; On this occasion the size and direction of the surface, and that of the plant is to be selected; it is to have a hollow oyster-shell placed with its convex side upwards, over the hole at the bottom, and then to be about three parts filled with compost, higher in the middle than at the sides; the plant is next to be placed thereon, with its fibres regularly distributed about the edges of the pot, with the bottom and upwards, that is obtained from the compost, adding a little clean coarse sand close round the stem of the plant, on the surface: the bottom of the pot should then be gently struck two or three times against the table, which is supposed to be made use of for the sake of convenience in the operation, in order to render the soil more firm and compact; this will cause it to sink or subside about half an inch below the top of the pot, which will prevent the loss of water when it is administered.

6352. The true depth to plant an auricula is within about half an inch of the bottom of its lowest or outside leaves; as the new and most valuable fibres proceed from this part, so they should immediately measure for, and to strike into, or otherwise they will perish; it will likewise encourage the offsets, if there be any, to strike root sooner than they would do if not in contact with the soil. (Florist's Direct, 132.)

6353. On the foregoing directions, by Maddock, his editor, Curtis, has the following note: "Notwithstanding the author has so particularly recommended the annual fresh potting of auriculas, we must beg leave to differ in opinion from him, as far as relates to those plants which are intended to bloom strong the following spring, the mode of potting advised being to shake the whole of the earth from amongst the fibres, and to examine the latter, and of this severe operation being performed in the spring, when the plants ought to be making their most luxuriant growth, will have evil consequences. The case is simply this: the plant being firmly established, nature intends its greatest growth in the spring; during this rapid growth, the operation gives an unnatural shock to vegetation; the consequence is, that the fibres are deprived of the water and air so essential for supporting the growth necessary to form a strong-blooming plant. Having given our opinion against it, we substitute the following recommendation: select those plants intended for strong blooms the following spring from the younger ones, turn them out with their balls of earth entire, and if the fibres are healthy, return the balls into a set of pots one size larger than they were in before, adding new compost to fill up; we have no objection to remove as much earth as can be done without disturbing the mass of fibres; in this state treat them as usual, and when those which have bloomed strong on this plan are out of bloom, put them on the plan recommended by the author. We beg leave also to notice, that it sometimes happens that the oyster-shell placed at the bottom of the pot by fitting too close confines the water in it, which is inevitable destruction to the plant; we should advise particular care to be taken for the effectual drainage of a superabundance of wet, by putting two or three pieces of broken pot over the surface of the bottom.

6354. Emmerton disapproves both of spring and autumn transplanting, and says, "the best time for the operation is soon after they are out of bloom; say about the 22d or 23d of May;" but he adds—

6355. From the 29th of May to the 15th of June, I have transplanted my flowers with great success, even as late as the 15th of July. On no account remove a general collection a week later, at least, those you intend to bloom very strong; by this means they will have three or four months to get well rooted, and will go more readily to flower, and if you transplant them earlier in the spring, you will cause so near their time of blowing, that the check they will receive by transplanting will prevent their blooming strong. Strong-blowing roots should not be removed more than once in two years; to do it oftener would be to injure the plant; the exhibit on your flower shows that this has been the case, because there is no portion of the plant right, till the roots have reached the sides of the pots, and it seldom or never happens that they get suf- ficiently well established in a full-sized auricula-pot, in one year. By no means remove your large-blooming auricula-plants in dry hot weather, as by shaking the mould clean out of the plant the roots will not form a new ball; they are supposed to be imprisoned and what is most necessary to be done for them is to take care that I am satisfied dry hot weather is an improper time, except they are fine young maiden plants, in small pots, which should be slipped out of the pot with the whole ball of earth, and then immediately planted in a full-sized blooming-pot for the coming season; in this last case I used to pay no attention whatever to the dry weather. If your large-blooming-plants have not been removed for two or three years, their
small roots will have filled the pots, and probably their large, or what is called by some the carrot root, may be grown so long as to require shortening; in this case the plant must be taken out of the pot, and the roots removed from it; before you can see what is necessary, for if you suffer it to remain too long, it will either get rotten at the end, and always keep the plant weak, or will be too long for an ordinary pot; besides, it would want shifting every year, and never produce fine strong flowers. Reduce their small roots to about ten or a dozen, leaving those that are necessary, and you will be able to transplant it upon the nearest plant and plant. in the largest-sized year, for symptoms of worm, are the causes of the long, circulation square in glass, of seventy 6368. 6367. attended the length, of the plants which, by shifting, in rapidlv growing, of two inches in the same, a circumstance, which, they are intended for a cricket-ball, or rather larger, as much depends on the size, and age of your plant. (Treatise, 132.)

6369. Hogg recommends the first week in August, because: "if you put your plants at this early period of August, in which they are to remain, till they flower again next spring, the space of nearly twelve months, the strength of the compost must be greatly reduced before that time, particularly as they require so much water during the hot months of June and July; this must tend, beyond all doubt, to exhaust the nutriment contained in so small a body of earth, as is in the pot; by which means they will, unless by the whole strength of fibre, or to produce strong blooms in the spring. Early potting is attended with another evil consequence; for, the plants being removed into fresh and more vegetative earth, accompanied with daily waters, forces them prematurely into a state of active vegetation, and causes them to flower late in the autumn, a circumstance, which the florist always views with regret, as it in a great measure destroys his hopes of a fine bloom at their natural and expected season, towards the latter end of April: this last argument of itself appears to me quite conclusive in favor of late potting. The slips or offsets will also have acquired more strength and better roots, by being suffered to adhere to themselves until the beginning of August, in protestation of being stained. From the beginning of August to the beginning of November is a period quite long enough for the plants to strike fresh fibres, and to get well established in the pots, before winter; and, with the return of spring, you may expect a vigorous growth of the plant in all its parts. The customary mode is, to shift the young plants from pots, or repot them, every second or third year, according to the state and condition of your plants. The late Kenny let his remain very frequently until the third year, reducing the ball of earth only, trimming the fibres, and examining the carrot or main root. Treating the dorm in a sunny and a moist "air am atmosphere.""

6370. Justice pot suckers, and plants old plants, in August. Henderson, of Delvina, says, "the shifting season is always, with me, about the third week of May, when the plants have done flowering. At that season, I shake the mould from the old plants, and cut the end of the stump up to the first joint of the main roots. (I am not referring to the largest-sized pots for two years.) After dressing the wounds with gum-mastich, to prevent gangrene, the plants are repotted in the second size of pots. Next May they are shifted, with the ball entire, into the largest size, or flowering-pots; so that from the first potting of the young plants in small pots, to a complete growth, and the plants being raised one year in small pots, one in the second size, and two in the largest, or third size. A little river-sand is put round the stems at all the shifting; and if any suckers are made by taking off the suckers, they are dressed with mastich. At all times the stems are cleared of sprouts above ground as they appear, but suckers from under are allowed to grow, in order to form young plants." (Caled. Hort. Soc. iii. 530.)

6388. Removal and potting of offsets. When offsets have formed one or more fibres, an inch in length, Maddock directs to remove them by means of a piece of hard wood, or by the use of the fingers, to be separated from the old plant with safety, and replaced round the sides of a small pot, &c. with as much, with the same compost, till they become sufficiently grown to occupy pots separately: if a small hard-glass be placed over each pot containing these newly-planted offsets, it will cause their fibres to grow more rapidly; but it should not be long continued, as it would have a tendency to draw and weaken the plant. (Maddock's Directory, 139.)

6389. Emmerton says, "You may separate in offset from the mother plant any time between February and August, according as they are in size, or are wanted for increase, and plant them immediately again, by four or five inches from each other, the time of planting moved, or sired, no offsets must be allowed to grow on the old plant, and especially none on the stem without fibres. Rub them all off when they are about the size of hemp-seed." (Treatise on the Auricula, &c. 135.)

6370. General culture. Maddock keeps his auriculas during the winter within a room where there is a summer repository (fig. 604.), and the other in a winter repository. (fig. 604.)

6371. Summer repository. "The following is recommended as a proper plan for the summer repository, viz. in the first place, there should be a bed or coal-ash, or sand, well mixed in the formed in the place where it is intended to be erected, about five or six inches thick; or a platform of plain square tiles, closely fitted to each other, on the surface of the ground, to preserve the pots from the common earth worm, which, by gaining admittance into them, would perforate, and alter the consistency of the soil, in such a manner as to prove very injurious; upon this foundation, the rows of bricks (fig. 604.) are to be placed in straight lines, about two or three inches asunder, which will allow a free circulation of air, or air in the interstices between the pots when placed upon them, an object of great importance, especially, in mild, warm weather, when the air is most inclined to stagnate, and become impregnated with noxious effluvia. The platform, will contain rows of pots from nine to twelve inches above the level of the ashes or platform. There should be two rows of substantial stakes, three feet long, and five inches by three wide, one row of which should stand alone, at about three or four inches distance from the two outside rows of pots (b); these stakes (c) should be driven twenty inches into the ground, with their narrow sides towards the pots, and have notches cut in their tops, to receive the edges of the boards mentioned in the following parts of this plan. (fig. 604.) By way of illustration, suppose the whole length of the platform to be twelve yards, and the width three feet for the thickness of seventy pots; a sufficient number to constitute a moderate collection for a private gentleman. Three shutters (f), made with feather-edged inch-deal boards, each four yards long, and two feet six inches wide; the centre side: three of the notched stakes will be sufficient to support one of these shutters; of course, fifteen stakes at proper distances will completely answer the purpose. On each of the one side: the notches are to be cut in the form of a V, two inches deep and three inches wide at the
AURICULA.

Auricula. When the plants require to be covered with them, in the form of the ridge or roof of a house, well fitted and sloping equally on both sides, so as to throw off rain, without even admitting it to drip through upon the plants in any part. It is necessary that a rail, or row of supports, be fixed at right angles, and proceed up the slope, so that the steps of pots, to support the shutters when closed or opening, especially as it is usually more convenient to begin to cover or uncover on one side first, and finish on the other; without a support of this kind, in such a case, the shutters must fall down upon the plants: a similar exterior rail, or row of stakes, is necessary to support the ground cover of the plants, or carpets of snow, (fig. 604, d), instead of the wooden shutters: these are to act in the same manner, but will admit of light when the plants are of necessity shut up from adverse weather, which so frequently occurs during winter; the admission of light at such times is indispensably necessary to the wellbeing of the plants, especially when a frost occurs, for it renders it impossible to keep the beds of grass and the other winter bedding for a period, perhaps for a day or two, with little or no intermission. In the first favorable weather that occurs in February, it is necessary to divest the plants of their decayed exterior leaves and, by the middle of that month, the operation of earthing up, as it is termed, should commence; that is to say, the number of the pots should be carefully taken away, about an inch deep, and fresh compost with the addition of a little loam, to give it more tenacity, should be substituted in its stead: this will contribute greatly to the strength of the plants, and the vigor of their bloom; at the same time it will afford a favorable opportunity to examine the plants, and, if necessary, to judge whether they require any additional support. In this early season with safety: these offsets, when properly planted in small pots, should be placed in a frame, in some warm sheltered situation, till the roots are established. The auricula is by no means a tender plant, yet it will be proper to cover the repository with mats, in case of severe frost; for although it is generally supposed that the pot-plant has a degree of hardiness far beyond that of the outdoor plants, many of which, when grown in a cool but airy situation, have been exposed to frost with much success. The winter situation of the plants, and the necessity of shelter, call for the attention of the grower, who should keep himself informed of the approach of frost, and endeavor to prevent the dormancy of the auricula, by earthing up the plants and giving them an additional protection against the frost. Some winters are more favorable than others: if the season has now the appearance of open weather, you may treat your plants nearly in the same manner as the two last months; but if you have snow, and the weather is now a severe frost, you must be careful to keep the exposure. A trifle of frost, but no serious danger, in the hardy plants, but the mould should not be allowed to remain long in the pots, as by the end of January the bloom is formed, although very low in the heart of the plant; he therefore covers with mats till the weather becomes mild and open, giving air, however, a few hours in each day, and prevents the plants from becoming too much crowded. If the auricula be under glass, it should be placed in any part of the greenhouse that is sufficiently warm to prevent the plants from being injured by the frost. The auricula is generally placed in sunken beds in a greenhouse, either on the window-sill, or in a vases, &c., against the wall of the house; or it may be planted in the pots, and placed in a plate, &c., in the manner of Maddock; but he procures no covering to exclude the rain. (Treatise on the Auricula, &c. 145.)

 justice sets his plants in a full northern exposure, and without covering, to the 29th of October. Whether of these plants be adopted, the plants must be kept clear of weeds, the soil gently stirred when dry, or mossy, water supplied in dry weather, and the leaves, as they become yellow, drawn off close to the stem.

Winter repository. In the end of September or beginning of October, Maddock removes his auriculas to the winter repository, which is to be constructed in a manner exactly similar to that for the summer repository. For the sake of the observer who should desire to cultivate them, a description of a winter repository (fig. 604, d), instead of the wooden shutters: these: are to act in the same manner, but will admit of light when the plants are of necessity shut up from adverse weather, which so frequently occurs during winter; the admission of light at such times is indispensably necessary to the wellbeing of the plants, especially when a frost occurs, for it renders it impossible to keep the beds of grass and the other winter bedding for a period, perhaps for a day or two, with little or no intermission. In the first favorable weather that occurs in February, it is necessary to divest the plants of their decayed exterior leaves and, by the middle of that month, the operation of earthing up, as it is termed, should commence; that is to say, the number of the pots should be carefully taken away, about an inch deep, and fresh compost with the addition of a little loam, to give it more tenacity, should be substituted in its stead: this will contribute greatly to the strength of the plants, and the vigor of their bloom; at the same time it will afford a favorable opportunity to examine the plants, and, if necessary, to judge whether they require any additional support. In this early season with safety: these offsets, when properly planted in small pots, should be placed in a frame, in some warm sheltered situation, till the roots are established. The auricula is by no means a tender plant, yet it will be proper to cover the repository with mats, in case of severe frost; for although it is generally supposed that the pot-plant has a degree of hardiness far beyond that of the outdoor plants, many of which, when grown in a cool but airy situation, have been exposed to frost with much success. The winter situation of the plants, and the necessity of shelter, call for the attention of the grower, who should keep himself informed of the approach of frost, and endeavor to prevent the dormancy of the auricula, by earthing up the plants and giving them an additional protection against the frost. Some winters are more favorable than others: if the season has now the appearance of open weather, you may treat your plants nearly in the same manner as the two last months; but if you have snow, and the weather is now a severe frost, you must be careful to keep the exposure. A trifle of frost, but no serious danger, in the hardy plants, but the mould should not be allowed to remain long in the pots, as by the end of January the bloom is formed, although very low in the heart of the plant; he therefore covers with mats till the weather becomes mild and open, giving air, however, a few hours in each day, and prevents the plants from becoming too much crowded. If the auricula be under glass, it should be placed in any part of the greenhouse that is sufficiently warm to prevent the plants from being injured by the frost. The auricula is generally placed in sunken beds in a greenhouse, either on the window-sill, or in a vases, &c., against the wall of the house; or it may be planted in the pots, and placed in a plate, &c., in the manner of Maddock; but he procures no covering to exclude the rain. (Treatise on the Auricula, &c. 145.)

677. Hogg places his auriculas in frames in October, the frames are placed on a bed of ashes, and are raised on bricks to admit a free current of air under them; but when the frost sets in, about Christmas,
PRACTICE

6378. The Lancashire growers have no frames or lights, but make use of weather-boarding, with hinges, fixed against some wall or fence, in a south aspect, to prevent them from the rain and snow, resting, when shut close, upon a board nine inches high; but this is not the only exception excepting in very severe weather: they are exposed to the right of the house, or at least a corner of it (Hogg).

6379. Justice places his auriculas in what he calls a bunker or shed, on the 10th of October. This bunker is a stage with boarded ends, front and cover, placed against a wall with a north-eastern exposure. He gives an impression of being as much as possible; by this means he exposes the plants, and if they are weak he adds the proportion of one eighth of fullers' earth to the compost.

6380. Bloom-stage (fig. 605). This, according to Maddock, should have a northern aspect, that the sun may shine upon them; it is to consist of four rows of shelves, in the form of steps, but not must exceed five feet; the front, or lowest shelf, should be two feet five inches from the ground, the second about three inches higher than the first, and the rest of these shelves should be about six inches wide, strong, and well supported, otherwise the weight of the pots will cause them to bend or give way. If the stage consists of such shelves, depth, from front to back, ought to be about two feet eight inches; the north or front elevation of the stage should not be less than seven feet, gradually sloping to about five feet six inches on each side; in which case, if the north covering of the frames of glass. The frames of glass made use of on the south side of the winter repository will answer extremely well for this purpose; but as they will not be wide enough to form the roof completely, without addition of a timbered shed, the glass should be placed on the front part of the slope, and the lower edge of the frames of glass may rest upon them; these boards will answer another good purpose, by preventing the sun, which at this season of the year has obtained a considerable degree of altitude, from shining on the back of the plants, and perhaps being reflected by the mirror of the day, when it has most power; although the plants of the back row will, in consequence, have rather less light, yet it is not so materially injurious as the former. The posts supporting the roof of the stage, on the south side, may be so constructed, and placed at such distances from each other, as that the wooden shutters, made use of on the north side of the stage, may fit between the two frames of glass, and form a kind of window; the remaining space to the ground may be left open in mild calm weather, or may be easily closed up, by a line of mats sewed together, when it is otherwise. The east and west ends of the stage should be entirely boarded up from top to bottom, and the front left open, unless in unfavorable weather, and at no part of the stage may be either sunlight or shade considered; and glass covering of the hyacinths will be a sufficient protection which, with proper care, will prevent rain dripping through in that quarter.

A row of fine polyanthus, in pots, may likewise be introduced in front of the hyacinths, as they likewise blow at the same time; it will add to the variety, and form altogether a more elegant assemblage of beautiful flowers than any other plants at that season of the year. These hyacinths should stand on the last or most distant shelf, and the shortest in front; those stems which are weak and tend should be supported with small wires, fixed in the earth behind them, so as not to be easily dis- cnsered. If any of the stems and blossoms of those in the back row incline forward too much towards the light, they may be easily recovered to an erect position, by turning the pots for a few hours in the morn- ing; but the glass roof will render very little of this trouble necessary: the pots must be regularly watered, two or three times every week, during the bloom. No person can depend on a complete stage of auriculas, who is not provided in autumn or early in the spring with twice as many blowing plants as his stage will contain, because some will eventually prove defective, and fall in one respect or other: and a succession of proper plants in bloom will be required to replace such as, being earlier than the rest or shorter duration, are no longer eligible to remain on the stage, and ought, in consequence, to be taken away from their stead. Part 3.

6381. As auriculas and hyacinths generally blow exactly at the same time, the beauty and elegance of the scene is considerably increased by having a stage of the former, and a bed of the latter, under the same aspect; the intermediate part should be divided into six feet wide, suspended from the front edge of the roof by hinges; they will serve both, when let down, and also by each having two small iron rods, about five feet six inches long, connected with lower edges by staples, that will allow them to move in any direction, and support the glass. The upper end will defend the path in rainy weather, and also like the shade of light when the sun shines, and at the same time defend the spectators from its heat. The inside of the back and ends of the stage, and the shelves likewise, should be painted black, or some very dark color, by way of contrast to the white eyes, &c. of the flowers; and if a large-looking glass be placed at each end of the stage, the effect produced will be very pleasing, by apparently lengthening the stage each way as far as the eye can reach.

6382. When the bloom is declined, the plants are to be removed into their summer repository, where they will soon recover their former strength and vigor, which, notwithstanding the utmost care and vigilance, have been, in some degree, impaired by standing two or three weeks upon the stage.

6383. Apron of auriculas "To the well-bred housewife a few auriculas will last them for about four or five weeks, viz. to use the language of a florist, to prevent them from being set, when all trouble and danger will be completely over. This strict care commences about the 25th or 26th of March, and ends, as I calculate, by the 20th of April, or thereabouts. Around London, many fine plants of the choicest sorts have always been set by the florists, in such manner that all are enabled to the flower fanciers to draw from their plants under glass so many weeks, night and day. Many florists keep their lights continually over their flowers, day as well as night, from the 1st of January till the 1st of May, and only admit a current of air necessary to prevent their plants from being destructed; this is the probable cause of so many split on. This mode of treat- ment, I am convinced, is highly improper; it draws up the flower-stem, and renders it weak and spind- ling, in a state unfit to bear or produce a bold truss. To bloom an auricula in perfection, it does not require to be continually under glass night and day, longer than twenty-four days, or thereabouts; as a critical examination of the first day's bloom of those which I have kept in my window for the month of April: you will find your window pips expanded, or nearly so, and well adapted to be exhibited on the stage at this time." Previously to this period, however, say from the 10th to the 16th of April, he removes them from the frames (which have a south aspect), and places them under glass in a full or north-eastern aspect. Here they remain till the 29th or 30th of April; and are then removed to the stage in a full north aspect.

6384. Hogg keeps the lights over his auriculas, in April, night and day, to preserve their beauty unimpaired. Air he admits by raising the sashes behind; he covers up close at night, "this being the very crisis of
time that requires your most particular care." He thins out the pips or blossoms, leaving not more than thirteen, nor fewer than seven on a truss or umbel. In thinning, "they should be taken out two or three at a time, and it requires some taste, nicety, and art, to perform this operation well, that the blossoms which are left on may grow in a regular equidistant form, so that any common spectator might suppose that no such thinning of the pips had taken place, but that they had grown exactly in that form, and with that number, from the first." Towards the end of the month the flowers are removed to the stage fronting the east.

6385. The Lancashire growers, "in blooming time, set their large show-plants under hand-glasses, in an east aspect, to receive the morning sun only. The plants are, perhaps, not so early in bloom as those wintered in frames, but when their stems are not drawn, and they are able to support the trusses firmly: the millet and rot do not take them so readily as when in closer situations."

6386. Justice blows his flowers in the bunkers, or sheds, exposed to the full north; he gives them all the air he can, but excludes the sun, shelters them from winds, and waters them well twice a-week. (Brit. Gard. Direct. art. Auricula.)

6387. Henderson, of Delvine, blows his flowers in a frame (fig. 606.), which he says, "answers all the purposes of frame, hand-glass, and stage, used by the English florists; at least I make it do so. I have only to erect a screen of matting or poles in front, during the flowering season. The plan of it (a) is a long hexagon, which has a span roof (b) and a low stage sloping on all sides (c). In the elevation are eight ventilators (d), eight hinged sashes (e), and as many iron rods on staples for holding them up (f)." The whole seems a simple, economical, and sufficiently neat structure.

Subsect. 16. Primula, or Primrose Family.—Primula. L. Pentand. Monog. L. and Primulaceae, B. P.

6388. The primrose family, grown as florists' flowers, consists of the polyanthus, primrose, cowslip, and oxlip.

6389. The polyanthus is the Primula vulgaris, var. Polyanthus, L. Primula, French, German, and Italian. In its wild state, the common primrose is too well known to require any description, it produces its flowers on numerous peduncles; but, by cultivation, throws up a scape, bearing an umbel of numerous flowers, brown, purple, red, and yellow. Linnaeus asserts, that the peduncles in the common wild primroses spring from a scape, which being so short as to be concealed among the leaves, has not been observed. Curtis, however, found it in a few plants, and also that wild primroses, introduced into Dr. Buxton's garden, at Maize Hill, near Greenwich, produced flowers both with and without a scape, and became, color excepted, perfect polyanthuses. Many botanists consider, that the polyanthus, primrose, cowslip, and oxlip are one species; and the Rev. W. Herbert seems to have proved it, and the same thing as to Primula auricula, helvetica, nivealis, and viscosa. (Hort. Trans. iv. 19.) It is sufficient for our purpose to observe, that the polyanthus is a very permanent variety, which does not readily return to the primrose, and that it is in high repute as a select and border flower, appearing in March and April, when there are few others to decorate the flower-garden.

6390. Varieties. These are as numerous as the varieties of auricula; and, as in that plant, single flowers are most esteemed.

6391. Criterion of a fine polyanthus. "Its properties are, in most respects, similar to those of a fine auricula, viz, the stem, peduncles, or foot-stalks, and formation of the bunch or truss; therefore, a definition of its pips, or petals (fig. 657. a), only remain necessary to be considered in this place. The tube of the corolla above the calyx, should be short, well filled with the anthers or stamens, and terminate fluted, rather above the eye. The eye-should be round, of a bright clear yellow, and distinct from the ground-color; the proportion as in the auricula throughout the flower. The ground-color is pale apricot, which shaded with a light and dark rich crimson, resembling velvet, with one mark or stripe in the centre of each division of the limb, bold and distinct, from the edging down to the eye, where it should terminate in a fine point. The pips should be large, quite flat, and as round as may be, consistent with their peculiar beautiful figure, which is circular, excepting those small indentures between each division of the limb, which divide it into five or six heart-like segments. The edging should resemble a bright gold lace, bold, clear, and distinct, and so nearly of the same color as the eye and stripes are scarcely to be distinguished; in short, the polyanthus should possess a graceful elegance of form, a richness of coloring, and symmetry of parts, not to be found united in any other flower." (Madock.)

6392. Propagation. By dividing the root, or by slips, for ordinary purposes; and by seed, for obtaining new varieties.

313
6393. By seed. The plants from which seed is to be saved are to be separated from the stems, and treated in the same manner as seed-bearing auriculas. When ripe, it should be cut off with part of the stem, and so preserved till the sowing season, which, as well as the mode of procedure, are, according to Maddock, the same as for the auricula. Emmerton says, flowers intended for seed should be selected on the same principle as he directs for the auricula; and he recommends Pearson's Alexander and Nicholson's Tantarara as excellent flowers to breed from. Knight's mode of castration may be adopted.

6287. "I have great success in raising polyanthuses and primroses from seed." He gathered the seed generally about the 5th of June, and sowed it ten days afterwards in boxes, placed in the open air, under a wall or hedge with a north aspect. In July, he directs to "prepare a nursery-bed of the same earth in which they were sown, and plant them carefully out, taking up as much earth about their roots as you can, so as not to disturb their young fibres, planting them twelve inches asunder, and shading them from all sun as they have struck new roots; keep them clear from weeds, and give them gentle waterings, and let this nursery-bed be made in such a situation as to have the morning sun only. Some plants will show their flowers in the autumn, and many of them in the spring following. Select the best, and plant them in a bed by themselves in a shady moist situation. In November, top-dress the plants, which will greatly strengthen them for the succeeding spring. They require to be transplanted every two years." (Brit. Gard. Direct. 218.)

6396. Hogg says, "the primrose and polyanthus require a much greater portion of sandy loam than the auricula, a very small quantity of rotten dung, and a little leaf-mould or heath or peat mixt, mixed with: in this they are found to grow extremely well." 6287. Manner of growing. Maddock says, they may be grown in the same sized pots as the auricula, and be treated in the same manner; but as they are more impatient of heat and drought, and partial to shade and moisture, they may, with equal propriety, be planted on cool and shady beds or borders. This is the general practice of almost all the growers of this flower.

6287. General culture. The plants are very hardy, and seldom perish in the coldest and wettest seasons; but, during the heats of summer, they are frequently destroyed by snails and slugs, and by a small red spider. "This insect," Maddock observes, "often attacks such plants as are in a state of vigor, or with the old and worn; it commences its depredations in the early part of summer, and continues them as the heat and dryness of the weather favor its existence: the juices also of the plants being then more viscous and saccharine, afford it more suitable nourishment than at any other season. Such plants as appear infected should be immediately selected from the rest, taken out of the earth, and soaked for two or three hours in a strong infusion of tobacco-water, and be replanted in a fresh soil or compost, and removed to another situation remote from the former. If the whole bed or border of polyanthuses is overrun with this insect, it is best to take up all the plants, serve them in the same manner, and plant them elsewhere. The bed or border from whence the plants have been taken, should be immediately dug up or trenched, and suffered to remain fallow till the following season, or be occupied with some crop not liable to the same calamity." (Florists' Directory, 228.)

6399. The primrose (P. vulgaris, L. (Eng. Bot. 4.) Primener, Fr.; Shawhose Primule, Ger.; and Primacen, Inal.) (fig. 607.) has a perennual root, appearing as if bit off at the end, with a singular smell like that of the anise. It is a native of most parts of Europe, in woods, coppices, and sheltered lanes, particularly in a clayey soil. The flowers of the wild plant are almost always of a bristowe-color, but sometimes of a purple hue; they appear in March and April.

6400. Varieties. The double varieties produced by culture are in most esteem, of which there are —

6401. The cowslip (P. veris, L. (Eng. Bot. 5.) Primel, Fr. and Schlusselbaume, Ger.) (fig. 608.) is distinguished from the primrose, by smelling more strongly of anise, by shorter leaves, and by an umbel with a leafy involucrum. It is a native plant, and found in moist pastures, in open situations, flowering in May.

6402. Varieties. Both double and single varieties are in esteem; but the plant has not been so much cultivated as the primrose. Gibbs, nurseryman, who has raised a great many very handsome varieties, says, he separated the seed, differing in color, magnitude of the umbel, and in some being double, and in the hose-in-hose form. "May 10th, 1818, Gibbs sent a large collection of flowers of varieties of the common plant, to his garden at Brompton. He raised them from the seed of plants, originally derived from the wild cowslip, which had sported into varieties, and by frequent reproduction had attained their present excellence. The changes that have taken place in magnitude, in the size and the interval of the tressises, and in the size of the flowers; the selection appearing to have been from the darker hues, though some paler flowers were in the collection. However great the variation was in the points alluded to, yet none of the specimens appeared to have lost the peculiar character and appearance of cowslip or common hose-in-hose, and some of them have become what florists term hose-in-hose, which appears to be the conversion, more or less, of the calyx, into the appearance of the corolla." 6403. The oxlip (Pedalium, L. (Eng. Bot. 518.) Pavillon, Fr. and Gardnemprincl, Ger.) (fig. 609) is distinguished from the primrose by its many-flowered scape,
and from the cowslip, by the flat border of the corolla. It is found in woods, thickets, hedges, and sometimes in pastures; but is by no means so common as the primrose and cowslip. It flowers in April and May. Sir J. E. Smith is inclined to think that the oxlip is a hybrid production from a primrose, impregnated by a cowslip; its habit, the contraction towards the middle of the leaf, and the umbellate flower-stalk, indicating the father, whilst in the corolla, its form, color, and scent, it most resembles the mother. (Eng. Bot. 513.)

6404. Varieties. There are a few; but the plant has not been much cultivated with a view to that object.

6405. The propagation and culture of these three species is the same as for the polyanthus:

6406. The carnation is little known in its wild state, though it has been found in England on rocks and walls. It was unknown to the ancients in its cultivated state; but has been a favorite flower in Europe for an unknown length of time. It is generally supposed to have been introduced from Germany or Italy, in which countries it is more cultivated than in England; Gerrard, in 1597, received it from Poland.

"Of all the flowers that adorn the garden," Hogg observes, "whether they charm the eye by their beauty, or regale the sense of smelling by their fragrance, the carnation may be justly said to hold the first rank. The stateliness of its growth, the brilliancy and diversity of its colors, and the sweetness of its perfume, never fail to attract our regard and admiration. The tulip, though styled the queen of the garden, cannot boast of more admirers: they may with propriety be considered the two master-pieces of nature; and, though rival beauties, may be said to share the sovereignty of the garden equally between them. Yet it must be admitted, that the carnation, independent of its fragrance, has this advantage over its rival, that it continues longer in bloom; and that when planted in pots, it can be removed to decorate the green-house, the conservatory, or the drawing-room."

6407. Varieties. Parkinson (in 1629) has forty-nine sorts, which he divides into carnations, or "the greatest sorts in leaf and flower," and gillyflowers, or such as are smaller in both respects. One Tugggey, in Westminster, was the most remarkable man at that time for the culture of these flowers. Rea (in 1702) has 380 good sorts of carnations, which may be increased by the catalogues of modern English florists. The varieties of this flower are now arranged in three classes: flakes, bizarres, and picotees. Flakes have two colors only, and their stripes large, going quite through the leaves; Bizarres (Fr. odd. irreg.) are variegated in irregular spots and with not less than three colors; Picotees (Fr. picquettés, pricked or spotted) have a white ground, spotted or pounced with scarlet, red, purple, or other colors. Of each class there are numerous varieties, arranged under the farther subdivisions of scarlet flake, pink flake, purple flake, yellow flake, &c. scarlet bizarre, crimson bizarre, &c. and purple picotee, yellow picotee, &c. Hogg gives a catalogue of nearly 350 sorts, so arranged, named after great personages, all of which were in his possession at the time he published his Treatise on the Carnation, in 1820. Only double varieties are in esteem. As an oddity may be mentioned the double dwarf carnation of Lige, with sessile flowers.

6408. Description of a fine double carnation. (fig. 610, c and d) "The stem should be strong, tall, and straight; not less than thirty or more than forty-five inches high; the foot-stalks, supporting the flowers, should be strong, elastic, and of a proportionate length. The flower, or corolla, should be at least three inches in diameter, consisting of a great number of large well-formed petals; but neither so many as to give it too full and crowded an appearance, nor so few as to make it appear too thin and empty. The petals should be long, broad, and substantial, particularly those of the lower or outer circle, commonly called the guard-leaves; these should rise perpendicularly, about half an inch above the calyx, and then turn off gracefully, in a horizontal direction, supporting the interior petals, and altogether forming a convex, and nearly hemispherical corolla. The interior petals should rather decrease in size, as they approach the centre of the flower, which should be well filled with them. The petals should be regularly disposed alike on every side, imbricating each other in such a manner as that both their respective and united beauties may capricrate the eye at the same instant: they should be nearly flat, however a small degree of concavity, or inflexion, at the lamina, or broad end, is allowable; but their edges should be perfectly entire, that is to say, free from notch, fringe, or indenture. The calyx should be at least one inch in length, terminating with broad points, sufficiently strong to hold the narrow bases of the petals, in a close and circular border. Whatever colors the flower may be possessed of, they should be perfectly distinct, and disposed in long regular stripes, broadest at the edge of the lamina, and gradually becoming narrower as they approach the unguis, or base of the petal, there terminating in a fine point. Each petal should have a due proportion of white, i.e. one half, or nearly so, which should be perfectly clear, and free from spots. Bizarres, or such as contain two colors upon a white ground, are esteemed rather preferable to flakes, which have but one, especially when their colors are remarkably rich, and very regularly distributed. Scarlet, purple, and pink, are the three colors most predominant in the carnation; the two first are seldom to be met with in the same flower, but the last two are very frequent. When the scar-
PRACTICE after disposed their are approved quest. well let to than by The care then in spect where out at a danger be one thousand pipes, by one thousand boards, (Florist's 6414. 6411.)

The necessary management they were, and adhered to as their side, thousand; quarters. (fig. Directory, 21st.)接收 some kind, as those to when the flowers, as fitting to pink and scarlet, it that is peculiar, medium between pink and scarlet, that it can scarcely be defined to which class they belong. In addition to the foregoing varieties, there is a sort held in great estimation by cultivators, named peacock (fig. 661.) which are very beautiful, and being harder than the other sorts, are in considerable request. The colors are principally yellow, and white spotted; there are others, the kind, as except, that the edges of the petals are serrated or jagged, and the color is disposed in spots, where the others are striped. It is propagated in the same manner as the others. Propagation. By layers and pipings for continuing approved sorts, and by seed for procuring new varieties.

By layers. The time for performing this operation is when the plants in full; some do it till the flowers are on the decline; but in that case the new plants are not so well rooted as those in full, and consequently less able to stand the winter. Laying, by the wounds it infects, considerably impairs the bloom, and generally kills the parent plant. The practical part of the operation has nothing extraordinary in it; a sufficient quantity of pegs (fig. 612. a) and of compost being provided, the pot containing the plant to be laid is placed on a table, and the layers prepared by cutting the leaves (fig. 612. b) then taking out the pot filled up with "light rich mould, not of too fine a grain." (Maddock.) The incision is made by entering a quarter of an inch below the surface, and passing the knife up through the centre of it; it is then to be pegged down, and buried not more than a quarter of an inch below. "It is my opinion," says Maddock, "to peg down the layers in a dry state, being then less brittle, and consequently not so liable to break off as when they are wet and succulent; therefore, as soon as the layers are dressed, the pot should be placed full in the sun for half an hour, in order to render them more flaccid and plant than they otherwise would be. When the layers are properly rooted, they are about three weeks or a month after laying, provided due care be taken to keep them regularly moist, and to shade them from the heat of the meridian sun, they are then to be cut off from the old plant, with about half an inch of the stalk which connects them with it, and be immediately planted in small pots, three or four plants in each, placed round the sides. The pots are to be placed under an arbour, where they are to be covered with mats, in case of excessive rains, till the severity of the weather renders it necessary to remove them into their winter repository, which is to be constructed in the same manner, and have the same aspect, as that described for auriculas."

Hogg commences laying when the flowers are sufficiently expanded to show which is in color, or true to their kind, and which not: this he finds to be about the 21st of July, and he continues laying from that time to the 21st of August. The plants receive a good watering the day previous to laying, because they can not take it for seven days through the rose of the watering pot, or account of preserving the earth on the layer shoots. In performing the operation, he cuts off the nib or extreme point of the tongue, or talus, immediately below the joint, because, "it left on, it is apt to decay," and prevent the protrusion of that granulous matter from which the fibres proceed. Under favourable circumstances they should be laid off in seven days, and they then be planted two or three in a small pot (No. 48.), three inches in diameter, by four inches deep. The pots are to be set on tiles, slates, or boards, there to remain till the middle or end of October, when they are to be removed to their winter quarters. 56.

By pipings. This mode of propagating the carnation is very precarious. Maddock says, "five thousand plants were piped one season, of which not more than one hundred perished; whereas more than two thousand were lost of the same number the year following, with but very little variation in the manner of laying, some of the pipings being laid, and much that was not laid, for which it requires attention and experience to distinguish such sorts from the rest." Piping, however, is often a necessary resource where the shoots are too short for laying, or where in laying, shoots are broken by accident.

The first thing is to provide a slight hot-bed, and cover it four or five inches thick with fine light mould, laid very regular and even. The cuttings intended to be piped are to have two complete joints, that is to say, they are to be cut off horizontally close under the second joint: the extremities or points of the joint are to be slightly shortened, as for laying, which will leave the whole length of the piping from one inch and a half to two inches, according to its strength (fig. 612. c): as soon as thus prepared, it may be thrown into a basin of soft water for a few minutes, to plump it up. The earth on the bed where the pipings are to be placed should be moderately moistened, and rendered rather compact than otherwise; then take a small hand-glass, and with it make an impression neatly on the surface of the soil, in order to know where to stick in the pipings, so as to lose no room, or endanger their being disturbed when the glass is placed over them. The pipings are then to be taken out of the basin singly, and forced into the earth, in their wet state, with a steady hand; but not more than half inch deep. When a sufficient number for the glass are thus placed regular, at equal distances from each other, and rather more than an inch within the mark described by the glass, on every side, they are to be very gently watered, in order that the earth may adhere more closely to them, and thereby keep away the air; after this watering, they are to remain open, but not exposed to a hot sun, till their leaves become perfectly dry, after which the glass is to be placed over them carefully, on the mark that was made by it upon the surface of the soil, before the pipings were placed there. The bottom edges of the glass are to be forced a little into the earth, to prevent the admission of too much air, which so far finish the operation. What further remains to be done is to attend diligently to their management, with respect to sun and air, &c.

The soil ought to be kept regularly moist, till they have formed their fibres; but too much moisture is as prejudicial as too little, and whenever they are watered, the glasses are never to be replaced over them till their leaves...
are perfectly dry. The pippins should have a little of the morning sun, but must be shaded from it when the heat becomes considerable; this will be easily effected by placing mats upon a slight frame of wood, and leaning the tree from the wind. The fruit will then be two hours in the sun.

CARNATION.

4615. The glasses should be occasionally taken off to admit fresh air; if this material point is neglected, the consequence will be a green mossy appearance on the surface of the earth, and an universal mouldiness amongst the plants, which will destroy them, without any knowledge of the cause. Even the moisture retained along the pippin-sticks, while the root, or for almost any other part of the main plant, on this single point, in great measure, depends the good or ill success of the whole undertaking. It, or perhaps entirely, impossible to lay down any rules that will not be liable, as circumstances may, be departed from; planters, therefore, are advised to judge in the art of piping, which must depend on the attention and prudence of the cultivator; there is no great danger to be apprehended from taking off the glasses for a few minutes, or half an hour, when it is cloudy, and the air rather warm and moist; but if no opportunities of this kind occur in due time, it should be done early in the morning; and rather than to omit doing it, the planters are advised to do it, if only for the sake of observation. If, in their judgment, the glasses are kept on the path, in order to air them, and replacing them again over the plants; even this will be of great service, though not equal to a more effectual airing at favorable times, which, indeed, becomes more frequently necessary in proportion to the length of time the pippins have been upon the bed; but when once they are upon the bed, and become more or less, very weak, it will be only a question of time and space, to, viz. agreeably to the following directions: when their fibres are formed, which the additional verdure and growth of the plants will demonstrate, the glasses should be placed over them very lightly, in order that more air may be admitted; and when they become tolerably well rooted, the glasses should, more necessary, be entirely taken away; but it seldom happens that all the plants, under the same glass, strike root together: some are generally a few days or a week fartherward than the rest, as will be apparent by their superior growth and verdure; such ought to be carefully taken up and planted in small pots, for winter preservation, or they may be planted in the sides of large carnation-pots, filled with the compost, where they will soon make rapid progress; the remaining plants which are not sufficiently rooted for removal, must be continued under the glasses, as before directed, till they become so.

4616. Care of pippins as to run or degenerated flowers. It is necessary to be very careful to mark such pippins, whether they run, and whether the plant is (degenerated) or not; because it very seldom happens that the pippins or layers, taken from a run flower, produce any better plants than those that are run or plain-colored blossoms; in consequence of which they are not worth the trouble of propagation; the pippins ought therefore to be excluded. It is, however, accurately known from what plants and in what order that if any of the original flowers were taken from the run color, and the increase of such may be distinguished from the rest, and destroyed. The layers and pippins of the most beautifully variegated flowers will frequently produce run blossoms; but it is impossible to prevent it, especially if the pippins be high-cultivated, and it is impossible to re-form them.

4617. Some people pipe their carnations at the third joint, but it is better to do it at the second; because, in the first instance, the third joint being more hard and woody, the pippins do not strike root so soon, or form afterwards such handsome plants, as when they are piped at the second joint from the extremity of the stock. (Figs. Direct. 398.)

4618. Hogg considers, that piping the carnation should commence sooner than laying, before the shoots get hard and woody; he begins about the first of July. Plants raised from pippins, he considers as sounder, and more likely to encounter the rigors of a sharp winter than layers; but still as laying is the surest mode, he planters generally prefer the one or the other, high shoots, or starchy shoots when very large and easy. He plants them on a bed of dry blood of earth, in a compost of one third maiden earth, one third clay-mould, one third rotten horse-dung, and one sixth sand, finely sifted, that the cuttings, when stuck, may enter easily and without difficulty; the pippins or budding-knife, at the second or third joint, according to the condition of the shoot; but the shorter the joint, the better; the cut must take place horizontally, close below the joint, and the sheath, or part that covers the joint, must be carefully removed and peeled off. When the pippins are cut, the surface of the bed made flat and level, and gently watered through a dry stage, they may be planted in three quarters of an inch, filled with the compost, not too near together. Then let them be watered again, which will help to fix the earth close round them; the glasses on no account are to be shut down close till they are dry, or they will inevitably fog, rot, and perish. The best glasses for piping are those made of the common window-glass, eight inches square and six inches long. Each layer will take four or five glasses, and it is to be remembered that if any glasses are in common use, which are blown for the purpose, too often contain such a thick body of glass as to concentrate the sun's rays, and scorch the pippins. They require shading only when the sun is out, and then with a net or old mat, to admit the glimmering of his rays. If the weather continues dry and hot, they will have a very apathetic growth, early in the season, and much sooner, when the weather is not so dry, one fortnight at least, need not be removed if they are doing well. After, you may take them off from time to time as you see occasion, for half an hour or so in a morning, to give fresh air, and dry the glasses; and if the sky be clear, they should be laid flat at night, pull them in the morning, pull them till they are sufficiently rooted to be transplanted into small pots or a prepared bed, over which it would be advisable to place a frame and lights for a week or ten days, till they take root again. There they may be allowed to remain till the middle or so of September. In taking them up, if you find any not rooted, but sound, and that the buds cannot be detached, do not let them upon the flower, as it is advisable to remove the unripe shoots from the sticks, that the open end of the calyx may incline a little downwards, the more effectually to
preserve it in a dry state, the stones should not be suffered to hang so loose as to be in danger of breaking off with every puff of wind. The seeds ripen from the end of August to the beginning of October: the pericarpium becomes brown, dry, and hard, and the seed, when ripe, is of a black or very dark brown color; those who are not sufficiently attentive to the ripening of their seed are apt to gather it too soon, before it is perfectly matured, in consequence of which the greatest part proves small, pale-colored, and unproductive. In the autumn, it is ascertained in a dry climate in the middle of May; it is then to be sown in pots filled with the compost, and have a little fine mould sifted upon it, barely sufficient to cover the seed: at this season of the year artificial heat is not required, the pot is to be set in a sunny place, and kept moderately moist, but never very wet. As soon as the young plants appear with six leaves, and become about three inches high, they should be planted out on a bed of good rich garden-mould, at about ten or twelve inches asunder, and be defended from excess of rain and severe frosts, by mats on hoops, placed over the plants. We may here point out, in general, the following maxim, advanced an opinion, that the seed of run plants produces as great a proportion of variegated flowers as others; but that the validity of this assertion has not yet been sufficiently demonstrated by experiment."

---

"Hogg's directions differ in nothing of importance from those of Maddock. He says it often happens, that out of 200 blooming plants you will not be able to get even two pods of perfect seed. More was saved in the dry summer of 1838 than in any seven preceding years. Seedlings require two years to bloom, and the chance of getting a good new flower he reckons as one to 100. If a florist raises six new carriages in his lifetime, he is to be considered fortunate. Seed out of the same pod, he says, is reputed to produce flowers of all the different varieties, flakes, bizarres, &c. Emmerton experienced that seed from a scarlet flower will produce a scarlet bizarre, and a rose or pink flake.

The compost for the above purposes is as follows: six or eight rotten horse-dung, one year old, or that has been used as a hot-bed for cucumbers, melons, &c.; one third fresh sound loamy earth; one sixth coarse sea or river sand. These ingredients are to be mixed together in autumn, laid in a heap about two feet thick, in an open exposure, and turned three or four times during winter; or, otherwise, the whole heap may be turned over at the time, and may be the same. In order to rot more perfectly; and, as its surface freezes in winter, it should be pored off, and laid on one side, till the whole mass has been thoroughly frozen throughout; this may be repeated as often as the season permits, and it will be completely fit for use the following spring: the earth and sand may be added or mixed into the compost, and the whole passed through a sieve, mixed and incorporated together, and passed through a coarse screen or sieve, to reduce its parts to take out stones, or any other extraneous substance which it may contain. In country places, where the air is better, it is twice as productive of bloom as if placed in the open ground, in the proportion of which, for such situations, it may be reversed, the half loamy earth and one third dung, with the sand as before specified: the preparation of the compost, in other respects, is to be exactly the same in all situations."

( Florist's Direct.)

Florists' "three barrows: a, one and a half ditto of garden-mould, ten ditto of horse-dung, one ditto of coarse sand; let these be mixed and thrown together in a heap or ridge, and turned two or three times in the winter, particularly in frosty weather, that it may be well incorporated. On dry mornings towards the end of November, I take a barrow of fresh lime, which, as soon as it is slack, I strew over the heap, turning the whole well together; this acts rather to lighten the soil, and destroys the grubs, worms, and slugs. Lime is too well known as a manure to say anything further in its praise here. If there has been much rain during the winter, so that the strength of the compost is reduced, and the salts washed from it, I take about seven pounds of damaged salt and add it to the compost; the compost, thus treated, will supply the plant with an ample supply of mixed or incorporated together, and passed through a coarse screen or sieve, to reduce its parts to take out stones, or any other extraneous substance which it may contain. In country places, where the air is better, it is twice as productive of bloom as if placed in the open ground, in the proportion of which, for such situations, it may be reversed, the half loamy earth and one third dung, with the sand as before specified: the preparation of the compost, in other respects, is to be exactly the same in all situations."

( Florist's Direct.)

Maddock uses pots for flowering plants, "at least twelve inches wide at the top, six and a half inches wide at the inside, and at the bottom, of about an inch in diameter; also three or four smaller holes round the sides of the pot, close to the bottom, to prevent the possibility of water lodging or remaining in that part." Hogg uses pots of twelve or sixteen to the cast, being smaller than those recommended by Maddock.

The operation of potting, according to Maddock, "should commence about the middle of March, if the weather is not extremely unfavorable; but it should not, on any account, be deferred later than the end of that month. The pot is, in the first place, to be half filled with compost, having its hollow side downwards, placed over the hole in the centre of the bottom: this compost is then to be well moistened, and poured into the pot, and the plant is to be set in the middle of the pot, the root end of the plant uppermost. If the plants have been wintered in small pots, containing four plants each, are to be carefully turned out of their pots, with all the earth adhering to them, in a ball; and after rubbing off about half an inch of the surface of the earth, the earth is gently pressed in, so as to fill the spaces between the points of their leaves, the ball is to be carefully placed in the centre of the pot, and the space between it and the sides filled up with the prepared compost. It is very necessary to be attentive in placing the plants, that they be neither planted deeper nor shallower than they were before; the compost should therefore be filled up quite to the rim of the pot, and the earth well rubbed in with the fingers, i.e. half an inch higher than the ball of old earth and fibres: and the whole surface of the earth in the pot, when the operation is finished, should be nearly level or flat; but by no means higher at the centre than at the sides, because the plants would thereby be kept too dry; nor should the compost come nearer than half an inch to the rim of the pot, after it is filled, so as to allow of a little air for the plant to respire and ground on finishing, as an inconvenience will attend its being too full, when the operation of laying comes to be performed, which requires some additional mould on the surface, for the layers to strike into."

Rigg considers the first week in April the safest and best time to pot carnations, and he performs the operation in the same month as Maddock.

General culture. When the plants are potted off for bloom, the pots should be placed in an open airy part of the garden, under an arch of hoops, that in case of cold drying winds, heavy rains, or frozen nights, mats may then be thrown over them to preserve them from the cerebral apathy of the colder weather; in this situation they are to remain, always open to the air, except in the cases above mentioned, and be kept regularly watered with soft water from a fine-rosed watering-pot.
When their flower-stems are grown eight or ten inches high, it will be necessary to support them with a stake, or some other form of support. If the pots, too, are very large, and the small pieces of bass mat: these sticks should be as high as the hoops will admit, in order that the pots may remain under them as long as possible; but when the stems are grown too high for this situation, the pots are to be removed to the stage, and remain there till the time of bloom; the small sticks should be replaced by hoops, and these should remain in their places till after the plants are removed to the bed. Gradually introduce the hoops in the early part of the season; and examine the plants for this purpose every three or four days, as the stems are rather brittle, and liable to be broken by the wind, if not supported in this manner.

If any small, green, winged insects appear on the stems or foliage of the plants, particularly upon or under the leaves, they are generally extinguished or destroyed, either by the means of a small soft brush or feather, by the application of a strong infusion of tobacco-water, or some similar easy and safe expedient; even Scotch snuff dusted upon the affected parts early in the morning, while the plants are covered with dew, will sometimes effectually prevent this mischief.

The calys of many sorts contains a great number of petals, which, as they increase in bulk, will distend and burst it, if not timely prevented: this generally happens a few days previous to the opening time for the blossoms opening, and will, if neglected, soon manifest the effects of such neglect, by letting out the petals on one side, and thereby producing a loose irregular appearance, totally destroying the compact, graceful, circular form which a perfect flower ought to possess, and which is one of its greatest ornaments; but this disagreeable effect may be easily avoided, by fastening a small narrow slip of bladder round the middle of the pod, where it is most swell, and appears to have the greatest inclination to burst. The slip of bladder should be rather longer than is required to go once round, so that one end of it may lay over the other a little, which, by the application of a little gum-water, will adhere firmly together, and answer the purpose completely. Small slips of wet bass mat may be substituted for those of bladder, and are fixed with a single knot round the same part of the pod, will answer nearly as well (fig. 612.)

If the hoop is round, such as is here represented, both from water or rain, by means of strong caps or paper covers (fig. 612. d), about twelve inches in diameter, painted white or green, and formed like an umbrella, to throw off rain; each should have a square tin tube on the summit, and be so fixed that it may be as far as is convenient; the tube should be about two inches long, and have a small hole bored through one of its sides, that it may be fixed by a nail to any part of the stick where required. But when the major part are in bloom, a cloth awning should be placed over the whole, and be drawn up and let down by means of lines and pulleys, exactly as is done in the cases, as for part of the hyacinth, tulip, and ranunculus. The same frame that was used for the hyacinth (fig. 591.) will, without being removed or taken down, answer in every respect for carnations: nor can any other more suitable be contrived or adopted.

In order that the flowers may appear to the greatest advantage, it is necessary that the pots should stand in a circular place, when it is intended that twelve or more varieties shall be cultivated on the same stage should be very strongly supported, in order to sustain the immense weight of the pots, without danger of giving way; the supports of this platform should stand in shallow leaden or earthen vessels, filled with water, to prevent the access of earcivs, which are destructive enemies to the blossoms of carnations, and which are in great number in the light in the interior (figs. 613., 614.) The plants must be protected by the depredations, by biting off and devouring the lower ends or claws of the petals, which of course will cause them to drop out, and thereby disfigure the flower.

There are necessary, but long enough to allow an intermediate space of water, three or four inches wide, between their sides and the supports placed in the centre of each. Earwigs will nevertheless be frequently found amongst the flowers, having been brought upon the stage, where they remain concealed, or dormant, till the flowers are in bloom; or perhaps they may have got in by getting through a small hole, and from thence laid eggs, or may have flown in, as they are evidently provided with wings, though it does not appear that they often make use of them. At all events, it is necessary frequently to examine the plants, and the sticks which support the stems, as earwigs will oft been found concealed there in the daytime, particularly where a flower is about to be shed; and the sticks are secure from the attacks of the earwigs, if the petals hang loose, or drop out, it is a certain sign that an earwig is, or has been there: in the first case, blowing forcibly with the mouth, into the blossom, two or three times, will cause it to creep out; but if it has quitted the blossom previous to the discovery, it should be carefully sought after and destroyed, or it will be impossible to get it again afterwards; if it will not come near the plant, somewhere about the same pot, but not farther distant than the next, or next but one, unless the search has been deferred too long.

If the wires should be suspended from the sticks by small pieces of fine elastic brass wire (fig. 612. e), of unequal length, (sold in the pin-shops,) to support them in an easy graceful manner, neither too near together nor remote from each other: one end of the wire should be introduced into the stick by means of a small awl, and there be fixed sufficiently tight to prevent its dropping out by the weight of the blossom, the other end being fixed to the roots of a small plant, or a petiole, by means of a thin brass or copper wire, to be just large as for four or five; but the latter have much the best appearance in bloom, producing a greater number of blossoms: it is not however advisable to permit every pot to blow, especially of such sorts as are naturally possessed of but few petals; because it would render each blossom smaller and thinner than of itself, and besides, in many of these cases, producing in the same cases, small petals, too, which are not sufficiently supported by the wires, too, which are not sufficiently supported. Instead of these, a few petals, although they are larger, will be found advisable, especially of such sorts as have many.

Carnations are to be treated, during winter, much like auriculas: with respect to the weather, they require the same treatment as auriculas, but with one difference: the plants are to be kept in a dry, light situation, or the greater part, although, in general, three or four pots are as many as ought to be suffered to blow on one plant. These rules, or directions, apply for some few exceptions, but the instances seldom occur.

Carnations are to be treated, during winter, much like auriculas: with respect to the weather, they require the same treatment as auriculas, but with one difference: the plants are to be kept in a dry, light situation, or the greater part, although, in general, three or four pots are as many as ought to be suffered to blow on one plant. These rules, or directions, apply for some few exceptions, but the instances seldom occur.
that state, very liable to contract a destructive mildew, if they have not the benefit of a free circulation of air; the mildew makes its first appearance in purple spots on the foliage, which can only be cured or prevents from spreading, and the best means thus is to give the plants a good pot, as soon as discovered, it being not improbable but that the distemper is, in great measure, owing to a very minute insect, brought into existence by the warmth gathered at such times. Plants thus infected have been from time to time condemned to be burnt to prevent the contagion to others which stand near them, therefore no time should be lost in cutting off the spotted leaves or removing the plants to a distant part of the garden. A repository, constructed in the manner already described, is less liable to the above effects than any close frame or situation can possibly be, because it has the advantage of a free circulation of air at all times, and, being closed, it cannot be burnt, unless it be well covered with mats, &c. as in cases of severe frost; but at such times no such consequences are to be dreaded.

6437. The rains of autumn and winter are generally more than sufficient for carnations, as well as for auriculae, from an excess of which it is proper to defend them; of the two extremes, it is safer to keep them from the excessive rain than from too warm, especially when the moisture is always to be preferred, except when the weather is severely frosty. As too long a deprivation of light is at all times prejudicial to plants, therefore, whenever the winter repository is required to be closed, the poor mats, for the present season, may, of course, be removed; but it should not be lost during the middle of the day, if the sun shines, to take off the mats in front of the glasses, in order to admit its light and warmth. Whenever the surface of the earth in the pots becomes green with moss, or too compact and adhesive, it will be proper to stir it up carefully, about half an inch deep, and thoroughly mix it. Should it be required to perform this upon it: this will prevent any great degree of tenacity in future, and be of great service; it may be repeated as often as required.

6438. In spring, the pots will probably require to be frequently watered, and by the middle of March the operation of potting is to commence, as already described. The blossoms of carnations, particularly the high-coloured sorts, are very liable to be injured when planted, and even when potted, they are then esteemed of little or no value; but when they have only partially run, they may sometimes be recovered to their former state, by being planted in a poor dry soil, that will but just afford sufficient nourishment for their existence (see p. 169). Plogg.

6439. Hogg having potted his blooming plants, supports them with green sticks, in the manner of Maddock, and top-dresses about the middle of June with about half an inch of rotten horse-dung passed through a sieve, which he finds materially to assist the plants, and promote the growth of the layers, on which the rich manures of night-soil, sugar-baker's scum, &c., but, in my opinion, that is not necessary for carnations, and is attended with danger: for, if they are not reduced to a perfect mould, they will corrode, and burn the plants. He waters freely while the pods are swelling, and during the whole time they continue in blossom. As the side shoots are formed, he plants another collars, in order to support it. These collars are made of white card-paper, in the form of a circle of three or four inches in diameter (fig. 612, g), with a hole in the centre just large enough to admit the calyx or pod, without much compressing, and with a cut extending from the centre to the outside or circumference, like the radius of a circle. On these cards the flowers are pressed in shape and form a long time; as these the petals are also finely disposed, and the beauty of the cardanony displayed to great advantage. We must confess, these collars a dear a great expense, and much prefer a tie of thread or bass mat, or tie of bladder reckoned at 8c. to the pound. What we have said in the Bramhall's as low as thirty thousand, and in the autumn or winter, till about nine or ten o'clock, according to the intense heat of its rays; the same in the evening, with as much open exposure to the air at all times as you can give them, without injury to the bloom." In winter Hogg preserves them in frames, in the same manner as he recommends for auriculae. When he has money enough to blow in the pots, he transplants them into buckets, protecting them from severe frosts and heavy rains, and in other respects treating them in the same manner as if in pots. (Treatise, &c.)

6440. The pink is considered by many to be a subspecies of the *D. caryophyllus*; and by others to have proceeded from *D. deltoides*, a British species, and the pleasant-eye pinks from *D. plumarius*. This flower, Professor Martyn observes, does not seem to have attracted any notice among our ancestors; and it is only within the latter part of the 18th century that pinks were much improved and varied, so as to be greatly valued among florists.

It is now much cultivated everywhere, and especially in the manufacturing districts; in the neighborhood of Paisley, it is carried to a high degree of perfection. (See Part 11. Book I. Ch. III. Sec. 3.) The pink is much harder than the carnation, and less liable to the casualties incident to the latter.

6441. Varieties. Parkinson, in 1629, mentions six or eight sorts. Rea, in 1704, says, there are many sorts, but of little esteem. Hogg, in 1820, gives a list of nearly one hundred names, as plain one; they are then esteemed of little or no value; but when they have only partially run, they may sometimes be recovered to their former state, by being planted in a poor dry soil, that will but just afford sufficient nourishment for their existence (see p. 169). Plogg.

6442. The pink is generally divided into two double sorts. One is the stem sort, large and erect, and not less than twelve inches high. The other is a double pink: of this there are many varieties, which are either very double, or nearly so, and are termed the double sorts; in the one the fringes on the edge of the leaf are so fine as scarcely to be discernible; but it would be considered a very desirable object to obtain them perfectly rose-leaved, i.e. with no fringe at all. The broadest part of the lamina, or broad end of the petals (fig. 611 c), should be perfectly white and distinct from the eye, unless it be a baiet pink, that is, ornamented by a continuation of the eye round the (fig. 611 b), both clean, and distinct, leaving a considerable proportion of white in the centre, perfectly free from any tinge or spot. The eye should consist of a bright or dark rich crimson, or purple, resembling velvet; but the number and depth of the same, as well as the degree of the same, would be to equal that of the white, that it may neither appear too large nor too small." (Maddock.)

6443. Propagation. Generally by pippings for ordinary purposes, sometimes by layers to preserve rare sorts, and by seed for new varieties.

6444. Pippings. The time to commence this operation is immediately previous to or during the bloom, or indeed as soon as the new shoots are grown of a sufficient length for that purpose. Hogg commences about the twenty-first of June. The operation is the same as in piping carnations; only some do not apply bottom heat. This, however, is the more certain mode, and the pippings are ready to remove sooner in a fortnight or three weeks.

6445. By seed. Proceed as directed for carnations.

6446. Nicole has found great advantage from impregnating double and semi-double pinks, with single kinds, both in respect to fecundating more permanent, and producing in consequence more seed; but also in increasing the varieties, or new sorts raised from such seeds. (Cited. Sec. Mem. iii. 270.)
4647. Mode of growing. The common sorts are introduced in borders, and the better varieties in prepared beds. Sometimes rare sorts are planted in pots, but in general they thrive better in the open ground.

4648. Soil. Maddocks says, "A good fresh loamy soil, dug and comminuted about two feet deep, and manured with a stratum of cow-dung, two years old, mixed with an equal proportion of earth, (this stratum five inches thick, the lower six inches below the surface,) is all the preparation or compost that appears necessary for this flower."

4649. General culture. As soon as the pipes are struck and will bear removal, they are to be planted on a bed of common garden-mould, where, in a few weeks, it will easily be discernible which are the strongest plants. These should be reserved for the middle or four foot borders. After the life has been used, the common weeds, such as violets, butes, and omphalodes, may be grown in the paths, and the side beds may be made up with a backing of boards, to come up even with, or one inch higher than its surface; this last, more for the sake of neatness than any particular utility it will be of to the plants.

4650. The plants intended for the principal bed for bloom, should be placed upon it in August, or early in September, as they do not blow quite so well if removed later in the season; they should be placed at about the distance of nine inches from each other, and the bed should be laid rather convex, or round, with a slight and gentle slope, but a very slight slope of the frost. The bed should be kept free from weeds, and its surface stirred up a little if it inclines to bind, or, in other words, whenever it becomes too firm and adhesive. Larger strong plants will put up numerous flower-stems, but it is proper to thin them out a month or six weeks before bloom; in doing which, the larger plants may be removed, the heads only of the others left. If the bed is to contain the whole plant, together with all its best pots; but no plant, however strong, should be permitted to bloom more than ten or twelve blossoms, nor weakly plants more than four or five. In order to obtain them large and well colored, all the small lateral pods should be cut or pulled off; as they never produce any other than diminutive flowers, and at the same time rob the others of a certain part of their nourishment, which, of course, prevents their attaining the size and beauty they would otherwise arrive at.

4651. The largest and most bushy plants do not produce the finest flowers; they naturally put forth numbers of small stems which the roots are not sufficient to produce large blossoms. Strong healthy plants, not too large, and consisting of a capital leading stem in the centre, with but little surrounding increase, are more proper to select for the best bed; these will seldom put up more than one or two stems, which will, however, be very strong, grow tall, and produce three or four blossoms, as large and fine as the sort is capable.

4652. Those pods that appear in danger of bursting should be tied in the same manner as directed for carnations under similar circumstances. Such sorts of pods as are most inclined to burst their pods, sometimes produce larger and finer flowers than others which have smaller pods, because the latter generally lose their pods later than the former. When the calyx is short and round, as it is hardly possible to preserve the latter from bursting, whereby the beautiful circular form which the flower ought to possess is lost. When the calyx is extremely short that it must in every case be drawn in a circular line, it is proper to nick it down at the bottom of each of its indentures, as low as may be deemed necessary, in order to let out petals regularly on every side, and preserve the circular form of the blossoms; for if it is left to nature, the calyx will burst only on one side, and its petals will consequently force their way through that aperture, and produce much disfigurement in the flower possessed of one or more such round and delicate pods (fig. 571. d) will entirely burst from top to bottom on one side, and open so very wide as to suffer almost all the petals to fall out and hang down when they have been in bloom but a short time; such indeed hardly deserve to be classed amongst the best sorts, let their properties, in other respects, be ever so desirable. When the pods are intended for the effect, by placing upon the calyx the thin pieces of card, or stiff paper, cut circular (fig. 612. g), already mentioned (6450); these are to be placed close underneath the guard-leaves, so as to give them sufficient strength, and warrant them from incurring any thing so disagreeable as to the weather, especially after being wet, and must either be taken off entirely, or exchanged for new ones, as they will no longer answer the intended purpose. Some kinds do not require any assistance of this sort, but the greater part not having their guard-leaves sufficiently strong to bear the support of themselves in a horizontal direction, are composition, and by this little contrivance, which, perhaps, by the foregoing description, will not be difficult to comprehend.

4653. At the time of bloom, it is proper to defend the bed by a covering or awning, somewhat similar to that used for the bloom of tulips and carnations; they should, in like manner, be carried up above the flower-stems, and the convolutions should be kept moist; if they are exposed to the weather, especially after being wet, and must either be taken off entirely, or exchanged for new ones, as they will no longer answer the intended purpose. Some kinds do not require any assistance of this sort, but the greater part not having their guard-leaves sufficiently strong to bear the support of themselves in a horizontal direction, are composition, and by this little contrivance, which, perhaps, by the foregoing description, will not be difficult to comprehend.

4654. Hogg observes, that "pinks moved and transplanted in the spring never do well, nor show half the beauty which those did that were planted in September; the laced pinks in particular appear almost pale, and without their distinguishing character: they should likewise never be suffered to remain longer than two years without either change of soil or situation."

4655. Emmerton says, "your pink-bed should be top-dressed in the spring, if you have a desire to excel in blooms, with some old night-soil, or sugar-lacker's sweep, finely sifted and soon over it. Your strong-blowing plants should not be allowed to bloom more than eight or ten blossoms, and those that are weaker, of a less size, not more than four." (Treatise on Auricula, &c. 191.)

4656. The double rocket is a biennial or imperfect perennial; a native of Italy, and cultivated by Gerrard in 1597.

4657. The varieties are a white and purple, both very double, and forming a spike of about a foot long, of great beauty and fragrance, and considerable duration.

4658. Propagation and culture. The plant is extremely difficult to preserve, especially near large towns. It does not thrive either near London or Paris; and both capitals, especially the latter, are supplied with it from provincial growers. It is very much grown in the west of Scotland, and the north of Ireland, from which it may be seen in the best perfection, and enjoyed in the flower gardens. Van Mons (Hort. Trans. ii. 153) says it prospers best in a clayey soil, but flowers best in one of a lighter texture, like the lobelia cardinals. The best directions which we have met with for its culture are given by Robertson. (Calcutt Mem. ii. 245.) He says, "The double rocket is a beautiful plant, rather scarce in this part of the country, owing chiefly, I suppose, to florists not being acquainted with a successful way of increasing it. I had a few plants of rocket under my care, and I did them all justice, as I thought, but all would not do; I lost them all. I tried to part their roots, but being small and weak, the slugs eat them all up in a short time; as slugs are very fond of them, especially of their leaves. I tried to increase them by cuttings in the common way, with certain success. This led use to try another
method, which I would recommend as a never-failing way of propagating this beautiful flower. If a person has but one plant of rocket, and is anxious for its flowers, the first thing is, after the flower is beginning to fade, to eat down the stalks and divide the roots into ordinary lengths of cuttings; next to cut off the leaves, and smooth the ends; then to make three slits with a knife in the bark or rind, longways, so as to separate or raise the bark for half an inch in length. When the cutting is inserted in the ground, the loose bark naturally curls up; and it is from this bark that the young roots proceed. The partial separation, and the turning up of the bark, seems to produce a tendency to throw out roots. The cuttings may be put into flower-pots, as they may thus be sheltered during winter with more ease; or they may be placed in the natural earth, provided the soil is light and fresh. Covering them with a hand-glass will forward the rooting of the cuttings; or with the aid of a hot-bed they will succeed excellently. I have used this simple way for six years back, and never without success; not one in twenty having failed. This method, it may be remarked, will hold good in cuttings of stock-geraniums, and double wallflowers.”

**ce, B. P. Lobelia, Fr.; Kardinalsblume, Ger.; Fior Cardinali, Ital. (figs. 613. and 614.)**

6459. There are three species of lobelia which rank high as florists’ flowers.

6460. The common cardinal flower (L. cardinalis) (Bot. Mag. 320. and fig. 613.) has roots composed of many white fleshy fibres, oblong leaves, stalks erect, about a foot and a half high, terminated by a spike of flowers, “of an exceedingly beautiful scarlet color,” appearing in the end of July and August. It is a native of Virginia; and it is found abundantly by the side of rivers and ditches: introduced in 1629. Justice is in raptures with it, describing it as “a flower of most handsome appearance, which should not be wanting in curious gardens, as it excels all other flowers I ever knew in the richness of its color.” There is a dwarf variety, but it is very liable to perish.

6461. Propagation and culture. By seeds, offsets, or cuttings; but the former method produces the strongest plants. Sow in pots of rich earth soon after the seed is ripe, and place them under the protection of a frame. The seeds will appear the following spring; and after they have two or three leaves should be planted in separate small pots, and shifted into larger ones once or twice during the season. Place them in an eastern exposure, and supply them freely with water. Protect, during winter, by a frame; and the following spring, shift them into pots, six or eight inches diameter, in which they will flower. If not much exposed to the sun, they will continue long in beauty. The roots do not last above two or three years; and therefore a succession of young plants, from seed or slips, should be regularly provided. (Miller.)

6462. The fulgent cardinal flower (L. fulgens, W. en.) (Bot. Rep. 659. and fig. 614. a) is a native of Mexico, and was introduced into England in 1809: flowers in July and August. Though a native of a warm climate, it has been found to bear the severity of our winters, by being immersed in water, as an aquatic, and with this treatment has flowered well by the sides of ponds and in cisterns.

6463. Propagation. By suckers or cuttings, which strike with remarkable facility in any shady situation; and by seed. According to Professor Van Hons, “the seed should be sown, as soon as it is ripe, in earthen pans; the earth should be moistened, and after it has imbibed the water, the seed must be spread over it without being covered. The pans should be sheltered from the frost, and the young plants may be transplanted in April and May. Very few of them remain, more than the second year, with this covering.”

6464. Culture. This plant has assumed a character of uncommon magnificence under the management of Hedges, which is thus detailed by Sabine: “In October, he takes off the suckers, which are thrown up from the roots of the old plants, and puts them into small pots, one in each pot, and keeps them in a cold-frame till the middle of January; he then removes them into a cucumber-frame, where the heat is kept up to 65 degrees of Fahrenheit’s scale, by linings of hot dung: a pine succession stove of the same temperature will equally suit them. In the middle of February, they are shifted into pots a size larger; and at the end of March, or in the beginning of April, they are again moved into larger pots, and in the middle of May they are a third time shifted; the pots to be used for this last shifting are twelves. As soon as the plants are well rooted, after the last removal, they are carried into a peach-house or green-house, in which they continue till they flower, and are hardly enough to bear the open air. When they are preparing to throw up their flowering stems, and during their growth, it is necessary that they be kept very moist, which is effected by putting pans under the pots, and keeping the pans constantly filled with water. The plants thus managed, begin to flower early in July, and the spikes continue to blow, and are covered with flowers throughout the autumn. The compost used in the pots is formed of equal parts of brown or yellow loam, and of leaf or bog mould, to which is added sand, equal to one fourth of the previous composition, the whole being well mixed together. The plant of Lobelia
fugens, which was exhibited to the Society on the 19th of last month, by Hedges, had been managed as above directed; but as no notes of its size and height were made at the time, the following dimensions have been calculated from measurements taken later; the height of the central spike was five feet and a half; the shoots from the bottom and sides of the main stem were in number seventeen, rising together round the principal stem, to the height of forty feet and a half. Hence, states, that the plants were in the two preceding years, much taller than that now described. Some few plants were observed to be rather shorter, and to have a more bushy appearance; this is produced by stopping the centre stem, after the last shifting, by which the side shoots become more vigorous and fuller of flower, and in this state they form handsome companions to the flowering plants of Chrysanthemum pyreutus; and the beautiful spikes of blue flowers agreeably contrast with the brilliant scarlet of the lobelia."

Her TRANS. ii. 400)

6465. The splendid cardinal flower (L. splendens, W. en. (Bot. Reg. 60. and fig. 614. b), a native of Mexico, and introduced in 1814, may be treated like L. fulgens; and the blue cardinal flower (L. siphilitica) (Jac. Ic. hi. t. 597.), a native of Virginia, and introduced in 1655, may be treated like L. cardinals.

6466. The pyramidal bellflower, in its cultivated state, has thick ramose roots, which are milky; oblong leaves; and strong stalks, four feet high, from the sides of which the flowers are produced for more than half their length, forming a sort of pyramid. The most common color is blue, but there is a variety with white flowers. It is a native of Istri and Savoy, and was cultivated by Gerrard in 1596. Formerly it was in demand as an ornament to halls, and for placing before chimneys in summer, being planted in large pots, and trained in the fan manner, so as to cover a large surface. In the shade it continues in flower for two months or more.

6467. Propagation and culture. By seed, cuttings from the stem, or by dividing the roots; the last method produces the strongest plants in the shortest time. The season for this operation is after the bloom has faded in September; the sections are to be planted in pots, and protected by a frame during winter. In spring they may be transplanted into large pots, and in the beginning of summer into still larger ones, in which they are to flower the summer following.

6468. By seeds. The plants so raised, Miller says, are always stronger, and the stalks rise higher, and produce a greater number of flowers. Good seeds are to be obtained by placing a strong-flowering plant in a warm situation against a wall or under a glass case. They are to be sown in pots of light earth soon after being gathered, protected by a frame during winter, and will come up in spring. When the leaves develop from the seed, they are to be planted in light sandy earth, without any mixture of dung, which is a great enemy to this plant. Here they are to remain two years, being protected in winter by rotten tan; they are then to be removed to their final destination in September or October, and the year following, being the third from sowing, they will flower. The plants, Miller observes, of this species, as of many others which have been long propagated by roots, offsets, or cuttings, do not so readily bear seed as those which have been raised from seed.

6469. The C. Carpathica, grandiflora, and several other very showy species, may be similarly treated.

6470. The Chinese chrysanthemum is a fibrous-rooted half-hardy perennial, with pinnate, gashed, serrated leaves, leafy stems, from three to four feet high, and flowers generally on solitary peduncles. It is a native of China, where it is highly prized and extensively cultivated as an ornamental plant, and was introduced in 1764. Here it contributes greatly to the beauty of the flower-garden in a fine autumn, and of our conservatories in November and December, when scarcely any other plants are in flower.

6471. Varieties. The Chinese are supposed from good authority to have fifty varieties or upwards: there are twenty-three sorts described by Sabine, as having flowered in this country, and there are a number more, of recent introduction, which have not yet flowered. Through the exertions of the Horticultural Society, and some nurserymen, and private individuals, it is expected all the Chinese sorts will soon be imported. Sabine describes as having flowered in the garden of the Horticultural Society, and as to be procured in the nurseries, the following:

(Sabine, in Hort. Trans. vol. iv. p. 234. & vol. v. p. 149.)
6472. **Propagation.** By dividing the root, by suckers, and by cuttings: the latter is the best mode, as producing plants less likely to throw up suckers. The cuttings are usually taken from the side branches in August, planted in shallow pots, placed in a warm shaded spot, and covered with a hand-glass. In a month or six weeks, they will have struck, and are then put into pots of the smallest size, and put in a warm situation, where they remain till November; they are then placed under a frame for the winter.

6473. **The soil used generally for the chrysanthemum, is two thirds of turfy or virgin loam, and one third of leaf-mould or decayed dung.**

6474. **Culture in pots** In April, the cuttings of the preceding autumn are shifted into No. 32 pots, and set out into a well sheltered south border, on a bed of scorpio, for the summer. About the beginning of October, when the flower-buds are formed, they are taken into the green-house, on the stage of which they are exposed as much as possible to the air, both night and day, in good weather, but protected by the lights from wind, rain, and frost. The Chinese also propagate the chrysanthemum by cuttings; but, they take them off in May, strike them as we do, and then put each plant in a small pot, in which it flowers the succeeding autumn. By this means the plants are much dwarfer than ours usually are, and instead of having great part of their stems naked, or covered with withered leaves, they are clothed with green foliage from the ground to the flower. In order that the blossoms may be strong, they pinch off all the flower-buds, excepting three, or five, or sometimes only one, as soon as they appear, and are liberal in the use of liquid manure; those which remain are as large and fine as are produced by the most bulky plants. (Wells, in Hort. Trans. vol. iv. 571.) This is by far the most simple, elegant, and economical mode of propagating this beautiful flower; it has been practised several years by the Comte de Vande, at Bayswater, as well as by others in this country, and whenever it is generally known will be as generally adopted. All suckers should be removed, only one or three stems trained erect, and branching regularly on all sides. The side branches and top, or head, should be so arranged and adjusted by a nice application of black threads and wires, attached to the main prop as to render the figure of the entire plant perfectly symmetrical. Three stems may be trained, though one is better than three, because it will grow stronger: but three are better than two, which do not compose a whole; and better than a greater number than three, because unity departed from, there is no limit to irregularity. One and three are unity; because one is complete, and three has a beginning, middle, and end. All possible numbers besides, either fall short of or exceed unity: they are irregularities, and irregularities are redundant and infinite, and therefore unsatisfactory to contemplate.

6475. **Culture in the open border.** Many of the sorts may be planted out in warm borders, or compartments, or against walls, and will flower well in fine autumns; but their roots require protection through the winter, and they should be renewed about every two years; for as they increase much in size by suckers from the roots, the plants, if left for a longer period, become unsightly, and produce small and imperfect flowers. The early flowering varieties, as the purple, changeable white, rose, and buff, seem the hardest and most suitable for borders. (Sabine, in Hort. Trans. vol. iv. 323.) To look well in the border the plants should be large, and with many stems; their flowers are consequently more numerous, and produce a greater effect at a distance. The appearances of the flowers on many of the kinds is very different when blossoming in the borders from those which expand under glass, so much so, that they might be easily mistaken by an unexperienced observer for different varieties. (Hort. Trans. vol. v. 162.)

**Subsect. 23. Hydrangea. — Hydrangea hortensis, L. (Bot. Mag. 438.) Decan. Dig. L. and Saxifragae, J. Hydrangelle, Fr.; Kelleinoff, Ger.; and Hydrangea, Ital.**

6476. **The hydrangea** is a very low under-shrub, producing broad green leaves, and cymes of monstrous flowers, like the guelder rose in form, and red in color, changing to white and green. Its native place is unknown; but it is commonly cultivated in the gardens of China and Japan, from whence it was introduced to Kew by Sir J. Banks in 1790. It is much valued as a chamber plant, and in consequence, extensively cultivated near London and most large towns of Europe.

6477. **Varieties.** Soon after it was introduced, some plants were found with blue flowers, which some supposed to be produced by salt or sulphate, and others by oxide of iron. The yellow loam of Hampstead heath and some other places, and some sorts of peat-earth are found to produce this effect; but the cause is not yet ascertained. Dr. Daalen, of Antwerp, finds that turf-ashes, and still more effectually those of the Norway spruce, the wood generally used as fuel by him, applied to the roots of hydrangeas, produced the blue color of the petals. (Hort. Tour, 122.) According to Busch, of Petersburg, "the hydrangea will be turned blue by watering the young plant, the summer
before, with alum-water. Our grey-colored earth, under the black moor-earth, has the same effect, being combined with aluminous salt." (Hort. Trans. vol. iv. 568.)

6478. Propagation and culture. Hedges, who has been "very successful" in treating this plant, gives the following directions. "As a succession of young plants is necessary, I raise some each year by taking, in the beginning or middle of July, young shoots with three or four joints, cutting them off close to the joint which is at the bottom of the shoot; these are planted in rich earth, in a warm border, and covered with a hand glass; they are shaded during the middle of the day, and sprinkled with water from a fine rose watering-pot, two or three times a-week, in the evening, so as to keep them moist: the glass being kept close over them at all times. They will also grow by layers made in July, in the same way as is usual with carnations. The cuttings or layers will be well rooted by the end of August, at which time, or early in September, they must be put singly into small pots, and placed under a frame, which at first must be shut up close; if they can be assisted by a temperate dung-heat, at this time, it will be better for them. In the frame they must be shaded and watered as before. About the middle or end of October, they are to be taken into the green-house, or other shelter, where they can be protected from wet and frost; during the winter, they must be watered once a week or fortnight, as they may require. In the latter end of May or early in June following, they must be turned out into a bed of rich mould, in the open ground, to remain there till September, when they must be taken up and potted, and kept protected from damp and cold, as in the preceding winter. Instead of turning them out, as stated, in the spring, they may be retained in pots; but they must be shifted twice during the summer. By either method fine strong plants will be formed, fit for forcing or turning out in the succeeding spring. If wanted for the borders, let them be put out when all danger of their sustaining injury by frost is over; they will stand the winter in the borders, and will also bear flowers, though not so well as when protected by a house. Those which are to flower in pots, are taken as soon as their buds begin to swell in the spring; all the old mould being removed from their roots, they are planted in fresh earth, in pots of about eight inches diameter at top, and placed in front of the green-house or peach-house; if the plants are not over large, pots of smaller dimensions should be used; these will come into flower in June. Care must be taken to supply them plentifully with water whilst they are coming into bloom, and it is best to place waterpans under the pots to secure a continual supply of moisture. If it is desired to have plants in flower early in the spring, they must be shifted into their new pots in January, and brought forward with forcing heat. The mould I generally give to my hydrangeas is a compost of loam and bog-earth or leaf-mould, with a little sand, well incorporated together; in this they will produce red flowers; if they are expected to blow blue, they must be planted in the pure yellow loam."

6479. The balsam is a tender annual, rising from one to two feet high, with a succulent branchy stem, serrated leaves, and various-colored flowers. It is a native of the East Indies and Japan, where the natives, according to Thunberg, use the juice prepared with alum, for dying their nails red. Cultivated by Gerrard in 1596.

6480. Varieties. These are infinite, but not so marked or permanent as to have acquired names. The seed from one plant will hardly produce two alike. Double flowers are chiefly held in esteem, and especially those that are striped like flukes and bizarre carnations.

6581. Propagation and culture. It can only be raised from seed, which ripens readily from semi-double plants, and should not be less than three or four, or even nine years old, gardeners having experienced that new seed seldom produces double flowers. The best soil is a rich loam, rather lighter than that used for growing melons. At any period between the 1st of March and 1st of May, sow very thin in pots, to be placed in a hot-bed, and near the glass as possible. When the plants are five inches high, transplant into No. 48 pots, one plant in the centre of each pot. As soon as the roots have filled the pots, move them into pots a size larger, and repeat this operation three or four times, till at last they are in pots of eight inches' diameter or upwards, keeping the plants all the while in a hot-bed or pit, and near the glass. Balsams grow four feet high, and fifteen feet in circumference, with strong thick stems, furnished with side branches from bottom to top, and these covered with large double flowers. (Fairwather, in Hort. Trans. ili. 406.)

6482. The Amaranthus, Colosia or cockscomb, Comphreona or globe-amaranth, Mesembryanthemum crystallinum or ice-plant, Solanum melongena or egg-plant, and most other tender annuals, will attain to corresponding luxuriance, if similarly treated.

6483. Knight, in October, 1830, sent to the Horticultural Society a cockscomb (Colosia cristata), the flower of which measured eight inches in width and seven inches in height, from the top of the stalk; it was thick and full, and of a most intense purplish-red. To produce this, the great object was to retard the protrusion of the flower-stalk, that it might become of great strength. The compost employed was of the most nutritive and stimulating kind, "consisting of one part of unfermented horse-dung, fresh from the stable, and without litter, one part of burnt turf, one part of decayed leaves, and two parts of green turf, the latter being in lumps of about an inch in diameter, in order to keep the mass so hollow, that the water might have free liberty to escape, and the air to enter. The seeds were sown in spring rather late, and the plants put first into pots of four inches' diameter, and then transplanted to others a foot in dia-
PRACTICE OF GARDENING. Part III.

6484. The mignonette is a trailing hardy annual, a native of Africa, and introduced in 1752. It is "the Egyptian bastard-rocket, with most sweet-smelling flowers," of Justice, and the Dutch florists of his day. The flowers are highly odoriferous, and the plant in pots is in universal request, at all seasons of the year, for placing in rooms.

6485. Varieties. There is a sub-biennial semi-frutescence variety, rather more odoriferous than the common sort, which forms an elegant winter plant for the drawing-room, but which is not yet in very general cultivation.

6486. Propagation and culture. Rishon, who cultivated this plant extensively for the London market, gives the following instructions, as applicable to the common variety: "To obtain fine plants, strong and ready to blow, during the winter, and through the months of January and February, the seed should be sown in the open ground the end of July; by the middle of September, the plants from this sowing will be strong enough to be removed into pots; for a week after this removal, they must be shaded, after which they may be freely exposed to the sun and air, care being taken to protect them by frames from damage by heavy rains, and from injury by early frosts, until the beginning of November, at which time many of them will show their flowers; and they should then be removed to a green house or conservatory, or to a warm window in a dwellinghouse, where they will branch out, and continue to blow until the spring. The crop for March, April, and May should be sown in small pots, not later than the 25th of August; the plants from this sowing will not suffer by exposure to rain, whilst they are young; they must, however, be protected from early frosts, like the winter crop; they are to be thinned in November, leaving not more than eight or ten plants in each pot; and at the same time, the pots being sunk about three or four inches in some old tan or coal-ashes, should be covered with a frame, which it is best to place fronting the west: for then the lights may be left open in the evening, to catch the sun whenever it sets clear. The third or spring crop should be sown in pots, not later than the 25th of February; these must be placed in a frame, on a gentle heat, and as the heat declines, the pots must be let down three or four inches into the dung-bed, which will keep the roots moist, and prevent their leaves turning brown, from the heat of the sun, in April and May. The plants thus obtained will be in perfection by the end of May, and be ready to succeed those raised by the autumnal sowing." (Hort. Trans. ii. 375.)

6487. The tree-mignonette, according to Sabine, "is to be propagated from seeds sown in spring; it may also be increased by cuttings, which will readily strike. The young plants should be put singly into small pots, and brought forward by heat, that of a gentle hot-bed being preferable, but they will grow well without artificial heat. As they advance, they must be tied to a stick; taking care to prevent the growth of the smaller side shoots, by pinching them off, but allowing the leaves of the main stem to remain on for a time to support and strengthen it. When they have attained the height of about ten inches, or more, according to the fancy of the cultivator, the shoots must be suffered to extend themselves from the top, but must be occasionally stopped at the ends, to force them to form a bushy head, which, by the autumn, will be eight or nine inches in diameter, and covered with bloom. Whilst the plants are attaining their proper size, they should be shifted progressively into larger pots, and may ultimately be left in those of about six inches in diameter at top." (Hort. Trans. iii. 181.)

Sect. II. Border-Flowers.

6488. Border-flowers are hardy plants, with showy blossoms, of easy culture, and their use in floriculture is to decorate the flower-garden, shrubbery, and other spots or borders considered as ornamental. We shall take them in the order of perennials, bulbs, biennials, hardy annuals, and half-hardy annuals; and arrange each of these subdivisions according to their time of flowering, heights, and colors: indicating by letters those requiring peat-soil (p); such as are rather tender (t); such as are most showy (s); and such as continue in flower for two or more months (S). At the end of each subdivision we shall give its general mode of propagation and culture. It may be added, that most of the plants mentioned as flowering in any particular month will often come into flower the month preceding, and continue in bloom during one or more of the following months. Hence the importance of selecting such flowers as are at once the most easy of cultivation, beautiful in appearance, and that continue longest in flower.
**BORDER-FLOWERS.**

**SUBSEC. 1. Species and Varieties of Perennial fibrous, ramose, tuberous, and creeping rooted Herbaceous Border-Flowers, arranged as to their Time of Flowering, Height, and Color.**

6490. Propagation of perennial herbaceous plants. All the modes of propagation, excepting such as are applicable only to woody plants, may occasionally be adopted; but the most general practice is by dividing the root, by suckers or offsets, and by seed; the other modes are by cuttings of the stalks, shoots, or roots, and by layers.

6491. By dividing the root. This mode is applicable to nine tenths of hardy herbaceous plants. The plant may either be taken up, divided with the knife, and a portion replanted to continue the species in the spot allotted to it; or, the earth may be partially removed, and part of the roots and crown cut off to make new plants. The sections may, if well rooted, be planted at once where they are to remain and flower, or, what is preferable, they may be planted for one season in nursing-beds in the reserve-garden, and prevented from flowering that season by pinching off the flower-buds as they appear. The common season for performing the operation is spring, when the plant is beginning to push, or in summer or autumn immediately after it has flowered. The latter is generally the preferable period, unless the plants very late, in which case the sections will not have sufficient time to form roots for their support during winter.

6492. By suckers or offsets. This mode is also applicable to nine tenths of common herbaceous plants; the best time for removing them is in spring, or early in summer, after the plant has begun to grow. Plant them in the nursing-department, and pinch off their flower-buds, that they may flower strongly next season when removed to their final destination.

6493. By seed. This mode is applicable to all the single-flowering kinds, but is only adopted with a few species, which are otherwise difficultly multiplied. Collect the seed from the flowers which expanded first, as being generally the strongest. If it is ripe before August, it may be sown in the same season, but if otherwise, it will be preferable to defer sowing till the following spring. Sow on beds of light earth, thinly covering according to the size of the seed, and prick out the plants once or twice according to their strength, size, or weakness, so as they may be fit to remove to their final destination in August or September. They will flower strongly the following year, and probably may show some new varieties.

6494. By cuttings from the side-shoots or flower-stems. This mode is applicable to a number of the more delicate and double-flowering herbaceous plants, as to scarlet and pink lychens, double rockets white and yellow, some hollyhocks, and a variety of others; but more to biennials and annuals than to perennials. The cuttings may be taken off at any time when the shoots are tender and properly prepared, and planted in sandy loam in a warm situation, but shaded and covered with a hand-glass. Afterwards transplant them in the nursery-department, and again the same season where they are finally to remain. They will blow freely the summer following.

6495. By cuttings from the root-shoots. This is applicable to some sorts which do not multiply fast at the root, or whose rooted stolones or suckers do not make handsome plants; as to some species of alium, statice, silene, &c. The early part of summer is, in general, the most fitting season for performing the operation; plant in sandy loam under a hand-glass, and shade in the sunny part of the day; then transplant in the nursery department for a few weeks, when the strongest plants will show themselves, and may be removed in September to their final destination. They will blow strongly next year.

6496. By cuttings of jointed root-shoots or pipings. This is chiefly applicable to the diandthus tribe, alium, salamandra, the striped grass, or any other grasses or reedy plants. Proceed as in piping pinks or carnations (6412.); but no bottom heat will be required for the sorts that come under this section.

6497. By cuttings from the roots. This is strictly applicable only to such plants as form buds on their roots, as to most of the rubiaceae, to the mints, piperiibiums, &c. About midsummer is the earliest period at which the creeping roots are generally fit for this purpose; but with some others, as gallium, osmundum, &c, it may be done in spring
Plant the cuttings in the shade, and afterwards transplant and treat them like cuttings from the flower-stalks or root-shoots.

6498. By layers. Such plants as cannot easily be propagated by any of the foregoing modes may be increased by layers; such as the carnation, some species of salvia, sibbaldia, sibthorpa, some silenes, &c. Commence the operation when the plant begins to flower, and when the layers are rooted, treat them as directed for pipings.

6499. General culture of fibrous-rooted herbaceous flowers. Autumn, after the plant has done flowering, or spring, when it has begun to grow, as has been already observed (6189.), are the seasons for planting or transplanting. The general culture is, stirring the soil; renewing it according to the kind of plant (6188.); taking up overgrown plants, reducing them, and replanting (6190.); sticking, pruning, trimming, removing all useless, decayed, injured, or diseased parts; and supplying blanks. (6192.) The general management consists in attending to order and neatness. (6201.)

6501. Propagation of bulbous-rooted flowers. By offsets or by seed; the whole, with the exception of the cyclamen, and one or two others, are propagated by offsets, which are to be taken off when the plant is in a state of rest, which happens in most sorts after it has done flowering; afterwards they are to be planted in a nursery-bed for one year, and where they are finally to remain the year following. Autumnal-flowering bulbs are not in a state of rest till the beginning of the following summer: as the colchicum, autumnal-flowering crocuses, amaryllis lutea, and a few others. These, therefore, are to be taken up when their leaves begin to decay early in summer, their offsets separated and planted in the nursery-department, and the parent bulbs replaced in a month or six weeks, in order that they may have time to establish themselves and flower before winter.

6502. General culture and management. Bulbous-rooted flowers differ from others in requiring in their cultivated state to be frequently taken up and replanted. Fibrous-rooted plants which grow much at the root, require this occasionally; but almost all bulbs frequently. The reasons are, that in deeply comminuted rich ground, most sorts, but especially those which form their new bulbs beside the others, multiply so fast that the bulbs become crowded, small, and unfit to send up strong flowers; that many sorts, as in narcissus, tulip, &c. which form their new bulbs under the old one, send down their bulbs at last so deep that they at first come up weakly, and afterwards cease to appear at all, as in the bulbous-rooted irises, colchicum, &c.; and that some, on the contrary, which form their new bulbs over the old ones, send them up at last above the surface, as in crocus, gladiolus, &c.; and are consequently killed by the frost or drought. Hence the finer bulbs of florists require to be taken up every year, and all the border-bulbs at least every three or four years. The time to do this is when the plant has flowered and the leaves have begun to decay. No bulb should be taken up for any purpose, or injured in its growth in any way while the leaves are green; for it should ever be remembered by gardeners, that it is the leaves which bring the root to maturity and prepare it for flowering the following year. If these are injured or cut off, or if the plant is transplanted, unless with such a ball as not to touch any of its fibres while in a growing state, the bulb will not recover so as to be able to flower for at least one year, and probably two or three. The time for keeping bulbs out of ground depends on their habits as to flowering. The object is to heal the wounds made by removing the offsets, and perhaps by setting the bulb more completely in a state of rest, to render it more excitable when planted. A month will in general be sufficient for this purpose, and more cannot be allowed with safety to the autumnal-flowering bulbs: more than three months is more likely to be injurious than useful to most sorts, though hyacinths, and other bulbs which form articles of general commerce, are frequently kept out of the soil half the year: when planted so late, however, they seldom flower well the first season, and commonly not at all for a year or two afterwards. The taking up, drying, and replanting of border-bulbs must be attended to by the flower-gardener with equal regularity, though not with equal frequency as the finer, select, or florists' bulbs: the offsets may be planted in beds in the reserve-garden, if wanted for stock; and the soil of the spot where the plants stood in the border renewed according to its kind, and the flowering-bulbs replaced. Some bulbs multiply so fast by throwing out offsets, that they soon cease to send up flower-stems. Of these may be mentioned the ornithogalum umbellatum, luteum, and some other species; some species of scilla, muscari, iris, allium, oxalis, and others. These should either be annually taken up, their offsets removed, and the parent bulb replanted; or the offsets, as soon as they send up leaves, should be destroyed. Indeed, whenever strong-flowering bulbs is the principal object, the offsets should never be allowed to attain any size; but as soon as they indicate their existence by showing leaves above ground, they should be removed with a blunt stick, or in any way least injurious to the parent. By this practice a great accession of strength is given to the main plant, both for the display of blossom during the current season, and for invigorating the leaves to prepare and deposit nutriment in the bulb for the next year. In pursuance of the same objects, every flower should be pinched off as soon as it begins to decay, but the flower-stalk may remain till it begins to change color with the leaves. Some bulbs are greedily sought after by vermin: as the crocus and tulip by the mouse and water-rat; the snowdrop and some of the narcissi by the snail and slug; and the hyacinth by a particular sort of grub-worm. We know of no method of mitigating these evils but by catching the mice and rats, gathering the snails, and taking up, drying, and replanting in fresh soil, the roots attacked by worms or insects. The snail is perhaps the worst of these vermin, and, fortunately, it may be most effectually kept under, by scattering leaves of the brassica tribe (of any variety) over the ground, and picking from them, every morning, the snails which have fixed on them during the night.

6503. Most bulbs force well; to expedite this, retard the bulbs by keeping them in an ice-house till the autumn of the second summer; put them in water-glasses or pots in September, and they will be in full blow by Christmas.

6505. Propagation and culture of biennial border-flowers. They are all raised from seed, but some of the finest double varieties are continued by cuttings. The seed of such sorts as ripen by August may be sown immediately after it is gathered; but the seed of those sorts which ripen later should be preserved till the following spring, and sown in May or the beginning of June. Sow thinly in beds in the reserve-garden, transplant into other beds when the plants are a few inches high, and in September or October remove the plants to their final destination. If this be, as it most generally will in the mingled flower-border, to provide a succession of the same sorts, then it can only be done in the case of those sorts which are done flowering by September or the first of October, and the others must be removed early in March with balls. Great care is requisite in removing some sorts which have large tap-roots, as eleothena, holly-hock, lavatera, &c., for if materially checked they will not flower strongly. The best mode is to nurse these sorts in large pots, and transplant them in October or February, with their balls entire. The sorts continued by cuttings are chiefly fine double varieties of wallflowers, stocks, rose-campions, &c. The cuttings may be taken from the flower-stalks, or the root-shoots, early in summer, put under hand-glasses, and otherwise treated as cuttings of perennials. If the cuttings of some sorts, as dahlia, chrysanthemum, lobelia, &c, are taken off early in the season, they will flower in the autumn. The plants once placed where they are to remain, their general culture and management is the same as for the perennial border-flowers. (6187.)

</table>

6307. Propagation and culture of hardy annual flowers. They are all raised from seed, though occasionally some fine varieties of chelantus, viola, &c. are preserved by cuttings. The seed is generally sown in March or April, and in patches or rings in the borders where the plants are to flower. The ground is previously stirred and made fine; the patch is sown of a circular form of six or eight inches' diameter, or a row only is sown in the circumference of the circle, the seeds covered according to their size, and the plants, when they are an inch high, thinned out to one, three, five, seven, or more, according to their kind. This, and occasionally stirring the soil, with staking, &c. as in perennial flowers, is all the culture they require. Sometimes the whole, or many of the sorts, are sown in the reserve-garden, and transplanted where they are finally to remain. This answers well for such sorts as the lupin, sunflower, and sweetpea, but is rather precarious with such early flowering and short-lived sorts as annual stocks, candytuf, Venus's looking-glass, &c.
of PRACTICE.

6508. Seed may be saved either from the top and first-expanded blossoms of plants in the borders, or from patches soon in the reserve-garden. For the sake of neatness and beauty, no more flowers on each plant must be allowed to ripen their seeds than is necessary for the supply; it is not always easy to procure from the seedsmen, the simplest, and indeed the most economical mode, is to procure supplies yearly from them.

6509. Some very pleasant conceits for arranging annual flowers are given by Swindon (Beauties of Flora, 1778), a Brentford nurseryman. He gives a copious list of annuals, arranged according to their heights and colors; and by affixing a number to each sort, he can readily indicate on his plans the kinds to be employed, and their relative position. Thus he has 89 sorts of common hardy annuals, arranged in six different classes, for six different ranges, in borders, as follow:—

**First range, which grow from 5 to 12 or 14 inches high.**
1. Cape marigold; purple and white.
2. Large catarpillar; yellow, and singular pod.
3. Venus’s looking-glass; light purple.
4. Rain’s horns; yellow, the pod its beauty.
5. Venus’s navel-wort; clear white.
6. Round snails; yellow, and singular pod.
7. Dwarf variegated lychens; crimson and white.
8. Heart’s ease; purple, adown.
9. Half moons, or moon-trees; white, and singular pod.
10. Blue meadow lychens; sky-blue.
11. Dwarf virgin’s stock; pale rose-color.
12. Small hedgegogs; yellow, and singular pod.
13. Woodroof; light blue.
14. Red hawkweed; pale red.
15. Large hedgegogs; yellow, and singular pod.

**Second range, which grow from 12 to 18 or 20 inches high.**
16. Oak of Jerusalem; yellowish, with fragrant smell.
17. Small white candelabrum; clear white.
18. Large horned devil’s-head; yellow, and singular pod.
19. Convolvulus minor; bright blue with yellow eye.
20. Large purple candelabrum; light purple.
21. White lobel’s catchfly; flesh-white.
22. Annual snapdragon; purple and yellow.
23. Large white candelabrum; clear white.
24. Scarlet, or wing peas; dark and light red.
25. Striped convolvulus; fine blue and white.
26. Red lobel’s catchfly; bright red.
27. Dwarf nasturtium; deep orange.
28. Broad Spanish nasturtium with brown seed; deep blue.
29. Red ros adonis; dark red.

**Third range, which grow from 20 to 24 or 26 inches high.**
30. Spanish nigella, with black seed; light green.
31. Spanish hawkweed; pale-yellow, and purple eye.
32. Blue Moldavian balm; deep blue, and fine scent.
33. Large rest-harrow; light red.
34. Large Roman nigella; white mixed with blue.
35. Long-horned devil’s-head; dark orange.
36. Nettle-margaron; yellowish, no smell but to the over.
37. Rocket-larkspur; pink and white.
38. Sweet-scented lupines; bright yellow.
39. White Moldavian balm; white, fragrant and smell.
40. Dutch lupines; fine blue.
41. Annual barks ear; dull yellow.
42. Purple jacobs; purplish-red and yellow eye.
43. Dutch ranunculus-marigold; sulphur-color.
44. Red-topped cary; pale-reddish, and pink leaves.

**Fourth range, which grow from 2 to 2½ or 3 feet high.**
45. Belvedere; yellowish, a handsome white plant.
46. Small variegated corn-poppies; various, red and white, &c.
47. Double upright larkspur; blue, bluish, &c.
48. Cynus minor; blue, crimson, &c.
49. Thorn-apple; white, and singular pod.
50. Round snails, dark, crimson, &c.
51. Crown-larkspur; pale pink, spotted, &c.
52. Hemlock scabious; pale blue, and globular pod.
53. Portugal lychens; pale red.
54. Small blue lupines; bright blue.
55. Loves lies a-bleeding; light red.
56. Ranunculus-marigold; deep orange.
57. Honeywort; dark purple, and singular shape.
58. Strawberry-sparine; bright-red fruit.

**Fifth range, which grow from 3 to 4 feet high.**
59. Venetian small-flowered mallow; purple-white.
60. Double crimson jargon-leaf poppy; dark crimson.
61. Tall narrow-leaf wallflower; bright yellow.
62. Red and white scabious; deep crimson.
63. Double striped carnation-poppies; red and white.
64. Red hawkweed; pink and white.
65. Red lavaters; light changeable red.
66. Branching larkspur; blue and white, &c.
67. Tall white lupines; pale white.
68. Double black carnation-poppies; rose-color.
69. Small Peruvian margin; yellow.
70. Lord Anson’s peas; fine blue.
71. White larkspur, snow white.
72. Dwarf double and quilled yellow sunflower; deep yellow.
73. Bladder ketmis; pale-sulphur and purple eye, with singular pod.

**Sixth range, which grow from 5 to 7 or 10 ft. high.**
74. Tall double yellow sunflower, with black seed; deep yellow.
75. Painted lady sweet-scented peas; pale-red, and white.
76. Small redpaint bells; crimson.
77. Purple sweet-scented peas; dark and light purple.
78. Red plum flowers; black and white.
79. Double red-paint bells; crimson.
80. White crimson peas; clear white.
81. Large Indian nasturtium; dark and light orange.
82. Red plum flowers; single.
83. White sweet-scented peas; clear white.
84. Spanish larkspur; fine crimson.
85. Tall oriental mallow; purple.
86. Painted lady tanger peas; pale-red and white.
87. Scarlet beans; fine scarlet.
88. Curled-leaf upright mallow; white tinged with purple.

6510. In borders he sows in rows, or rather at six different distances from the walk, according to the different ranges, thus:

6511. For a circular clump, or cone of flowers, including all the 89 different sorts, he arranges the six heights in six concentric circles (fig. 616.), placing a persicaria and oriental mallow in the centre. The general appearance (fig. 617.), he says, is "the same on every side, rising gradually from the edge up wards, the highest plants meeting nearly in a point at the centre, and no two flowers of the same color or shape being seen together." (Beauties of Flora, &c. p. ii.) To those who have but a limited space and means, or who have few perennial flowers; to persons in remote situations in the country; to residents in the colonies; and to female and infant gardeners, the above list and modes of arrangement afford a source of considerable show and amusement at a very small expense,—little trouble, and, being annuals, little loss of time. Swindon was in the habit of supplying masters of ships with packets of these seeds for all parts of the world.

6513. Propagation and culture of half-hardy annual flowers. These are raised from seed, which is sown in March in a hot-bed; and the plants, when an inch or two high, are transplanted into another bed of very moderate temperature. Here they may remain till the middle of May, or till all danger from frosty nights is over, and be then transplanted to where they are to flower in the borders, and treated in all respects as hardy annuals.

6514. To see seed. In dry seasons, most sorts will ripen seeds, if permitted, but in wet seasons, unless the plants have been well forwarded in spring, and planted in a dry soil and warm situation, the seed will not be matured. In such cases, a hand-glass supported over the flower is of use; or some may be removed with balls into large pots, and placed in an airy pit, frame, or green-house. In the northern and western counties, where the climate is cold and moist, half-hardy annuals never ripen their seeds in any year; and supplies are therefore annually obtained from the London seedmen.

SECT. III. Flowers for particular Purposes.

6515. The particular purposes to which flowers are sometimes applied, may be either the concealment of local defects, or the production of local beauties. Among the former may be classed, covering naked walls, posts, parts of ruins, or other upright objects; concealing horizontal defects, as naked sub-barren spots, unsightly banks, &c., producing vegetation under the shade and drip of trees; among the latter, ornamenting water with flowering plants; ornamenting rocks, or assemblages of stones formed in immitation of rocks; preserving a green appearance on beds or borders during winter; forming edgings to beds or borders; furnishing odors; and presenting botanical, curious, and scientific assemblages.
SUBJECT 1. Flowers which reach from five to seven feet in height, for covering naked Walls, or other upright Deformities, and for shutting out distant Objects which it is desirable to exclude.

6516. The flowers suited for covering upright deformities are the climbers and twining plants: the former to be supported by spray or trellis-work, or nailed in the manner of wall-trees, and the latter by rods. We shall confine ourselves in this subsection to those plants already enumerated in the preceding section, to which the botanist will best be able to add others from the more extensive catalogues.

SUBJECT 2. Flowers for concealing Defects on Horizontal Surfaces: as naked sub-barren Spots, unsightly Banks, &c.

6517. The flowers suited for covering horizontal deformities are creepers and trailers, of which we shall here bring together the names in the common sorts:—

Creepers and trailers which are perennials. Ajuga reptans, v. flo alba. Anthemis nobilis, n. flo. pleno. Arenaria montana saxatilis, Asperula odorata, taurina, tinctoria, Cerastium latifolium, repens, Circaea alpina, ketuliana, Fragaria vesca, flo. var. v. monophylla, Galium boreale, cruciatum, rubioides, vernum, Geum repandum.

SUBJECT 3. Flowers which will grow under the Shade and Drip of Trees.

6518. Flowers which will thrive under trees are of particular value. In improving neglected flower-gardens and pleasure-grounds, it is a common complaint that new things cannot be brought forward on account of the shade and drip of trees. This section, and the corresponding one of hardy shrubs, will, it is hoped, aid in removing that complaint, which can only have arisen from ignorance of the native habitations of plants. It is proper to observe, however, that there is scarcely any, indeed we may say, no plant, that will thrive under a dense evergreen fir-tree clothed with branches down to near the surface: moss is all that can be there expected; or, if somewhat open, the pyrola, box, and juniper will exist. Where trees are so dense, however, no plant or shrub can be desired under them.

Perennials. Anemone nemorosa, n. flo. pleno, pennsylvaniae, ranunculoides, Arum mucatulum, Asarum europaeum, Asperula laviegeta, odorata. Atropa belladonna, Betonica officinalis, Bupleuri anisatum, camporum, opiparious, Cirsium alpinum, iute-tiana, Clematis recta, Convalaria multiloba, verticillata, Fragaria vesca, v. fol. var. v. monophylla, Geranium sylvaticum, s. flo. pleno, Geum urticae, Helichrysum petiolatum, Hydrastis, Ilex mas, Imperatae oruthifolia, Lathyrus tuberosus, Lysimachia

SUBJECT 4. Flowers for ornamenting Pieces of Water, or planting Aquariums.

6519. Flowers for water or watering-places are of two kinds, aquatics, to plant in the water, and marsh plants, to plant round the margin of the pond, stream, or aquarium. The shape and size of the aquarium (fig. 618) must depend on the extent and style of the flower-garden, of which it forms a part. In all cases the bottom, if not naturally retentive, must be rendered so by a stratum of tempered (or puddled) clay (a); the sides should be formed in terraces, or steps descending towards the centre (b), to hold pots of plants in shallow water, or in deep water in the bulrush, typha, &c. may be planted in the ground, or in large tubs placed in deep water. The margin of the aquarium may either be finished with regular masonry or brick-work; or what, in some situations, has a better effect, with rough stones, conglomerated with the help of cement, or fine stones, in the interstices of which marsh plants will thrive exceedingly. The whole may be surrounded by a gravelly walk (c), raised a few inches above the level of the water. Many of the aquatic plants, as nymphaea, nuphar, menyanthes, villarsia, butomus, and botomias, &c. are highly beautiful; and, considering that some exotic species, as annylobium, liliastrum, (var. alpic.) (619) will thrive in water in our climate, the aquarium ought not to be wanting in any flower-garden.

6590. Propagation and culture. They are propagated by seeds or dividing the root: the seeds being sown and placed under the water. In other respects they require the same general treatment as other herbaceous plants. Some useful remarks on the treatment of the more rare nymphaeas and nuphars by Kent, will be found in the Horticultural Transactions, vol. iii. p. 24.

**622. Marsh plants.** Some of these have been given as border-flowers, and will grow in almost any situation; but others, as the acorus, comarum, litorcilla, &c. will not grow vigorously and flower unless their roots are in soil constantly saturated with water.
523. Propagation and culture. The same as for herbaceous plants, taking into consideration the differ­ence in the soil and site.

**SUBJECT 5. Flowers for ornamenting Rocks, or Aggregations of Stones, Flints, Scoria formed in imitation of Rocky Surfaces, &c.**

6294. In strict propriety, mountain or rock plants only should be introduced on artificial rock-work; but natural mountains and rocks are always moist and cool, and the plants which have their habitations there would not always thrive on dry ridges of earth and stone. On a small scale, therefore, choice is gener­ally made of such plants as are not tall and rampant, and as grow naturally in a dry soil. In the follow­ing list, as in the others, the most ornamental of them are distinguished by a figure (s), and those which flower the greater part of the year by a figure (3), &c.

**Perennials.** Achillea alpina 5, montana, Ajugo alpina, pyramidalis 5, Alchemil­la alba, potentilla, Alysian montanum, murele, saxatilis, Anemone alpina, apennina, baldensis, pulsatil­la 5, major, 5, Anthemis montana, Anthrichum al­pnum, Aquilegia alpina, Arabis alpina 5, bellidifolia 5, lucida 5, sibí­rica 5, Armeria montana 5, saxatilis 5, Arcia montana 5, Artemisia rupe­stit, Asperula alpina, hypericfolia, montanus 5, uralensis, Anthe­mila alpina, Cistanthe pyr­rochly, Phyteuma alsace, Fim­i­nula saxifraga, Podalyria australis 5, Potentilla rupestris, Rubus arcticus 5, chamomorius 5, rosalactis 5, saxatile 5, Saxifraga albo­rifolia 5, nivalis, op­positefolia, pennylavica, petra, rou­tenfuran, semen for­titudinean, glaucum, hybridam, ru­pestre, sexanguliare, villorum, Silene alpina, rupestris, saxatilis, saxifraga, Telephium imperialis, Teucrium mon­tanae, Thlaspi alpestre, Thymus vulgaris, Tormentilla reptans, Trifil­ium alpestre, montanum, reyns ma­culatum, Valeriana montana, pyre­nica, Veronica montana, saxatilis, Viola lutea, montana.

Rubus. Alchemilla pyrenaeum, Fritillaria pyrenaica, Onithogamum pyrenacum, Geranium alpestre, Valerica 5.

Bianuiss. Alysium doudeum 5, Cam­panula cervina 3, thymocephala 5, Car­nus marianus, Carina vulgaris, Cheristus cheiri, ineim, Coche­lia, artis gladiola, Digitalis purpurea, p. fi­ulo, Echium vulgaris, Gra­phaphis lutea alba, Hedyranum coronarium, Marrubium alpynum, Teucrium montana 3, Thlaspi saxatile, Verbena offici­nalis.

Hardy Annuals. Alysium alpynum, Anthriscus cavelorum, Campanula persica, Geranium maculatum, Momentaria eisterum, Reseda odor­ata, Scorzonera pircoides, tingitana, Silene actos, beeh, Trifolium po­lonicum, Vicia laricola.

6295. The ground-plan and figure of the elevation of the rock-work must, as in the case of the aquarium, be made to harmonise with surrounding objects. Simple shapes and surfaces, not too much broken, show the plants to most advantage, and are not so liable to ridicule as imitations of hills or mountains, or high narrow cones, or peaks of scoria in the Chinese manner, which are to be seen in some places. A ground-plan, in the form of a crescent, or of any wave figure, widest towards the middle part of its length, and with the surface not steeper than forty-five degrees (fig. 619), will be found well suited to the

less durable materials, such as bricks, pudding-stone, scoria, &c, which are found in flat country. Sometimes one side of such rock-works may be nearly perpendicular, in which case, if facing the north, it is difficult plastically to suggest vertical masses.

6296. In countries abounding with stone, massy and extensive pieces of rock-work may be formed, and shrubs introduced as well as plants, so as to produce a scene of considerable beauty and interest. Its base, and such parts as are near the eye, may be formed of masses of granite or bassalt; selecting such for the shady side as are already covered with mosses and lichens, especially the lichen atm-flavus, geo­graphicus, venous, stellaris, &c. These vegetables will not grow on sandstone, but seldom on limestone, therefore stones of these earths should be kept as much as possible in the more distant parts, where they will be better covered with shrubs and plants, rooted in proper soil, introduced in the crevices. When works of this kind are extensive, a winding walk or stair may be led over them, and wells, or small reservoirs of water, introduced in some places for mountain bog-plants and aquatics, and for keeping the whole mass moist and cool.

**SUBJECT 6. Evergreen-leaved Flowers, or such as are adapted for preserving an Appearance of Vegetation on Beds and Borders during the Winter Months.**

6297. A due proportion of evergreen-leaved flowers is very necessary for enlivening borders in the winter time, and more especially in dog compartments on a surface of turf, which, without some evergreen plants, oak dreary by contrast with the verdant surface.

Bianuiss. Agrostemma coronarium, c. flo. albo, Anthriscus sylvestris, Sisyrinchium italicus, paniculata 5, Dianthus arme­niae, 5, serpyllus, 5, Dianthus longiloba, 5, Hesperis matronalis, Iberis indiabilis 5, Lavatera arbores, Silene viscosa.
FLOWERS for Edgings to Beds or Borders

6528. The principal plants for edgings, next to the dwarf-box, are the statice armeria, bellis perennis, gentiana acaulis, saxifraga umbrosa, oppositionis, hypanoides, festuca ovina, and other low-growing evergreens. A list of all the Bellis perennis concerns require edgings of flowers. The common and other heaths make very beautiful edgings in parterres of sweet petals.

6529. Flowers with sweet smells are no less desirable than those with fine forms or colors. So little has hitherto been done in the nomenclature and classification of vegetable odors, whether fixed or volatile, that it may be hardly admitted any regulation on the subject, would be advantageous. The pleasures derived from flowers depend on their odors; and that these are very different, every one must have re- marked who has walked in a wood or a garden after a warm shower, or in a dewy summer's evening. Perhaps the best mode to arrange the odors of plants in our present imperfect state of knowledge on the subject, would be to follow the macroscopic smells, as those of the rose, lily, thyme, &c. and the groups together in the same way of our natural orders; and thus we should have rosodora, liliotora, thymotora, &c.; but in default of some such, or any system, we shall here bring together a few names under common received distinctions.

Sticks. Astrantia major, Clinopodium fortis, Ferula alpina, Sideritis, Fritillaria, Allium, various species, Schro- philla aquatica, Anthenis cornu.

9. Other selections of Flowers.

6530. Other selections will readily occur to the florist who is conversant with the ample store of plants at his command; such as double flowers, flowers that continue in bloom the greater part of the year, flowers for peat sols, &c. all which he may select from the indications in the tables already given. He may also select, according to the Linnaean or natural orders, by referring to the tables (588. and 589.) in which the genera are so arranged; or according to the native habitat, native country, year of introduction, or rarity, which circumstances he will find noted in the excellent catalogues of Sweet and Page.

10. Botanical and other Assemblages of Plants.—Dial-Plants, Parasites, Ferns and Mosses, Alpines, and a selection for a small garden.

581. Botanical collections, as well as cabinets of shells and minerals, have been in vogue by the curious since Solomon's time. In many private families there is a taste for scientific botany; in which case the hardy plants of the vegetable kingdom, as far as they are introduced into this country, are arranged in their order according to some system, and either in narrow beds, in which one species follows another; or in groups, on lawn or gravel, in which the species most nearly allied according to the system adopted, are placed together, each group containing an order (fig.553), and all the orders of a class forming a constellation of groups, connected at one point with the preceding order, and at another with that which follows. Sometimes a different arrangement is adopted, and all the plants that can be considered as ornamental are assembled in beds or borders, and all those that are merely curious, as the ferns, mosses, fungi, &c., or used in agriculture or the arts, as the grasses, garden-plants, plants used in dyeing, tanning, &c., are arranged in beds or groups in compartments by themselves. This is in general the most suitable mode for a private garden. With respect to the species to be introduced in these groups, the gardener will have recourse to the tables already referred to, in which, in the Jussieuan table (589.), under Gramineae, Cy- prereae, Juncceae, Rostacaeae, he will find all the grasses; under Filices, all the ferns; under Lycopodinum, the plant-mosses; under Equisetaceae, the equisetums, &c. The economical plants he will find under ger mal system, to which the distribution of the British Flora (573.), and the species he will find enu- merated, and classified, in our Encyclopaedia of Agriculture.

6532. Dial-plants. Among curious collections, it may sometimes be desired to assemble the dial-plants, or such as indicate the hours of the day. An ample list of these has been given by Linnaeus, in the Phil- losophica Botanica; but the following species generally known and easily procured, may be deemed sufficient to complete a botanist's dial in Britain:—

**Note:** The table above lists plants that are common and generally known, and are easily procured. They are used to construct a dial or time indicator in gardens. The specific times correspond to when each plant blooms. Each plant is listed along with its bloom time, and the times are listed in 1-hour intervals from 6 AM to 9 PM.
In both botanic and horticultural gardens, some peculiarities of culture may be required for parasites, ferns, mosses, fungi, and other plants that are associated with the moss and lichen flora. These are generally herbaceous, and the tussocks or tufts of many of these plants, when dry and trimmed, resemble the tussocks of grasses. They are often found in the crevices of rocks or stones, in the crevices of cinders, or on the surface of the soil. Many of these plants are difficult to preserve in a state of cultivation. They are generally found in damp or damp places, and in the crevices of rocks or stones, or in the crevices of cinders. They are generally found in damp or damp places, and in the crevices of rocks or stones, or in the crevices of cinders. They are generally found in damp or damp places, and in the crevices of rocks or stones, or in the crevices of cinders. They are generally found in damp or damp places, and in the crevices of rocks or stones, or in the crevices of ciders.
635. A collection of flowers for a small garden. Having given a selection of the most rare plants, and such as in a state of culture are the most difficult to preserve; we shall conclude with a list of flowers, the most common, hardy, and showy, which flower great part of the year, will thrive in almost any soil and situation, and which are recommended as fit for the commonest description of flower-borders, shrubberies, or parterres.

Flowering from February to May.

Flowering from May to August.

Catalogue of Hardy Trees, with showy Flowers.

6359. All trees may be considered as ornamental by adding to the beauty of landscape; but we mean here to confine ourselves to such as are ornamental, by the conspicuousness of their flowers. These are not numerous; they are all of the deciduous kind, and their time of infulness is limited to two or three months. The principal are the horse-chestnut, acacia, the fruit-trees in their wild state, some species of mespilus, sorbus, cytisus, robinia, &c.; these, with some others which we have arranged according to their height and time of flowering, in order to admit of a selection for the back rows of the shrubbery. None of the few evergreen trees which we possess, have showy flowers, but we have added the names of these, with their heights, to facilitate a selection for mixing with the deciduous sorts in the mingled or grouped shrubbery. We have omitted all those showy flowering and evergreen trees which do not usually attain the height of twenty feet, deserving it more suitable for our purpose to include them among the shrubs of that size. All the useful and curious species of trees will be found in Page's Prodrorum, with their heights, time of flowering, soil, mode of propagation, and other circumstances. In the Arboricultural Catalogue (Part III. Book III. Chap. VIII.), the most useful timber-trees are described, and the shapes of trees, and their colors, and characteristic expressions, are treated of both under Arboricultural and Landscape Gardening. (See Part III. Book III. Chap. II. Book IV. Chap. II.) Much less attention has of late been paid to the introduction of new sorts of trees into this country, than to the introduction of fruits and flowers. The French and Germans seem to excel us in this respect. A considerable number of new sorts of

PROPAGATION AND CULTURE. See ARBORICULTURE. Most of the trees enumerated in both the foregoing sections are highly ornamental as single objects on a lawn; and form curious chamber plants when dwarfed and potted in the Chinese manner. (Hort. Trans. iv. 289.)

CHAP. X.

ORNAMENTAL SHRUBS.

6542. The ornamental shrubs are a much more numerous tribe than the trees; we shall first notice the more select sorts, as the rose, rhododendron, althea, &c. and afterwards, in succession, the deciduous kinds, evergreens, creepers, and sorts for particular purposes.

SECT. I. Select Shrubs.

6543. The term select shrubs we apply to such shrubs as have been much cultivated, and of which numerous varieties are recognised as beautiful.

6544. The rose is known by everybody at first sight, and has been a favorite flower from time immemorial among the civilised nations of Europe and Asia. The shrub varies in size in different species, from one foot to six or eight, and the colors are red, white, yellow, purple, black, striped; simple, or in almost numberless shades and mixtures; and single, semi-double, and double. It is cultivated in every garden, from that...
of the most humble cottager upwards; some species, as R. centifolia damascena, &c. are also cultivated by commercial gardeners on a large scale for distilling rose-water, and for making attar, or essential oil of roses. Six pounds of rose-leaves will impregnate by distillation a gallon of water strongly with their odor; but a hundred pounds afford scarcely half an ounce of attar. The rose is also used in medicine. Botanists are not agreed as to the number of original species of this genus, some regard all the European species as originated from one source; others, and especially the moderns, divide them into species, subspecies, and varieties. The most scientific work which has appeared on the roses in England, is the Rosarium Monographia of Lindley, 1819, in which above a hundred species or sub-species are described, and some of them figured; and Miss Laurence has published ninety plates of A Collection of Roses from Nature, 1810. In France, Guillemeau has published Histoire Naturelle de la Rose, 1800; and Redouté and Thory are engaged in a splendid work, in folio, entitled Les Roses, containing plates of all the known species and varieties of this flower. Thory has published a separate tract on their culture, entitled Prodrôme de la Monographie du Genre Rosier, &c. 1820; Pronville, a Nomenclature Raisonnée, in 818; and Vibert, Observations, &c. in 1820. A copious and intelligent account of the Scotch roses has been lately given by Sabine (Hort. Trans. iv. 231.), and some hundreds of new varieties have flowered from seedling plants, in the nursery of Lee, and will soon be found in his sale-catalogues.

6545. Species and varieties. The lists of the London and Paris nurseries contain upwards of 500 names: that of Calvert and Co., Englishmen, who have established a nursery at Bonne Nouvelle near Bouen, enumerates near 940 sorts. The greater part of these have been raised from seed on the continent, where it ripens better than in this country, within the last thirty years. A number of varieties have also been raised in Britain, especially of the R. spinosissima, or Scotch rose, of which above 500 varieties are procurable in the Glasgow nursery. New varieties are raised in France and Italy annually; Villaresi, royal gardener at Monza, has raised upwards of fifty varieties of Rosa indica; not one of which have, as far as we know, reached this country. Some of them are quite black, others shaped like a ranunculus, and many of them highly odoriferous. The following table contains nearly 150 species and varieties of single roses, of longest standing, arranged according to their time of flowering, heights, and colors; and of the greater number of which there are double and semi-double varieties of the same colors. The names are chiefly taken from Page's Prodrumus, and the plants are known by them in the Hammersmith nursery. Ample lists, as already observed, may be had from all the principal nurseries, and the best mode of making a selection is to view the plants while in flower.

6546.

Propogation. By seed for new varieties, and chiefly by layers for continuing approved sorts. They are often multiplied by budding, cuttings, and suckers.

By seed. Ripen hips contain seeds obtained from semi-double and single flowers, and to increase the chance of new varieties, these should be taken from plants that have been planted among, or near to the sorts of which a cross is desired. We are not aware that Knight's mode of extracting the stamina of the rose has been adopted with the other species of the genus. The cross can be produced from the rose, but there can be no doubt it might be done in many instances. In France and Italy, the usual mode is to form a plantation of double and semi-double sorts mixed indiscriminately, and take the result of promiscuous impregnation. Guilemeaus has given lists of such as are adopted for this purpose; and Villiers, a nurseryman at Paris, speaks of the Rosa indica, as being capable of yielding the sorts of the European roses as he could procure. Austin, nurseryman at Glasgow, and Lee of Hammersmith, mix all the sorts of Scotch roses together in the same plantation. The other mode may be compared to cross-breeding at random; and this to random-in and in-breeding.

Propogation. Most of the hips are ripe before October, but most sorts that come to maturity in this country, will be fit to gather by November. The seeds of the rose require to be one year in the soil before they vegetate; they may either be immediately rubbed or washed, and preserved among sand or cin
der. By the latter method, till late in the following year, when they have been kept, the seed being separated and sown in February, will come up in the May or June following. The best place to lay up the hips is the floor of a cellar, such as that used for storing roots; but in whatever way they are preserved, care must be taken that they are not laid together in such masses as to produce ter
mination; and that the heap be turned over frequently in course of the twelve months, to prevent decay.

The seeds should be sown in a soft moist soil, such as that composed of equal parts of sand and vegetable mould, in a shady situation; it may be covered from a fourth to half an inch, according to the size of the seeds, and the surface should be kept moist by watering in the evenings, till the plants have come up and attained a few inches in height. Erars. In the second spring, they may be transplanted in rows a foot apart every way, and a year afterwards again transplanted to a distance more or less, according to the sorts. Here they are to remain till they flower, which varies in different sorts, from the third to fourth year, or the beginning of the fourth summer. 5550.

By layers. The common mode is to lay down the young shoots of the preceding summer late in autumn, or early in the succeeding spring, and then, with the exception of the moss-rose, and one or two others, they form rooted plants by the next autumn. But it is now found, that if the same shoots are laid down in July, a few exceptions excepted, in the following year, with the seed being separated and sown in February, will come up in the May or June following. The best place to lay up the hips is the floor of a cellar, such as that used for storing roots; but in whatever way they are preserved, care must be taken that they are not laid together in such masses as to produce ter
mination; and that the heap be turned over frequently in course of the twelve months, to prevent decay.

The seeds should be sown in a soft moist soil, such as that composed of equal parts of sand and vegetable mould, in a shady situation; it may be covered from a fourth to half an inch, according to the size of the seeds, and the surface should be kept moist by watering in the evenings, till the plants have come up and attained a few inches in height. Erars. In the second spring, they may be transplanted in rows a foot apart every way, and a year afterwards again transplanted to a distance more or less, according to the sorts. Here they are to remain till they flower, which varies in different sorts, from the third to fourth year, or the beginning of the fourth summer. 5550.

By suckers and dividing the roots. Many of the commoner sorts admit of being rapidly multiplied in this way, and the plants obtained may be planted in their final destination at once.

By cuttings. Most of the sorts might, no doubt, be propagated from cuttings of the young wood, but at a joint where it is beginning to ripen, and planted in sand and vegetable mould under a bell-glass. But this mode is only adopted with such sorts as strike easily, as the R. indica, and other eastern species. 5553. By budding. This mode of propagating roses is adopted chiefly with the rare sorts, and such as are difficult to propagate by layers; for it is found, that plants so originated, even though on stocks of the same species, and raised by any other mode, such as budding in the culture of the rose is to produce standard roses, or to produce several sorts from the same stock. Standard roses are a modern invention, it is generally supposed of the Dutch, first carried to Paris, and about twenty years ago to England. They are highly artificial objects, of great beauty, and some up and attained a few inches in height. Erars. In the second spring, they may be transplanted in rows a foot apart every way, and a year afterwards again transplanted to a distance more or less, according to the sorts. Here they are to remain till they flower, which varies in different sorts, from the third to fourth year, or the beginning of the fourth summer. 5550.

5554. Final situation. No species of rose, wild or cultivated, thrives well in or very near large towns, on account of the smoke and confined air. The yellow and Australian roses (R. lutea and L. bicolor) are difficult to flower in any situation, but seldom or never blow in the suburbs of London: even the monthly rose does not thrive so well there as at some miles' distance in the country. Roses are generally planted in the front of shrubs

5555. Final situation. No species of rose, wild or cultivated, thrives well in or very near large towns, on account of the smoke and confined air. The yellow and Australian roses (R. lutea and L. bicolor) are difficult to flower in any situation, but seldom or never blow in the suburbs of London: even the monthly rose does not thrive so well there as at some miles' distance in the country. Roses are generally planted in the front of shrubs

5556. Final situation. No species of rose, wild or cultivated, thrives well in or very near large towns, on account of the smoke and confined air. The yellow and Australian roses (R. lutea and L. bicolor) are difficult to flower in any situation, but seldom or never blow in the suburbs of London: even the monthly rose does not thrive so well there as at some miles' distance in the country. Roses are generally planted in the front of shrubs

5557. Final situation. No species of rose, wild or cultivated, thrives well in or very near large towns, on account of the smoke and confined air. The yellow and Australian roses (R. lutea and L. bicolor) are difficult to flower in any situation, but seldom or never blow in the suburbs of London: even the monthly rose does not thrive so well there as at some miles' distance in the country. Roses are generally planted in the front of shrubs.
the same basket, they should be as much as possible assimilated in size of leaves and flowers, and habits of growth, and as different as possible in the colors of their flowers. By mixing small-flowered with large showy sorts, the beauty of the former is lost without adding to the effect of the latter.

6555. In roses commonly but one plant of a sort is introduced, and the varieties which most resemble each other are placed together, by which their distinctions are better seen. Particular compartments are often devoted to one species, as the Scotch, Chinese, yellow, burnt-leaved, &c, which has an excellent effect, and becomes a piece of rock-work in the centre is covered with the creeping roses, and on other occasions these are trained to trellis-work, which forms a fence or hedge of roses round the whole. In this hedge, standard-roses are sometimes introduced at regular distances; a grove of standards is also frequently formed in the centre of the rosary, and sometimes they are introduced here and there in the hedges.

6556. Standard roses, however, have certainly the best effect in flower-borders, or when completely detached on a lawn: their sameness of form, and that form being compact and lumpish, prevents them from grouping well, either among themselves or with other objects. Their beauty consists in their singularity as rose-plants, and in their flowers, and, therefore, to display these beauties to the best advantage, they require to be seen singly, or in succession. This is the case where they occur as single objects on a lawn, or in the centre in, and here and there among, groups of flowers; or in lines or avenues, along flower-walks. In the gardens of the Grand Trianon, they are planted profusely in large masses, like plantations of trees and shrubs, and there much of their individual beauty is lost, and no good general effect produced.

6557. Soil. Most species of the rose in their wild state grow in sandy and rather poor soil, excepting such as are natives of woods, where the soil is richer, and comparatively moist. But all the cultivated roses, and especially the double-flowering kinds, require a rich loamy soil, inclining to clay rather than sand; and they require also, like most double flowers, plenty of moisture when in a growing state.

6558. General culture. To produce strong flowers, roses require some attention to pruning; old wood should be yearly cut out, and the young shoots thinned and shortened according to their strength, and whether number or magnitude of flowers be wanted. Those sorts which throw up numerous suckers should be taken up every three or four years, reduced and replanted; and most sorts, excepting the standards, will be improved by the practice, provided attention be paid to remove a part of the old soil, and replace it by new. The points of the shoots of the more delicate sorts of roses are very apt to die when pruning is performed in winter or spring; to avoid the consequences of this evil, many give a second pruning in June, or do not prune the tender sorts at all till the beginning of that month. A very good time for performing the operation is immediately after the bloom is over; cutting out old exhausted wood, shortening shoots which have flowered to a good bud accompanied with a healthy leaf, but leaving such shoots as are still in a growing state untouched till October. Where very large roses are wanted, all the buds but that on the extreme point of each shoot should be pinched off as soon as they make their appearance, and the plant liberally supplied with water. To lessen evaporation, and keep up a constant moisture at the roots of their roses, the Paris gardeners generally mulch them with half-rotten stable-dung, or partially rotten leaves.

6559. Forwards and retarding roses. The earliest flowering rose is the monthly, which, in mild seasons, and planted against a wall, will sometimes flower in the beginning of April; the roses next in succession are the cinnamon, which flowers in May; the damask, in the end of May or beginning of June; the blush, York and Lancaster, Provence and Dutch hundred-leaved, in June, July, and August. The Virginia and musk roses are the latest European sorts; they flower in September, and in shaded situations will sometimes continue in bloom till the middle of October; but the earliest rose (the monthly) is also the latest, and generally continues flowering till interrupted by frost. The earliest sorts may be materially forwarded by being planted against a south wall, and if portable sashes are placed before them, and the wall is either flued and heated by fires, or a lining of dung placed behind, the plants may be brought to flower in February or March. The monthly rose being protected by glass in autumn, or aided by artificial heat, may be continued in bloom till Christmas. A very common mode of obtaining late roses, and one of the greatest antiquity (48), is by cutting all the flower-shoots off when the buds begin to appear, or by rubbing off all the rudiments of shoots, of every kind, early in spring; a second crop is in consequence produced, which will not be in a state to bloom before the autumn.

6560. Forcing the rose. The best sorts for this purpose are the common and moss Provence; the Indian sorts force well, or rather, in stoves, continue in bloom all the year; but the commoner varieties of these not being fragrant, they are in less repute than the European roses. Rose-plants should be a year in pots previously to the autumn when it is intended to force them; they should be planted in pots of six or eight inches' diameter, in rich loam, and plunged in an open airy situation; their flower-buds pinched off as they appear; and the plants put early into a state of rest, by excluding the sun and rain, but
not a free circulation of air. Abercrombie says, "There is no certainty of attaining a fine blow of roses in the depth of winter by the most expensive artifices of forcing; and yet fine flowers may be produced early in the spring by any ordinary stove put in operation in December. When the plants are first introduced, keep the air of the house at about 50°, never letting it fluctuate to more than two or three degrees below or above. In the second week, aim at 60° as the standard; in the third week at 65°. When a month has nearly elapsed, begin to increase the heat gradually to 70°; having brought it to this standard, let it afterwards exceed it from three to five degrees, rather than sink below. A succession may be kept up by introducing some pots every eight or ten days."

6561. Insects. All the species of roses are very liable to the attacks of insects, especially of the aphides; some, and especially the briar and Scotch rose, are attacked by the Cynips roseæ, which, by puncturing the leaves, occasions the production of rose-galls, and of those mossy tufts often seen on wild roses, which were formerly considered as fungi and used in medicine. A great number of insects seem fond of the flowers of roses, from the appalling earwig (Forficula auricularia) to the seemingly harmless lady-bird (Coccinella 14-guttata) (fig. 621), which deposits its larvæ (a) in the leaves of various species, both wild and cultivated. There seems no remedy for these pests, except to follow them as they get out of the pots, or into other places, or part of the shoot which is infected by them. Under cover, tobacco-smoke will prove an effectual remedy for the aphides; but the larvæ of many others, and especially of tipula and the teat-thrips, which occasion the wrapping up and shrivelling of the leaves, can only be removed by washing with lime-water or hand-picking.

**SUBSET. 2. Select American and other Peat-Earth Shrubs, viz. of Magnoliaceæ, Magnolia; of Rhodoracææ, Rhododendron, Azalea, Kalmia; of the genera Cistus, Arborua, Vaccinium, Andromeda, Erica, Daphne, and various others.**

6562. Of select American shrubs there are numerous species and varieties, both decided and evergreen, which will be found arranged according to their heights and colors in the two succeeding tables, and those requiring a peat-soil distinguished by a letter (p). They are all highly valued for their flowers, which are large and magnificent in magnolia and rhododendron; odoriferous in azalea and daphne; and beautiful in andromeda, vaccinium, and erica: arbustus is valued both for its flowers and fruit. They are mostly natives of America, and introduced within the latter half of the last century.

6563. Propagation. They are all propagated by seed or by layers; though grafting or inarching is resorted to in some cases as more expeditious. The seed is either procured from America, or saved in this country, and, being very small, is sown as early as possible in pans of peat-earth, and placed in the shade. In winter it is placed under a cold-frame, or otherwise protected from the frost, and the plants come into flower in the following year. The plants are generally set out in peat pots, or into other pots, or into beds of peat-earth in a shady situation. Here they are protected by hoops and mats during winter; and in two years are again transplanted into a similar soil and situation, and at distances corresponding to the size of the leaves, or habits of the plants; here they remain till they flower, or till wanted to be removed to their final destination. They commonly flower from the fourth to the seventh year.

6564. By layers. The young shoots only are used for this purpose, either laid down in June and July in full growth, or in the following autumn; by the former plan a year is gained, as the shoots will be rooted, and may be removed by the succeeding winter or spring. Some sorts of magnolia, rhododendron, &c. require two years to form a sufficient number of roots. The plants, when removed, may be planted in nursery lines, in proper soil, and kept well watered during summer, and protected the first winter by mats; or, they may be planted in pots, and receive, during winter, the protection of a frame.

6565. By cuttings. Of most of these kinds, occasional, though but rarely, may be resorted to. Some species of azalea and andromeda throw up numerous suckers, and the heaths may often be increased by dividing their roots. 6565. By cuttings. Some of the azaleas, heaths, &c. may be multiplied by cuttings of the young shoots, when lannated; or when the wood is beginning to ripen, and planted in pots or pans, covered with a hand-glass. If this operation is performed in the end of June, they will be ready to remove into prepared beds, or to plant in small pots by the middle of September.

6566. By grafting or budding onarching. The se is practiced with the sorts of magnolia, arbustus, daphne, &c. which are placed on stocks of hardier species of the same genus, as on M. purpurea, M. unedo, D. laureola, &c. The stocks are planted in pots a year before wanted, which admits of their being placed in any position with respect to the shoot being inarched. The daphnes and arbustus and arnudache, are generally grafted with detached scions.

6568. Culture. The culture requisite for American plants, Abercrombie observes, "principally consists in providing some imitation of the original soil, in order that they may flourish in full vigor; and, where there is no factitious soil provided, in making a compensation during the dry part of summer, by plentiful waterings. Most of the exotic shrubs brought from America, were originally found growing on tracts of ground resembling our beds of peat, except that the alluvial soil there extends along a greater surface, and the body of vegetable mould embedded in the swamp is richer and deeper, being on a scale corresponding with the magnitude of the rivers. The native plants found in these situations, vegetate with the highest vigor and luxuriance. The soil in many parts is so pervaded by vegetable substances, that where from any cause a section of the solid ground occurs, as in the bank of a river, or the shaft of a well, a layer of decayed logs, branches, and leaves of trees is uncovered to the spectator. The luxuriance of the vegetables may, however, partly be ascribed to the excessive moisture which is peculiar to the climate of America. In a few places, indeed, on the western coast, rain is not known; but the soil there is, in general, copiously watered by dew, so as to render it highly productive. In the season called winter by the natives of South America, lasting from May to November, a continued succession of impetuous rains gives to the plains, in most places, the appearance of an ocean. When the rains have ceased, the humidity
of the climate is kept up by a constant evaporation from swamps, rivers, and lakes, the largest in the world. As we cannot have the mitigated warmth of the climate of South America in plantations, in the full ground, and as the temperature of our winter cannot be expected to coincide in its effects with the corresponding season even of North America, when so many local circumstances are different, it is neither indispensable, nor perhaps advisable, to create an artificial swamp for the cultivation of many American plants. It is mostly safer to confine the efforts of imitation to the kind of earth, unless the water can be carried off at any time; for the lodgment of wet might cause some kinds of roots to perish in cold weather. Thus the andromeda arborea would be injured by being floated in winter, and must be protected from frost, though it requires a deal of water in summer. The great object is to imitate the American peat. This is a composition of the branches, twigs, leaves, and roots of trees, with small plants, grass, and weeds; by having lain immemorially in water, the whole is formed into a soft mass, and, when the materials are completely decayed and blended so as to be homogeneous in appearance, the compound is the finest vegetable mould: where this description of peat cannot be obtained, recourse must be had to the best that can be procured from marshes, bogs, or healthy commons, which must be well turned and sweetened, and mixed with sand and rotten leaves or dung." The soil being procured, the next thing to be done is to form a stratum of it of sufficient thickness in the site intended for the plants. When they are merely to remain a year or two, this need not be above a foot in depth; but where they are to remain permanently, it should be at least three feet thick. To encourage the roots to penetrate the native soil, the bottom of the excavation should be dug and mixed with peat; unless a bottom of rough gravel were substituted at the depth of four feet, and such an arrangement made, as that water could be introduced to, and withdrawn from, this layer of gravel at pleasure, so as to saturate the whole superstratum of peat. In level situations, and where water was abundant, this plan might be readily adopted, and none could more closely imitate nature, as, by keeping the surface of the peat a few inches below the level of the natural ground, the water might be allowed to rise a few inches above the peat, and inundate the whole surface of the American ground. In peat countries, and where the climate is moist, as in Lancashire and Cheshire, admirable contrivances of this kind might be adopted, and the American and bog-earth plants, herbaceous as well as shrubby, grown to the greatest perfection.

6560. Final situation. American and peat-earth shrubs, requiring large masses of their peculiar soil, and frequent artificial waterings, cannot conveniently be introduced in mingled borders or shrubberies. They are therefore generally planted by themselves in beds or compartments of peat-earth; or entire gardens or shrubberies are devoted exclusively to them. This last mode appears decidedly the best, as the general habits and appearance of American peat-earth plants, independently of their culture, do not harmonise remarkably well with European species. An American garden may have a northern or eastern exposure, and if it slopes considerably will be still less affected by the warm dry weather of summer. It may be laid out in any of the different styles of flower-garden (figs. 541. to 545.); herbaceous plants introduced as well as shrubs, and the whole surrounded by a sloping phalanx of American trees. The sorts may either be arranged in the mingled manner (6139.), or grouped or classed according to some system, (6141. to 6150.) Many and indeed most of the American shrubs thrive under the partial shade of lofty deciduous trees, and the leaves which fall from these protect their roots both from the frosts of winter and the drought of summer, while they constantly decay into vegetable mould, and thus at the same time afford a supply of nourishment. Hence, in some cases, the hardier sorts of rhododendron, azalea, andromeda, &c. may be introduced as undergrowths in the margins of thin woods, placing under each plant a cubic yard or more of its proper soil. This mode of planting, it would appear (Mason on Design, art. Pitt), was first adopted by the great Earl of Chatham; but it has been carried to the greatest extent, not only with American plants, but with roses and other tender shrubs, in the extensive woods of Fonthill, where, as also at King's Weston near Bristol, Kenwood at Hampstead, &c. many of the plants shed their seeds, and young rhododendrons and azaleas spring up in abundance. In the nurseries, it is a general practice to keep American and other peat-earth plants in pots, and to protect them during winter in frames and pits for convenience of deportation. At the Hammersmith nursery, one green-house is exclusively devoted to evergreen magnolias. All the American and peat-earth shrubs may be selected from the three first tables in next section, by observing the indication of peat-soil (letter p); and the herbaceous peat-earth plants may be selected from the tables of Border-Flowers in a similar manner.

657a. The propagation and culture of shrubs being the same as that for trees, we combine both subjects in the catalogue of arboriculture in the succeeding book.

### Sect. III. Selections of Shrubs for particular Purposes.

6575. The particular purposes to which shrubs, like flowers, may be applied, are the concealment of deformities or imperfections, and the production of particular beauties or desirable effects. We shall here select the names of a few for concealing vertical and horizontal deformity; for producing an immediate effect as to bulk; for producing vegetation under the shade and drip of trees; for ornamenting water and rocks; for forming edges and hedges; for diffusing agreeable odors; for being ornamental by their fruit; and for economical or botanical purposes.

#### Subsect. 1. Shrubs for concealing vertical and horizontal Deformities.

6576. **Vertical deformities** may either be concealed by the rapid and tall growing sorts (Subsect. 2), or by the climbers or twiners, either deciduous or evergreen. The climbers may be trained to a trellis, arbor, or fence, or tied to a trellis, or allowed to climb on branches and spray; for the twiners, tall sticks or poles are necessary.

#### Subsect. 2. Shrubs of rapid and bulky Growth.

6576. **Shrubs of rapid and bulky growth** are often desirable to produce immediate effect in laying out pleasure-grounds, as well as for producing shelter, and concealing objects.

#### Subsect. 3. Shrubs which thrive under the Shade and Drip of Trees.

6579. **Shrubs which grow under the shade of trees** are found in practice to be a most valuable class for filling up blanks in old shrubberies, or stock plantations; and thus producing greenness, variety, and a healthy aspect, instead of emptiness, haggard stems of trees, or mere ghosts of plants.

---

**Note:** The text is a catalog of shrubs, categorized by height and season (July and August). Each section provides specific plant names and their uses, such as concealing deformities, providing immediate effect, and growing under shade. The text emphasizes the diversity of uses for these plants, from ornamental to practical purposes.
SUBSEC. 4. Shrubs for planting by the Sides of Pieces of Water, or in Marshy Grounds, and among Rocks.

6589. Besides aquatic shrubs, most of the peat-earth species are also suitable for planting in marshy situations.

Deciduous. Alnus pumila, Betula nana, punila, and sibirica, Bica palustris, Myrica cerifera, and galea, Salix, most of the species.

6581. Of mountain or rock shrubs the following are some of the most hardy: —

Deciduous. Atrophaxis alpina, Daphne alpina, Genista decumbens, Lonicera alpigena, Oenosis fruticosa, Potentilla fruticosa, Rhamnus azalea, Rham- 

dodendron daucum, Ribes alpinum, trum nigrum, Erica, all the hardy species, 

Rosa alpina, spinosissima, Rubus can- 

sucus, Euonymus, spindle, Spiraea, Spartium 

japonicus, Juniperus communis, Ros- 

marinus officinalis, Lecanora vulgaris, 

Taxus baccata, Thuya occidentalis, 

Taxis baccata, Thuya occidentalis, and 

Ligustrum vulgare, Forsythia, Spiraea, 

Viburnum tinus, Prunus lau- 

rorosaeus.

SUBSEC. 5. Shrubs for forming Edgings and Hedges in Gardens.

6589. Of shrubs for edgings few are comparable to the box (Buxus sempervirens var. nana); but some others may be occasionally used, as the

Andromedia polilolia, Arbutus alpina and 

viscum, Emertum nigrum, va- 

tetrax, vulgaris (Califina, W.), Laven- 

dula spica, Sedum buxifolium, and even 

Ulex nana.

6583. Hedge plants. The following are a few of the numerous plants which may be used as hedges for shelter in gardens; almost all the free-growing sorts may be planted in rows, and cut in the hedge form; but the following sorts will form compact evergreen shelters:

Buxus sempervirens, Juniperus com-

nus, Ulex europaeus var. hibernicus, 

Ilex aquilinum, Larascoldis, Ligus-

trum vulgare, sempervirens, Olea (Wild), 

angustifolia, latifolia, and media, Kham-

nus alternus, Rosmarinus officinalis, 

Taxus baccata, Thuja occidentalis and 

orientalis, Viburnum tinus, Prunus lau-

rorosaeus.

The creeping shrubs may be formed into hedges by training on frame-work.

6584. Flowering hedges may be formed of the following deciduous sorts: —

Rosa varius species, Cornilia emer-

us, Daphne mezeceum, Hibiscus syriacus,

Philadelphia coronarius, Prunus japonica, 

Robinia hispida, Sparreria multiflorus, 

Spirea hypericiolida, Syringa persica, 

vulgaris, Hydrangea, or vario, &c.

SUBSEC. 6. Shrubs whose Flowers or Leaves have volatile Odors, and diffuse them in the surrounding Air.

6585. Of shrubs whose odors are volatile only a few have this quality in the leaves as well as the flower; these are marked by: —

Deciduous. Azalea most of the species, 

Rubus arcticus, Daphne me-

zeceum, Rosa rubiginosa, iow., 

Salix most of the species, but espe- 

cially S. viminalis, alba, Syringa vul-

garis, Prunus laevis, Rosea officinalis, 

Climbers. Clematis flammula, Jasminum officinalis, Lonicera caprifolii, peri-

ctlymenum.

SUBSEC. 7. Shrubs or their Fruit as well as Flowers.

6586. Ornamental fruit-bearing shrubs are also serviceable as encouraging singing-birds to resort to the shrubbery.

Deciduous. Berberis vulgaris, Ligustrum vulgare, Ribes alpinum, cynosbat, Rosa spinosissima, et villosa, Sorbus aucuparia, Rhamnus cathartica, most of the species of Viscum, Lonicera alpina, Viscum, and all the species of Cornus, Euonymus, Mespilus, Prunus, Pyrus, and Sonchus among herbs more ornamental than the scone (Prunus spinosa, Linn.); it is profusely covered with odoriferous white flowers early in April, and with dark purple fruit with a fine bloom, from September to October. It is much cultivated in Japan (1644), where its flowers attain the size of a double rose.

Evergreen. Lavandula spica, Rosma-

rinus officinalis.

Climbers. Clematis flammula, Jasminum officinalis, Lonicera caprifolii, periy- 

clymenum.

SUBSEC. 8. Selections of Shrubs for botanical or economical Purposes, parasitic Trees, and Shrubs for a small Shrubby.

6587. Selections of shrubs may be arranged in innumerable modes, as well as herba- 

ceous plants; as, according to soil, climate, habitation, country, rarity, place in botan- 

cal systems, uses in agriculture, or the arts, &c. No gardener can make any selec- 

tion who does not know by inspection the actual plants, and their habits, culture, and 

history; to him it is needless to repeat the sources to which he may have recourse for 

forming any classification whatever.

6588. A selection for botanical purposes will necessarily include parasitic plants, of which the only hardy genus is eucalyptus. This is propagated in February by sticking the berries, which are viscid when bruised, in a slit like that made in budding, on the smooth bark of the apple, pear, thorn, or almost any tree. If these are not washed away by rain, or otherwise rubbed off, they will germinate in the following sum- 

mer. To make sure of their not falling off, some bore a hole in the bark and insert the seed; or cut a notch in it, and make a slit: the last seems the best mode, and has been successfully adopted by Professor Thouin in the Paris garden, and extensively by Watts, a nurseryman at Acton, on most sorts of trees. Some, as Professor Walker (Essays on Nat. Hist.), on the supposition that the will not vegetate till they have passed through the stomach of a bird, recommend causing fowls to eat the seeds, and then swallowing them. It is found not to be necessary, for the digestive juice of the stomach do not destroy the vegetative power of seeds which pass rapidly through it, yet in most cases it does. The mistle- 

toe in nature is propagated by the mistletoe-thrush (Turdus viscivorus), but not, as is generally supposed, by means of its excrement. This bird feeds on the berries of the mistletoe in winter. These, from their viscosity, often stick to the outer part of the bird's beak, and to disengage them he strikes it against the branch of the tree on which he alights, and leaves the seed sticking to the bark; if this should chance to be a smooth part, the seed will adhere to it, and the succeeding spring will grow, the radicle piercing the bark, and the plume unfolding itself in the air. The vacuum grows best on the pyrus and malus tribes, but it will also grow on the ash, poplar, lino, oak, fir, &c., on which trees we have observed it in abundance in Germany. In the pine-forests, near Magdebourg, it is most abundant on pinus sylvestris.
6589. \textit{A selection of trees and shrubs of great beauty and easy culture}, proper for introduction in shrubberies of limited size: —

Deciduous trees. \textit{Acer pensylvanicum}, \textit{Crataegus} 

\begin{itemize}
  \item \textit{Eucalypthus communis}, \textit{Cupressus} \textit{disticha}, \textit{Picea} \textit{sylvestris}, \textit{P.} \textit{pungens}, \textit{P.} \textit{pseud-scaica}, \textit{Sorbus} \textit{aucuparia}, \textit{Tilia} \textit{europaea}.
\end{itemize}

Chap. XI.

Frame Exotics.

6590. \textit{Frame exotics} are such plants as are rather harder than those kept in the greenhouse and of low growth. Some of those enumerated here will also be found among the hardy plants. The frames or pits in which they are kept are never artificially heated, but are well covered with mats or other materials during severe frost. The frames are sometimes attached to the front of the green-house or stove, and thus derive some heat from the front flue, which, when an outside frame in contemplation, is generally built in the front wall. When this is not the case, they may be advantageously placed on a border sloping to the east, south, or west, under the shelter of a hedge or wall. The pots should be plunged in scorie, ashes, sawdust, or any similar non-conductors, and abundance of air, and little water given in the winter time. Few scenes are more interesting in the spring season than a small oblong flower-garden, surrounded by a holly-hedge enriched with many spikes of coral berries: within the hedge a sloping frame-border all round; on the north side, containing frame exotics; on the west, early-flowering bulbs, as hyacinth, crocus, narcissus, &c.; on the east, choice auriculas; and on the south side (the border facing the north), a collection of alpines. The middle of the garden laid out in beds of florists' flowers. In summer the sashes are applied to various useful purposes, as to ripen fruits against walls, to raise late crops of cucumbers, melons, &c.

Sect. I. Frame Woody Plants.

Those marked cl are climbers; tw are twiners; and tr are trailers.

*The propagation and culture of frame exotics is the same as for green-house plants.*
6597. Of green-house plants we shall first arrange some of the more select tribes, and next class the most showy and easily-flowered sorts, under the head of woody, succulent, climbing, herbaceous, bulbs, annuals, and biennials. Each of these subdivisions will be arranged as before as respects time of flowering and color; but considering the limited height which all exotic plants attain in pots, it has been considered unnecessary to attend to size. Such as are trees in their native country will be indicated by the letters tr, and also such as are biennials by the letter b, the most tender, most showy, and those continuing in flower two or three months 3, as before.

Sect. I. Select Green-house Plants.

6598. As select green-house plants we shall consider the geraniums, heaths, and camellias; which three tribes united will supply a green-house with flowers of almost all colors, during every month of the year.

6599. The gerania tribe comprehends numerous species and varieties of herbaceous suffruticoses and shrubbery plants, generally of a somewhat succulent nature throughout. They are almost all natives of the Cape of Good Hope, and with the exception of three or four species, have been introduced, or originated here from seed, during the present and latter end of the last century. They are chiefly admired for their flowers, which they produce in abundance from May to September, generally in corymbs from the axil of the leaves, of every shade of red, scarlet, and purple, mixed with white and yellow. The plants are easily cultivated, and by proper pruning, with the aid of gentle forcing in winter, many of the species, as the P. zonale, cuculatum, cordatum, &c. may be kept in flower all the year. The best collection of this family is in the nursery of Messrs. Colville, under the care of the botanist Sweet, whose Gerania, now publishing, is the most elegant and complete work of its kind.

6600. Species and varieties. Many species and subspecies have been received from the Cape; but the greater number of the admired sorts have been raised in this country from seed; some of these have received systematic appellations, but the greater number have been named by those who raised them after themselves, or their friends, in the manner of florists' flowers. The following table contains some of the old established sorts, arranged according to their habits of growth and time of flowering; the flowers of most of the sorts are so mixed in regard to color, that it is almost impossible to class them in that respect; most of them are variegated with red, purple, scarlet, and white.

6601. GERANIÆ.
being covered with a glass. Cuttings of the roots of such sorts, as P. triste, gibbosum, &c., strike readily; a small portion of the root being left above ground. The fibrous-rooted herbaceous sorts, as E. Chama-
droideis and glandulosum, may be multiplied by dividing the roots. "From the latter end of March to the middle or end of July," Cushing observes, "cuttings of all the common kinds of geranium may be put in with success: Let a moderate hot bed be made up, and bedded with some old tan; when it is of a proper temperature, let the cuttings be made, and put in some nice rich loam; plunge the pots to the rim on the bed, and shade them for a day or two, but no longer. Pick off any damping leaves that may appear, water them occasionally, and observe to put them in shade in the sun. As the plant produces its stout plants by the end of autumn: the more curious kinds are in general done by cuttings of the thick fleshy roots, which they produce in abundance: as many of these as can be spared with safety being taken off carefully from each plant, and a few of the finer fibres attached to them and neatly potted in small pots, leaving the crown of each plant one fourth of an inch over the surface, watered and set on a moderate heat, will, in a few weeks, make excellent plants: one, two, or more stems, which they in general pro-
duce, being left to form the plant." (Exotic Gard. 90.)

6604. Forcing the geranium. The hardier shrubby sorts force well with a very gentle heat, and in this way may be kept in flower during the winter months till April and May, when they will be succeeded by those that have been kept in the common greenhouse temperature.

6605. The heath family constitute an extensive assemblage of low shrub herbaceous plants, much valued for the beauty of their flowers, and the blossoming of many of them in the winter season. Scarcely any exotic heaths were known in Miller's time, and none of the Cape species. Almost the whole of these have been introduced to Europe during the reign of Geo. III., and the greater part by Masson, a collector, who made two voyages to Africa at that King's expense.

6606. Species and varieties. Above 300 species have been introduced, some of which, from the difficulty of propagation, or accidental causes, have been lost; but there are still upwards of 250 sorts, which may be propagated from the nursery. There are also several sorts which have been raised from seed. The Hon. and Rev. W. Herbert has raised several hybrid heaths, which gives reason (Hort. Trans. iv. 27.) for thinking that many of the sorts imported from the Cape, and considered as species, are only hybrids pro-
duced by promiscuous copulation. These species have here arranged most of the sorts procurable in the nur-
sery, and, in addition to the time of flowering, height in inches, and color, designated the form of the flower, as bell (b), pill or tube shaped (p), open (o), roundish (r), or ventricose (v).

**ERICA.—AUGUST.**
909

6608. Propagation. A number of the sorts ripen their seeds in this country, and may be so propagated; but the greater number are struck from cuttings, and some few, as E. massoni, retorta, petiolaris, &c., by layers, which require two years to throw out roots. The seeds are often imported from the Cape, and are usually sown in the spring, or sometimes in the autumn, in a frame of peat and sand, very thinly covered, placed in the shade, and bell-glasses placed over them. The soil must be kept moderately moist by gentle waterings: they will in general come up in six weeks or three months, and the plants may then be pricked out into small pots, or be put to the open air, or in, string for potting in a good watering, in the ring of the pot, and place them in the shade on a spent hot-bed, keeping them close till rooted, which, with the free sorts, take place in about two months: when rooted, which is known by their shooting, take off the small glass, for about a week, at night, previous to its total removal. They will be fit to pot off in March the ensuing year.

6609. Henderson of Woodhall's mode of striking ericis is as follows:—" The month of July is a good time for putting in most of these cuttings; but the cuttings must not be taken off till the young wood be firm. Cutting off the young wood in the wood is a very bad state. I have plants of about three quarters of an inch long, pulling them off downwards; strip off the leaves nearly half the length of the cuttings; place the cutting on the nail of the thumb, and, with a sharp knife, at right angles, cut off the small end close to the joint, or place where it was pulled off the plant. Having done this, plant them in the river sand, placed in a frame, put in the sand, without injuring the shoot; this is rather a nice operation, and should be done with a sharp penknife, for the least bruise spoils the cutting. Dibble them into a pot, filled with moistened common white house-sand, before they have time to flag; when they are all planted, water the whole to fix them. I have plants of about twelve inches, in a small pot, 6 cm. or 8 cm. in diameter, put in the frame, with the rim of the pot, and placed them in the shade on a spent hot-bed, keeping them close till rooted, which, with the free sorts, take place in about two months: when rooted, which is known by their shooting, take off the small glass, for about a week, at night, previous to its total removal. They will be fit to pot off in March the ensuing year."

6610. Culture. "A prejudice," Page observes, "having spread that the culture of these plants is difficult, one of the greatest ornaments of the green-house has hitherto, of late, been neglected; although the mode of culture is as easy, and nearly as certain, as that of the geranium, but requires a little more delicacy in the execution. The soil for all the species is peat-earth mixed with one sixth to one fourth of fine white sand. The pots should be well drained and rather small; but large, in proportion to the size of the plants. Healths best in a house by themselves, and placed as close to the glass as possible, without risk from frost: they do not require so much heat as most green-house plants, but abundance of air, and, above all, great regularity as to water, so as to preserve, as much as possible, an equable and moderate degree of moisture about their roots. The mass of mould being once thoroughly dry, the plant is more susceptible of cold and operation than with less rest. In the pots the top of the pot is kept in a pan of water. No kind of plant is more injured by being kept in a chamber than heath, nor will they thrive in a green-house or in the open air, within the influence of the smoke of large towns. In the best situations and under the best management, many of the species are short-lived, and therefore require to be propagated frequently."

6611. The ericas are not subject to insects. Henderson says, "I have never had any insect on them except the green fly. The old grandiflora is the only one with me that has been attacked. I destroyed the flies by dipping the plants into an infusion of tobacco smoke. The ericas, I find, do not agree well with being smoked with tobacco-paper in the usual way." (Ib. l. 327.)

6612. Of the camellia genus there are four species introduced: the C. bohea, viridis, and sasanqua, and C. japonica, introduced in 1759, is a ornamental evergreen shrub, which grows to the size of a low tree in China, with dark-green ovate leaves, on short petioles, and flowers red, white, striped, and variegated, and single, semi-double, and double, without fragrance, but of great splendor in beauty, and peculiarly valuable, as appearing in December, January, and February.

6613. Varieties. These are —

6614. Propagation. The single red camellia is propagated by cuttings, layers, and seeds, for stocks; and on account of its ornamental value, it is sometimes advanced by budding or grafting with the white camellia. The red camellia is frequently propagated by cuttings of ripened shoots of the preceding summer, which are taken off in August, cut smoothly across at a joint or bud, or two or three of the lower leaves only taken off, and the cuttings then planted and made firm with a small quantity of sand. The cuttings may be left in aspirators, soil, or sand alone. The pans are cut into a pit or cold-frame, without being covered with glasses, but shaded during the first few days, and should be cut into in the following spring such as are struck will begin to push, when they are to be placed in a gentle heat. In September or October following, the rooted plants will be fit to pot off; and in the second or third spring, before the leaves are five or six inches long, in earth, which, when they are making young wood. He puts fifty cuttings in a pot of sand eight inches in diameter, sets them in a cool place in the back of a vinery or peach-house for a month or six weeks, and then puts them.
them to the brim in a hot-bed where there is a little bottom heat. A speedy mode of obtaining stocks is by planting stools in a pit devoted to that purpose, and *laging* these in autumn; the following autumn now roots have developed, they are transplanted to the nursery, when, when the first warm days of the succeeding spring. Inarching or grafting is performed early in spring, when the plants begin to grow; the chief care requisite is so to place and fix the pot containing the stock, as that it may not be disturbed during the process of connexion with the scion. The graft being clayed over, is then covered with moss, to prevent evaporation. Inarching and independent grafting is called side grafting (393); it is generally used, in the case of orange-trees (3910); but the operation of tonguing is generally omitted, as weakening the stock, and unnecessary, with a view to prevent the scion from being blown off by the wind.

Walls are sometimes removed from the single warmhouse; these require two years to come up, but make the best stocks of any. The tea-camellias are generally propagated by layers, but will also succeed by cuttings.

6615. Soil. Some cultivators grow the camellias chiefly in peat; Messrs. Loddiges, who have the most successful, say that they used, formerly of this purpose, three separate kinds of peat; and they are in a similar soil in the Hammershmit nursery. Of late, Messrs. Loddiges find light loam alone to answer as well or better. In the Count de Vande’s garden, at Bayswater, rotten dung is mixed with loam and peat, and the surface of the pots are top-dressed with fresh cow-dung, free from little cockles. No manure is to be used which is not most luxuriant; the most splendid camellias are grown in loam and peat. Henderson, of Woodhall, is one of the most successful growers of the camellia in Scotland; his compost is as follows: Take one part of light-brown mould, one part of river-sand, one part of peat-earth, one half part rotted leaves. Mix them all well together, and when the camellias require shifting, put some broken coal-char in the bottom of the pots, and some dry moss or hyssop over it. (Caled. Mem. iii. 316.)

6616. Camellia-house. Camellias have the best effect, and are most grown to advantage in a house entirely devoted to them. Such a house should be rather lofty, as the plants never look so well when six or eight feet high, trained in a conic form, and clothed with branches from the root upwards. The plants should be raised near to the glass by means of a stage, which should be so contrived that as in height, it may be lowered in proportion. Only the very best crown or patent glass should be used; because, in the first, the inner surface is inclined, and on this at least one side, generally, on the whole six or seven layers of the sun's rays, as to concentrate them, and burn or produce blotches on the leaves of the plants. Every cultivator must have observed that leathery shining leaves, like those of the orange, myrtle, &c., are more susceptible to this solar heat than others; but the solar radiations in the greenhouse are rendered less penetrative by the glass, and the glassmen recommend a roof which will not admit much light; others, the use of green glass; of an opaque roof, with glass in front only; or, of a house facing the north. Our opinion is, that a light house facing the south, or, better still, glass on all sides, is essential to the perfect growth of the plants; and that all solar reflections may be avoided, or at least rendered of no consequence, by using the best glass, and placing the plants as near it as possible.

6617. To grow the camellia to a high degree of perfection, considerable care is requisite. The roots are very apt to get matted in the pot, and by the space they occupy, so to compress the ball of mould as after a time to render it impermeable by water. Hence frequently water is poured on the pots, moistens all the earth, and does not escape by the sides of the pot, moistening only the surface of the fibres. The same cause renders examining the roots, and shifting or reducing and replanting them, a very insidious operation. When the plants require to be liberally watered, and also a degree of heat somewhat more than is usually given to green-house plants. If this heat is not given in November and December, the plants will not expand their blossoms freely; and if both water and heat are not regularly applied after the blossoming season, vigorous shoots will arise. To form high shoots on their present plants, the plants must have been pruned so as to make them throw out side branches from every part of the stem: to encourage these, the plants should not be set close together on the stage. In summer they may either be set out of doors on a stratum of scoriæ, or on a pavement, in a sheltered but open situation; or the glass may be taken off. The harrier sorts, as the double rose should be potted, flowers, &c., are very well when planted in the bed or border of a conservatory, provided the roof or entire superstructure can be removed in summer to admit the full influence of the weather. Where this cannot be done, the camellia and most other plants are not likely to thrive. The best season for planting, whether of the whole plant or of the extreme branches, is the middle of the year, both of which have the advantage of the heat, air, or in a greater degree of heat at pleasure. The single and double red camellia will endure the open air, when trained against a south wall, and protected by mats in winter; and there can be no doubt that in time these and other species will be more perfectly inured to our climate.

Woodhall, (Caled. Mem. iii. 316.) follows another plan of treating the camellias. "The best time for a regular shifting of the camellias is the month of February or beginning of March. After shifting all those that require it, put them into the peach-house or vinery, where there is a little heat; if there be no peach-house, vinery, nor pinery, set them in the warmest part of the green-house. They will continue during the whole winter in the same state, till February, when they have finished their growth, give them plenty of water. They may be kept in the vinery or peach-house till they have formed their flower-buds at the extremity and sides of the young growths, when a few of them may be removed in a colder place, say a gold-room, for the camellias are fond of being shaded during strong sunshine. In three or four weeks after, a few more of the camellias may be brought from the vinery or peach-house, and put into a cooler situation. This may be repeated three or four times, which will make as many different successions of flowering. Those that are wanted to come into flower early, may remain in the warm house till they are beginning to flower, when they should be taken to a cold place, say the coldest place of the green-house; then give them plenty of light only, and they will open their flowers well, and stand long. A camellia cannot stand heat when in flower, indeed they seldom open their flowers fine when in heat, and, at all events, the flowers will soon drop. A good rule is, that all the very young camellias should be put into the first or middle of October, and a pretty large plant, having perhaps fifty or a hundred flower-buds, will continue in flower till the month of January. Those plants that are removed early from the vinery, will most certainly succeed in this, and were the very young camellias. These last should be immediately taken into the heat. They will make their young wood early, and they may remain in heat till they come into flower, which will perhaps be a month earlier next year. By attending to shifting the camellias-plants from the warm house to the cold, a regular succession of flowering will be kept up from October to the following March. Those have even had them all the summer, but the flowers are best in the winter. Those produced in summer are far from being so fine, and do not stand half the time of those that come into flower in November, December, January, February, March, and April. Camellias delight to be kept damp all the summer months, and a little shaded from the sun. In winter, you are to keep them in water; they must have the same kind of water as for the rose. They never thrive but what are moist, and are also given a gentle sprinkling over the leaves once every week during the summer season, except when they are in flower. Camellias will stand a great deal of cold without being much injured, but they will not form many flowers without having a plenty of the most wholesome light. I find they do best in the tubs. I never shift them but once in two years, or often once in three years. There are several very large camellias here that have not been shifted these five years, and they are still in high health, having always produced above a hundred fine large flowers every year. Six years ago, I shifted a single camellia from a fourteen-inch pot to a sixty-seven inches wide by seventeen deep, and grafted it with two different sorts of double red, one double striped, and one double white: it is still in the same tub, and all the four sorts in high health. I have had all the four sorts in flower at once on it, producing a fine contrast.
colorful. The plant is large and handsome, being eight feet six inches high, and six feet nine inches wide. There is another plant here, twelve feet high, having upon it all the sorts I possess. They were only grafted last summer, and a number of the sorts are showing flowers; grafts of all of them have taken and are growing well. The plant is growing in a box sixteen inches over by sixteen inches deep." (Calcut. Mem. iii. 316.)

**Subsect. 4. Various Genera which may be considered as select Green-house Plants, showy, fragrant, and of easy culture.**

6619. Of other select green-house plants, the first we shall mention is the citrus tribe, already treated of as fruit-trees (4879.)—the beauty and fragrance of which need no encomium. They merit a house by themselves, though they will thrive perfectly in the same climate as the camellia. The myrtle comes next in order: nerium is a well known genus, whose flowers are of great beauty and long duration; fuchsia is universally admired; jasmine, gardenia, and daphne, have flowers of great fragrance; heliotropium is remarkable as smelling like new hay; various species and varieties of rosa indica and semperflorens are both beautiful and odoriferous, and flower throughout the winter. Among the new genera from the Cape and Botany Bay, acacia, minona, eucalyptus, melaleuca, metrosiders, and the protacea, are admired for being prolific in showy flowers, which, for the most part, appear early in spring; and being chiefly evergreens and large-growing hardy plants. Diasma, gniadia, and struthiola, are admired for their minute foliage and elegant flowers; those of xeranthemum are prized for their durability. Bignonia, coca, dolichos, jasminum, loniceria, and passiflora, are admired climbers; of passiflora some beautiful hybrids have been originated by Milne of the Fulham nursery. (Hort. Trans. iv. 258. and v. 70.) Mesembryanthemum, cactus, and yucca, are curious and beautiful succulents; amaryllis, cyclamen, iris, ixia, and gladiola, lachenalia, babiana, ferraria, and oxalis, are beautiful bulbous-rooted plants; and calla, celsia, cineraria, lobelia, tropaeolum, and jacobaea, select herbaceous sorts.

6620. The principal species of these genera will be found arranged in the following sections, with their colors, and other particulars, added to each. They are of easy culture and, with the genera of the preceding subsections, may be considered as affording the best choice for a small, showy, odoriferous, evergreen, and ever-flowering collection.}

6622. Propagation. The method universally applicable is that by cuttings; but a few sorts, which are very difficult to strike, are sometimes layered, grafted, or inarched, and a number are raised from seeds.

6623. Many green-house plants bring their seeds to perfection in this country; at whatever time these ripen, unless before midsummer, it is best to keep them till the following February. Sown at that season they soon vegetate, and make strong plants before winter. The pots should be well drained, filled with mould suitable to the species to be sown, and the surface covered with mould of the finest quality, as a bed for the seeds. Several kinds may be sown in a pot, where the quantity of seed is not great, or its quality doubtful; cover with the same fine mould, according to the size of the seeds, and then give a
gentle watering with the finest-rose watering-pot. They may now be set in the most dry airy part of the propagation-house, where they can be regularly attended, as to watering and weeding.

8. They require at least one, a day, in a greater or less degree; for if they are not kept properly moist, the seeds will not by any means vegetate freely, if at all; however, the other extreme is to be stolidly avoided. The seeds should be regularly pulled out before they attain any size; else, besides their tops smothering the young seedlings which may have started, the roots, if not removed from them, but also the seed, may be found, as it were, on the point of bursting their embryo. As the spring advances, it will be necessary to lay a few sheets of strong paper over the pots, for two or three hours in the middle of the day, if the weather happens to be clear, in order that the thinner seeds and those which are not requisite to prevent the surface getting over dry and powder-like; or, if the mould happens to be pretty moist, it is liable to form a mossy crust, which might be particularly injurious, by preventing the young seedling uising itself into the light, from penetrating through it with that ease which is requisite. In this case, the paper must be removed for a shorter period during the middle of the day, or, if the weather be cloudy, the sun may be removed to some shady border, where the pots can be plunged nearly up to the rim in coal-ashes or sand; which will greatly assist to keep them in a proper moist state: here, all the care they will require is to water, and every morning and evening, or, if possible, more often, allowing, if necessary, the sun shines strongly upon them, lest the tender leaves of the young plants should get scorched; it will be also necessary to have a careful eye daily for slugs, worms, &c. Should there be any fine light-covered seeds, such as heaths, &c. they must be set in such a manner, that they may be covered with a constant moist-bed frame, in a moderately exposed situation, so that in case of sudden or heavy showers, which might otherwise wash the seeds out of the pots, they may be occasionally covered to preserve them from such violence; yet they may be exposed to gentle rains at times, but never long together, lest they become over wet, which would soon perish them in this tender state. They will likewise require to be shaded with a mat in clear weather, or even a double mat, in the very hottest season.

6025. Potting off. Early in July, many of them will be growing pretty fast, and will require to be potted off into separate pots; as it is much preferable to do this while they are young and small, before their roots become matted together, than it is afterwards; besides, that they have a considerable portion of the root system in the mould of the pots themselves, before they are potted off, whilst forming this work, care should be taken that the pot to the size of the plant, and nature of the species to be potted; as overpotting these small seedlings might be of the worst consequence. The largest-sized plants, as Dahlias, are very strong, are what is called No. One, of the seedling-scale; such like very small articles, a still less size, known by the name of thimble pots, are to be preferred. Being provided with a quantity of these, and the different sorts of mould properly prepared, that may be requisite for the kinds to be done, proceed to pot the plants; in doing which, let the nice care be taken that the young seedlings, which, unless they are carefully handled, will be easily injured, are not have them potted in the proper mould, which must be gently pressed to the roots, that they may the sooner incorporate themselves with it. In this manner, pot as many as may be thought sufficient for the present purpose, at the same time allowing a few for mischances. They must then be well watered, in the morning or before the cool fame, on sunset, so that they may be well roofed, but free from any substance that will prevent the worms getting so freely into them, as they otherwise would. The lights must be kept constantly on, and closed, for a few days, more or less as circumstances may require; and it is very necessary that, from the strong heat of the sun at this time of the year, they be carefully watched, for a little time, the lights may be taken off at night, if fine, having them on, and shading in the day, until by degrees the plants are so hardened as to be able to withstand the full power of the sun; thus, in the space of a fortnight or so, they will be fit to be set along with the other plants. This business should not be even started, if the nights are not cold enough, as the seedlings will not have time to establish themselves; therefore, any that may remain in the pots, not strong enough to be parted by that period, should be removed into the propagation-house early in September, and there placed in their proper situation in that department until the spring following. Indeed, there are some seeds which absolutely require to be kept for that term before they will vegetate; whereby it becomes necessary to examine with care whatever pots have not by that time shown any signs of vegetation, and those which are found alive must be saved, and treated in the same manner as fresh-sown seeds.

6257. By cuttings. This mode of propagation may be commenced about the middle or end of January. As young shoots in a growing state generally strike most freely, where these are wanting on particular specimens, the plants may be forced for a few weeks in the stove, or in any of the pits in the reserve flower-garden, to produce them. All the soft-wooded, tender, pithy kinds, such as Indigofera, cramulaaria, polygala, huautan, chionias, &c., as well as some of the more curious genera, may require this treatment. By the end of February, the heat will have produced shoots of from two to four inches in length, and from that to any time in March, proceed to cut and dress them neatly with a sharp penknife, taking off all the leaves as close to the stem as possible without wounding it, except a few at the top, to be left for the free respiration of the cutting; this observation should be particularly attended to in making cuttings of evergreens in general, whether hardy or tender; let them be cut off at bottom with a clean horizontal cut, at a joint or bud, and immediately inserted in their proper pots. To have these properly prepared is a very necessary part of the business; being well drained, they should be rather more than half filled with the mould or compost best suited to the nature of the plant, and afterwards filled with good loam or sand, whichever may be

3 N
thought more advisable to insert the cutting in: if sand is used, it should be previously well watered, otherwise it cannot be sufficiently tightened to the base of the cutting; a most essential point to be observed, however, is that there should be time to be well drained off from the pot before the cuttings are put in; as they, being so tender, are extremely liable to damp at this season; than which nothing is more injurious. The loam will, in general, be found sufficiently moist of itself; and should it be of a fine, sandy nature, so much the better; but if not, a third or fourth part of fine sand should be added, and well mixed previous to its being used.

6628. Being properly planted, let them be covered immediately with the proper glass, well fitted, and pressed moderately on the mould, so as perfectly to exclude the air. They should then be plunged in the frame at the end of the propagation-house; or any other convenient situation.

The inside of the glasses should be regularly wiped with a dry cloth every morning; and any of them that happen to damp, carefully taken away before they contaminate the rest. If the sun happens to be unclouded, they must be shaded for a few days moderately with strong paper, or some such article; but by no means more than to cast off too great an amount of light to the afternoon sun, which are extremely susceptible of injury by over-shading. In the space of ten days or a fortnight, some of the free-rooting kinds will be making efforts of growth; as soon as this is noticed, it will be necessary to give them a little air, by taking the glasses off every morning, when the sun is quite receded from them, and putting them on again early the following morning; until they are by that means hardened, so as to be able to bear the full power of the sun without the glass, when it is to be entirely discontinued. If any of them should drop their heads when this operation is first performed, it is proper to refrain from moving the glasses up, and the softest zone of the sun at that hour will be necessary to dry up any damp that may have arisen as to be entirely done away while there remains any of them under glasses. In this manner is the business to be followed at different intervals, according as the cuttings are ready during the months of March and April.

6629. May and June is the most proper time for propagating most or all of the woody shrub-like plants; such as myrtles, oranges, metisadores, banksias, &c. and more particularly heaths, as the young wood will by that time be in general pretty far advanced. If this business is begun in June, which is early enough, they must, on account of the increased heat, be plunged in some cool shady situation; and not be exposed to the sun, except briefly shaded when requisite: an open and hot-bed in most instances will do very well; it will answer very well; or otherwise, the north side of any low wall or hedge, where they will be a little sheltered from the noontide sun, and have the benefit of it morning and evening; in either place, the pots must be plunged up to the rim in old tan or sawdust, and in the latter, they will also require to be covered with large cap-glasses over the small ones, as well mixed cuttings as heaths, except a few of the herbaceous sorts, such as arctotis, calendula, &c. and strong, substantial, broad-leaved kinds, as camellia, laurus, &c. which will succeed better without the small glasses at this season, as they are covered with a good growth of sinewy strong shoot, and strong shoot, as well as deciduous, as well as evergreen sorts, as pomegranates, oles, myrtles, &c.; which, in general only form their callusness previous to the ensuing spring, that do better without the small glasses, as their leaves drop off much sooner than too closely covered, than they do when differently managed; and therefore, if they should, that the strength of the leaves is not too greatly lessened the probability of success: this is to be merely understood as relating to late cuttings; for the same articles, if put in early in spring, very young, in a moderate heat, closely covered, properly shaded and dried, will strike astonishingly quick. The care of all of these is the same, and managed in the same manner. The whole being thus arranged, they must be carefully shaded whenever the sun acts violently on them, especially when first put in; but they ought not to be shaded longer than four or five o'clock in the afternoon, according to circumstances, as the mild influence of the sun at that hour will be necessary to dry up any damp that may have arisen within the caps. It will be also requisite to dry the small bell-glasses every morning, as directed for the spring cuttings, and to water occasionally any of the pots which may require it; for though it is proper to keep the top of the cutting dry, yet the mould in the pot must be kept as near a medium as possible between the extremes, otherwise it will notfree propagation.

6630. Potting off. Some of the first put in spring cuttings will, in May or June, require to be potted and potted separately in small pots; in performing which, be careful to avoid breaking the roots, using them much in the same manner as already directed for the latter part of the season, and for a few days, and shaded until they have established themselves in the fresh mould: as soon as they have taken to grow freely, let them be removed to a frame; but observe not to expose them to the open air entirely at first, as they might do them a material injury, on account of which, more curious kinds should be kept for a day or two more than the middle of June, the tenderer green-house cuttings that have been left in the propagation-house since spring, should be plunged under the cap-glasses along with the others: where the whole must be carefully attended to every morning, to pick off damps, dry the glasses, and water when wanted; it is advisable, when fresh watered, to let the glasses stand off for about a quarter or half an hour, to dry the surface a little, except the sun happens to be very clear, and shining direct on them. It has been already remarked, that there are many kinds which do better without the small glasses; such as the strong-growing, spongy, and succulent kinds; also those with thick leathery leaves, as the camellia, which are not so easily scorched by the glasses collecting the rays of the sun. Any time during the months of June or July, cuttings of these sorts may be made with success; as by that time the young shoots will be sufficiently firm for that purpose, and will strike freely in good loam: but camellias, and such like sorts, should be cut off the shoots when the flowers are finished; and be very likely to strike, except when young, particularly subject to rottenness and damp. In July and August, there will be many of the earlier cuttings growing; they should have their glasses taken off, as before directed, and afterwards be set for a few days in a more exposed situation, to harden them by degrees, in which they may be exposed from the middle of July onward, but freely exposed to the air at night.

6631. Parting and potting should also be occasionally performed on such as are ready for that operation; when, if any of them happen to be more backward than others in the same pot, and not rooted, let them be put in again as cuttings, and treated as such; those which have risen from the middle of June, and are young, but not quite rooted, may be set in a dry airy part, where they can be carefully attended to, prevent their getting over dry or dirty, and also to take the glasses occasionally off those which may be growing. All the backward heaths, proas, or any other hard-wooded kinds, such as are most of the Botany Bay plants, &c. that take a long time to strike, should be set as cool and dry as possible, in the hottest part of a hot-house, where they must be watered and cleaned, like the others, throughout the win-

Part III.
ter. Towards the commencement of the new year, many of them will begin to grow, therefore the glasshouse must be taken off such as soon as necessary. With the advancing season, these will likewise advance, and soon come to be filled, and then separately (1643. Gard. Lith.)

6633. Almost all the woody green-house plants may be propagated by cuttings; but a few are occasionally layered, or grafted, as the camellia, citrus, daphnie, &c. which have been already treated of.

6634. General culture of woody green-house plants. We shall commence with the shifting season, which generally takes place about the end of May, and trace, from Cushing, an outline for their general culture and management throughout the year. Greenhouse plants, this author observes, for the most part require a considerable share of pot-room, as many of them are very free growers; but still great caution is necessary to avoid over-potting the tenderer weak-growing kinds. When shifted, let them be neatly tied up, if requisite, and well watered. Any dead or ill grown parts can now be, with propriety, cut away, so as to give the heads a regular neat appearance. In bright sunshine it may be also necessary to shade them for a few days from the influence of the sun and winds, until they are perfectly established in the fresh mould.

6635. Placing in the open air. By the middle of June, it will be time to think of preparing the out-door departments, in which it is intended the plants should stand during the summer months. The most eligible situations for this purpose are, the north aspect of vacant walls or hedges, where they will be a little shaded from the noontid sun, or between rows of close hedges, particularly planted for, and solely appropriated to this purpose. By no means set them close under the shade or branches of large trees; as the plants are thereby inevitably drawn into a weak state in a few weeks, and those who adopt such situations are not unfrequently under the disagreeable necessity of throwing away many of, perhaps, their most valuable plants, which remain without any protection. In a well-deeped, shelter from the winds is the great desideratum to prevent their being upset, for most green-house plants are fond of the warmth of the sun, except when recently potted, provided their roots are kept moderately moist. The practice of some gardeners is to plunge them amongst the shrubs and flowers of the pleasure-ground; this is far better well with the strong-growing kinds, such as myrtles, geraniums, coronillas, &c. old plants or supernumeraries that will not be wanted to house in the autumn; and even has a very pretty effect when judiciously done; but it will by no means do for the tender species. Therefore, upon the whole, the most unexceptionable situations are those as at the same time afford a moderate portion of shade, and are secured from the force of those strong gales which frequently blow by the summer and early autumn months, and yet allow that free circulation of air so necessary to the well-being of plants in general, and at all seasons. Having fixed on the place where they are to stand, it must be remembered that, as may be seen byaly, neatly cleared away. It should be so arranged that it may make it perfectly firm and level, over it a layer of good time, slacked and made into the consistency of thick white-wash, should be poured, and left to soak into the surface, as a preventive against worms getting into the pots. When this is dry, let about an inch of finely sifted coal-ashes be regularly laid on, and the plants be set on the ashes, the plants being brought out of the green-house, the plants and level on the surface, in whatever form or arrangement may best suit the situation or the taste of the cultivator.

6636. Housing in autumn. As the tender shoots of the summer’s growth are extremely liable to be injured by the frost, as soon as any symptoms of this appear, they should be removed to their winter quarters, where, if the green-house is built on a proper principle, they can still have the benefit of the free air, and at the same time be in a situation to be protected when necessity requires. They should, at all events, be removed in the earlier part of September. Therefore, about a fortnight before that time, they should be regularly examined, and any roots that may have extended themselves through the holes at the bottom of the pots, cleanly cut away: this tends to stop the too luxuriant growth, and being executed at a proper period, before their final removal, they have time to recover themselves from the partial checks of the cold winds, in which they are at first enduring too severely. If they are removed before their time, moving them into the house; the transition from the cool bottom on which they stood, to the dry boards of the green-house stage, being so materially different. Whatever may be the mode of arrangement adopted (6635.), the plants must not be set too close when first put in, as it would occasion most of their tender shoots to be injured, and as they, if the house happens to have been built on a close construction, be by any means taken in when their leaves are wet.

6637. When they are all housed, and dirt of every description taken away, let as much free air be given as possible, to render the atmosphere the more moderately cold, and prevent the appearance of any appearance of frost. Frosts, at this early season, are seldom so severe as to injure any green-house plants that were not immediately exposed to its perpendicular effect; therefore the front windows may be kept open continually, unless there is a prospect of its being particularly severe, or accompanied with cold winds, in which case it is necessary to have the doors open. If the temperature is not too far removed, moving them into the house; the transition from the cool bottom on which they stood, to the dry boards of the green-house stage, being so materially different. Whatever may be the mode of arrangement adopted (6635.), the plants must not be set too close when first put in, as it would occasion most of their tender shoots to be injured, and as they, if the house happens to have been built on a close construction, be by any means taken in when their leaves are wet.

6638. Water should also be plentifully administered when they are first taken into the house, as the dry boards on which they now stand, as well as the elevated situation and free circulating air, occasions them to require less than when they stood on the moist earth; however, by no means go to the extreme, giving it only when evidently necessary.

6639. As the close foggy weather advances, water must be given more sparingly, else it will conpire with the atmosphere to increase the dampness of the house, which will inevitably injure the plants, by rotting their leaves, and bed dead flowers. It should be picked off as soon as they are observable, otherwise they will make a very disagreeable appearance.

6640. The months of November and December seem to be more noxious to the health of plants than any other season. The remainders of the sun’s heat is almost entirely spent on the greenhouse, and the flowers still on them, when the weather (which at this time generally becomes close and chilly,) renders it necessary to keep the house shut and warm; this occasions most pernicious damp to exhalate from every part of the house, and even from the earth in the pots, which fixes on the leaves, and other parts of the plants. If they are in too large a proportion of the weaker parts, the ensuing winter, and result of which is, the producing the succeeding summer. If this kind of weather continues for any considerable time, it will be advisable to give a little fire-heat, to help in drying up these banefull exhalations, and also as much air as can be safely admitted by the doors and front windows, more especially when fire is added, otherwise the heat of the flames will be in danger of expelling the cold, and instead of exhaled air, rather occasion it to exhale more free, and be of worse consequences. At this season also, the plants should be regularly examined to clear them of all dirt, and

2 N 3
also to scrape off any moss, &c. that may have grown on the surface of the mould, and to renew it with a little fresh loam; this contributes much to their good appearance, if neatly executed.

6641. Fire-heat. Very little fire-heat seems to be requisite for the preservation of green-house plants in winter, but, the less it is the better. Except in the case of damp, as before mentioned, it need not be used till the frost be so severe as to lower the thermometer several degrees below 45°, and then merely sufficient to raise it again to that point. If this can be done without the assistance of fire, so much the better; for which purpose, bass mats may be used along the lower parts of the houses. If heat can be obtained at a cheaper rate than the fire-heat, water should be used, as less of that element will suffice; but they should be always taken off in the day to admit the light, unless the weather happens to be particularly severe. It may be also proper to remark, that the more dry the air is, the more the warmth of the fire-heat is kept at the bottom of the houses: therefore, water must be used very sparingly, and only to such as are in actual want of it. Sometimes, in the depth of winter, there is a succession of very clear weather for several days together, wherein warm sunny days succeed the coldest frost, and nights in which fires have been absolutely necessary; in this case, it will be necessary to diminish the air, and to cover the glass as much as possible, and the more so in the daytime, and to remove all the air that can be spared, (in the daytime, vents, happen to prevail,) observing to shut the windows up close early in the afternoon, so as to include part of the natural heat of the atmosphere within the house. Such weather renders an increase of heat unnecessary, especially over the entrance of the fires, where the fires have the greatest force. It should be observed, that in the harvest season, the water ought to be made to flow down the tram-plates, if the air contains much dust or pollen, particles it may have imbibed, and render it nearly equal to the temperature of the air of the house. But unless water becomes actually necessary by the action of the fire, or the extreme drought of the season, (a circumstance not much to be dreaded in our climate at this time of the year,) the less water used the better; for though the plants in general like to be kept pretty moist in the summer, there is hardly any thing more pernicious to them now than an extreme of moisture.

6642. Winter and spring treatment, insects, &c. During the months of January and February, and, indeed, all through the winter and early spring, on account of the necessary closeness of these departments, it may be expected to see a few dead or yellow leaves on the plants; these, together with the dead flowers, and whatever damps may occasionally appear, should be picked off as soon as discovered.

6643. The mildew and green fly will also be paying frequent visits at this season; particularly on the young shoots of heaths, and such like tender-leaved plants. The best remedy for the first of these is, to procure about equal proportions of sulphur and roach-lime, slacked and finely sifted, the quantity according to the number of plants infected, to be used in the following manner: As soon as the least symptom of this disease is perceived, (for the sooner it is stopped the better,) which makes its appearance likely, by the appearance of the mildew, or green fly, the leaves be gathered down in the bottom of the sheds, or of which plants they are in the pots, by their casts on the surface. Indeed, this is a thing that should be attended to at every season of the year, as they are to be observed more or less at all times, and considerably disorganise the economy of the pot, when suffered to persevere.

6645. Towards the end of winter, the plants should be regularly examined, and cleaned from any filth they may have acquired during that dreary season; such as moss on the surface of the pots, and leaves that have dropped thereon; also any plants that may have grown into a loose habit should be tied up. The platforms or stages should be clean brushed, whilst the plants are removed, and any worms that may have harboured in the pots dislodged, by turning them upside down, and lifting them carefully off without breaking the soil, so as to destroy the bottom of which they are in the pots, by their casts on the surface. Indeed, this is a thing that should be attended to at every season of the year, as they are to be observed more or less at all times, and considerably disorganise the economy of the pot, when suffered to persevere.

6647. Treatment of green-house plants in a conservatory. This should resemble the treatment of plants in pots, as far as the difference of circumstances will permit. The plants in the conservatory cannot be set out in the open garden; but the roof can be removed to produce the same effect, and should be done about the same time. Instead of shifting, the soil can be refreshed by manure and top-dressings, or it may be entirely renewed; and pruning, training, and attention to cleanliness and neatness are alike applicable to both modes of culture. When the green-house plants are housed, the lights or roof of the conservatory should be replaced. The plants, in the meantime, will require as much air as it is possible to admit on all fine days, and in case rain prevents the letting down of the roof-lights, the front ones, if any, should be as open as possible. This is to prevent the plants being drawn into long naked stems, and weak branches, which, from their free habit of growth, they inevitably otherwise would be. As the cold of winter increases, which it naturally will do in the months of October, November, and December, a proportionate decrease must be observed in giving either air or water;
CLIMBING GREEN-HOUSE PLANTS.

and, if necessary, add a little fire-best, and mats along those parts of the glass nearest the plants, in such manner as to prevent the frost or piercing winds from injuring them. The conservatory, in these particulars, requires to be managed in the same manner as directed for the green-house. As few objects are more desirable than to preserve the gay appearance of the plants, it will be requisite to pay constant attention to the removal of decayed leaves and weeds of every description; also to tie up or cut short any loose straggling branches that happen to show themselves, to remove those pots which may have been plunged or set on the pit when out of flower, and, if convenient, to have their places supplied with others in a fresher state.

6648. During November, December, January, and February, the moisture of the atmosphere in such departments, where there is a great body of damp mould, will occasion several species of the bryum, and other mosses, as also the lichens, and other vegetation, which has had time to settle, and the surface to become of a close firm texture, which would give the house a very unclean appearance. It must be remedied by frequently stirring with a small fork the whole of the pit, to the depth of two or three inches, and raking it over smoothly with a neat close-toothed rake; which, as well as the fork, should be particularly adapted to this purpose, by being furnished with short handles; so as to enable the operator to use them with freedom under the plants, by which means many branches and flowers will escape being broken, which cannot be well avoided when awkward tools are allowed to be used for this purpose. As soon as raked, let some fine-sifted fresh loam be thinly scattered over the surface, and it will tend to give it a more agreeable appearance; besides, being dry, it will serve to imbibe a good quantity of the superabundant moisture.

6649. As the spring advances, they will require considerable attention to keep them in proper order, on account of their great increase of growth, more particularly the climbing plants, trained against the walls or trellis-work; these should be daily attended to, and trained in their proper places; directing their course to those parts of the house which, from their nakedness, appear to want them most; also these species of plants being remarkably free growers, it will frequently be found necessary to thin them, by cutting away any unsightly parts, and those branches most destitute of flowers; by which means there will be sufficient room for the young vigorous growth, and these should be trained in regularly as they advance, otherwise they will attach themselves to the first object they meet, and render it difficult to dress them neatly afterwards.

6650. Slugs, snails, and other vermin, are very fond of harkering among the leaves of these plants, when permitted to grow crowded; also under any low bushy plants in the pit, whence they make their nightly excursions, to the great injury of the foliage in general, if not seasonably detected. The drought and warmth increasing with the year, will render it convenient to admit more air, and an increase of water; two very essential points, that should never be neglected.

6651. In summer, the lights having been removed, as before directed, the plants should have any necessary pruning, and be all regularly fresh tied up, to secure them against the free action of the wind; they will, if the weather happens to be dry, which is most frequently the case at this season, require an abundant supply of water, particularly the strong free-growing sorts, on account of being thus exposed to the open air. The cause for thus taking off the top-lights every summer is, that the plants may have the benefit of the warm invigorating showers of that season, and the action of the perpendicular air, which will be a great means of their acquiring that strong, healthy, robust growth, so much wished for: indeed, where it is not practised, the plants seldom fail of being drawn into the opposite unsightly extreme. In two or three years from the first planting, many of them will be grown to as large a size as the house will admit of.

The knife must be frequently used in pruning such, to keep them within bounds, and prevent their injuring each other, which they inevitably would, if permitted to grow too close together. However, in performing this, one must be very careful lest they disfigure the general appearance of the plant, cutting away only the rubbish and excess, which should be taken off, without grinding the surface, and the stumps behind. The younger parts which are suffered to remain should then be tied neatly up, so as to form a handsome middling-sized bush. It will also be necessary to observe whether any have outgrown their neighbors in the front rows; these may conveniently be moved into more backward situations, and their places supplied with other new varieties, if to be had. This work may be done with safety any time in spring or autumn, when the weather happens to be a little dull; it will be advisable, however, to cut off a few of the most luxuriant shoots, and to run a spade or large trowel down, around the roots, so as to form a ball, some days previous to its final transplanting, which soon operated splendid check on the free growth of the plant. It should be taken up with a good ball of roots and earth, and well watered as soon as replanted: it may also be found requisite to shade such as are thus removed lightly for a few days, if the weather happens to be very clear.

**6655. Propagation.** With succulents this is remarkably easy, as cuttings and suckers, where they can be procured, seldom fail to put out roots; however, some sorts of aloe, crassula, &c. do not readily produce shoots of any sort by which they may be multiplied. When the leaves are taken off cuttings or suckers, the latter should be laid in a dry airy place, till the wounds heal; they may then be planted in the proper soil, one in each of the smallest-sized pots, and being kept a few weeks in a dry heat, and shaded from too much sunshine, they will soon start to grow. In raising succulents, the seeds, when in a dry condition, are sown among the most suitable soil, as the common peat or loamy soil; these seeds, when sown as directed are usually speedily produced by the seeds of woody plants; observe to be more sparing of water after the plants come up.

**6656. Culture.** A sandy loam is the soil universally allowed as the most proper for these plants; not of the finely sifted, in order to let the water pass the more rapidly through it; and for the more succulent and dwarf sorts as stapelia, cactus, &c. about an eighth part of old lime-rubbish may be added. Succulents do not associate well with any other description of plants, neither as to appearance or modes of culture; therefore, wherever they are extensively cultivated, there should be a house or houses on purpose to be set up for them. One house would be required for the more hardy sorts included in this section, another for the dry-store succulents, given in a succeeding table. They require very little watering, and never over the top during the winter months; in summer, if the pots be well drained, they will bear more water, especially when in flower. The pots in which they are placed should be smaller in proportion than for other plants, as they grow slowly, evaporate little, and apparently derive great part of their sustenance from the air. They need not be shifted oftener than once in two or three years; but the surface earth should be taken off, and fresh compost added every year. They do not require to be set out in the open garden during summer; but a moist air as possible should be admitted to them, and the roof of the house should be open at that season, night and day, excepting during heavy rains. "The greatest injury." Page observes, "which these plants have to be guarded against, is damps in winter; therefore they should be frequently looked over, and all decayed parts removed, particularly from those which are stemless, and when the leaves touch the earth." He adds, 4 or 5 of these plants, either their own of the greenhouse or hot-house, are cultivated in general, but merely to fill up the by-shelves and odd corners of the exotic houses; but if a proper attention was paid to them, and their cultivation better known from a study of their characters, we have no doubt but they might be rendered as ornamental and interesting as those now considered the most select. Most of the forms and growths of these plants are truly curious; and many of their flowers of the greatest beauty and brilliancy. Since the days of Dillenius and the late James Lee, these plants have had few admirers; but the present Emperor of Germany, the Prince of Salm, the Vicc-king of Lombardy, and our countrymen Haworth and Anderson, the latter the able curator of Chelsea Botanic Garden, are endeavoring to bring them again into notice which they so deservedly merit." (Prodrumus, 220.)

**6657. Mesembryanthemums.** are planted out by Mowbray, in a position the front wall of a hot-house. They are chiefly rich in the middle and fresh loam; 4 the sorts are M. includens, and M. perfoliatum, detolfa, barbatum, and other species of different habits; the strong-growing kinds are put towards the back, and the dwarf ones in the front. They grow vigorously, and flower in a superior manner to many other sorts; most of the flowers are the brilliancy of the season, and the true beauties of the summer, and many of them continue flowering all winter. All the culture they require is thinning and protection by masts over the glass in severe weather. In summer the sashes are taken off, and the soil may be covered with stones like rock-work." (Hort. Trans. v. 274.)

6693. Propagation and culture. After the ample directions on the subject of propagating and cultivating bulbs, already given (6691.), very little can be added here. A mode of propagating such as rarely produce offsets may be mentioned: it applies only to tunicate bulbs, which, if cut over transversely, a little above the middle, will form young bulbs in abundance near the margin of the outer coat. This has been successfully practised with hemeranthus pubescens, and several of the more rare ornithogalum. The grand art in cultivating bulbs is, to attend to the proper time for putting them into a state of rest; and when they are in a growing state, to place them so near the light, and afford such a supply of air and water as will enable them to bring their leaves to perfection. The management of exotic bulbs is, in general, very imperfect among gardeners, who cannot be too much impressed with the importance of attending to these two points.—The perfecting the leaves, and the putting the bulbs into, and keeping them during a proper time, in a state of rest. Bulbous-rooted plants associate almost as ill with all others as succulents do; and, therefore, wherever a good collection is kept, there should be a house entirely devoted to their culture. The roof should be low and not very steep, and the pots should be kept on a level stage or platform, raised table high, or about two feet and a half, that the flowers may be near the eye. A house, glass on all sides, with a central platform, six or eight feet wide, and two side ones, or side borders, about three feet wide, would form an excellent house for plants of this description, as all of them would be near the glass, and near the eye of the spectator. Whenever the bulbs, cultivated in such a house, became in a dormant state, they could be removed to a pit or frame of proper temperature in the reserve-garden, and kept there dry, till the growing season. Exotic bulbs require nearly the same degree of heat, when lying dormant, as they do when growing.

6691. Propagation and culture. A small house, constructed like a bulb-house, should be devoted to these plants; some of which are of considerable beauty: but they do not assert well with woolly and evergreen species. All the difference between the culture of hardy, and exotic herbaceous plants, consists in the latter being kept in a different climate and in pots.

SECT. VII. Of Selections of Green-house Plants for particular Purposes.

6662. The particular purposes to which green-house plants are applicable are few compared with those for which plants which grow in the open air may be selected. The most hardy species will be found arranged as frame plants; the most showy and odorous under the first four sections. There are scarcely any green-house aquatics; but a few marsh plants; and no parasites, or air plants, suitable for the green-house, have been introduced hitherto. Collections, however, might be made of such as are grown in their native countries for useful or economical purposes, and whose produce is imported to this country, as of Laurus camphora, the camphor-tree; Pistacia lentiscus, the tree which affords mastic; of such as are highly odorous, as Verbena, Heliotropium, &c. In a botanical collection, Dionea and Sarracenia are plants of great rarity, and difficult to preserve or propagate. They are generally procured from their native countries, and grown in peat-earth, kept moist, and the atmosphere also rendered humid by covering them with a hand-glass. Cresswell has produced very strong plants of S. purpurea, by treating it as a stave plant. Under his management, "it is planted in a mixture of the fibrous roots, obtained from peat-earth, with an equal quantity of rotten willow wood, broken into small pieces, by which the soil is kept perfectly drained. The pots in which the plants grow are kept in a shaded part of the stove, and watered occasionally, but they do not require to be placed in pans of water, except they become so dry as not to absorb the water given in the usual way." (Hort. Trans. iii. 360.) Some fine specimens of these genera, and also of Nepenthes distillatoria, are contained in the collection of Mesars. Lodidges, at Hackney.

CHAP. XIII.

Dry-stove Plants.

6663. What are called dry-stove plants are such as from experience have been found to require an intermediate degree of heat between the green-house and bark-stove plants and a more dry atmosphere than the latter. Their propagation and culture is the same as for green-house plants; with this difference, that they are not in general removed to the open air during summer; but where the construction of the house admits, the ashes may be removed in dry weather during the three warmest months, but always replaced on the commencement of heavy or cold rains and boisterous winds. We shall arrange them as woody, climbers, succulent, bulbous, and herbaceous plants. To cultivate them to any degree of perfection, it is essentially necessary that a house be appropriated to each section; and each house so arranged as that the plants may be near the glass, and that heat and air may be supplied at the pleasure of the cultivator, or a long narrow house may be divided so as to keep each class separate.
6669. Bark-stone plants are such as require the highest degree of heat, which has generally been given by the aid of a bed of bark or other fermenting substance, in which the pots containing the plants are plunged. Sometimes, as before observed (6184.), steam or fluxes are applied under a vault covered with earth or sand as a substitute for bark; and more recently the pots have not been plunged in any material nor bottom heat applied, but a greater atmospheric heat communicated, and the atmosphere about the pots kept moist by watering, &c.

We shall arrange the most ornamental species which flower freely under woody, climbing, bulbous, perennial, annual, aquatic, reedy plants; and add some remarks on palms, air plants, and ferns, which, though they seldom flower in this country, or for the greater part have flowers of little show, yet are grand or interesting specimens of vegetable beings.

6671. Propagation. All the known modes are occasionally adopted, but those by seeds and cuttings are the most general. Few stoke plants ripen their seeds in this country, and such as are obtained are therefore generally procured from abroad.

6672. Tropical seeds in general, Cushing observes, are very liable to lose their powers of vegetation by reason of the transition from warm to cold climates, combined with the length of time which commonly intervenes between their gathering and arrival with us, especially if they have been exposed to damps; on that account they should be sown as soon as they arrive, at least a part of each parcel. Much depends on the state of the seeds when received. East and West India seeds generally arrive with the regular fleets, as indeed do those from the Cape of Good Hope, and all the South Sea islands, for the most part by the Eastern and China ships; so that one may in general be prepared against their arrival. As early spring is undoubtedly the best time for sowing, a few weeks' delay in some instances be advisable. If received late in October or November, wait until January, or perhaps February, unless it evidently appears that they will not keep out of the earth so long as in a vegetative state; such as can be sown before August have a good chance to acquire sufficient strength of growth to carry them through the winter months, so adverse to the general efforts of young vegetable life.

6673. The pots being well drained should be filled with the compost suitable to the species of plant of which the seed intended to be sown has been produced (see the Table); let it be pressed down about to a third or half an inch below the edge of the rim, according to the size of the seeds; if they are small or light sorts, it will be necessary to press it very tight, and to add a little of the very fine-sifted mould on which to deposit the seed, previously smoothing it with a bit of thin flat wood, bent so as to lie on it level. Being thus prepared, let the seed be sown regularly on the surface, and cover it from about an eighth to a quarter of an inch, according to the size of the seed as before, with the same sort of fine mould. But if the seed is of the largest sorts, as, for instance, the nut or stone kind, no more is necessary than to press them into the earth with the finger, and to cover somewhat thicker than is recommended for the others. In either case, the covering should be pressed moderately on the seed with the hand; which is indeed a most necessary caution in sowing seeds of any description whatever. In order to ensure the vegetation...
of hard or very tough shelled seeds, some have them soaked in water for a few days, say a week, or even ten days, for such as happen to be very dry, previous to sowing: a shallow pan, placed on the coolest part of the floor, will keep them moist, and in a few days the germs will appear. These should be examined daily, and soon the moment any sign of swelling or growth appears; this process, however, is fraught with danger to many of the lighter and smaller sorts.

6675. By cuttings. Besides the usual supply of the different sorts of earth, &c., there is another article necessary to be provided before we begin the business of making cuttings: which is, a few dozen of small bell-glasses, (the white glass is best,) of as many different sizes as are the pots in which the cuttings are intended to be planted; they should be fitted to the pot, so as to rest on the inner side of it, about an inch below the rim; by observing which circumstance, when the pot is filled with earth, the glass will have room sufficient to sink a little into it, so as to perfectly exclude the external air; of very essential importance to the cutting while in a dormant state, that is, from the time they are put in until they begin to grow.

6676. The cuttings may be made almost every season of the year; yet the months of April, May, and June are certainly the most proper; as the plants are at that season plentifully supplied with young wood, which, in most species, produces cuttings into which a much larger proportion of the vitality of the plant is concentrated than in the old wood. If they are used in the same manner. When the day is fixed upon for this business, let a quantity of pots of the proper size be selected, and prepared by covering their bottoms to the depth of one or two inches with potting soil, then filled with a mixture of loam and leaf-loose, that is intended to be propagated, to grow in for a few weeks, when first struck, and the remaining part with the best loam that can be procured, to insert the cutting in when ready. On the purity and cleanness of the loam depends in a great measure the success of many of the tenderer kinds of cuttings, particularly those which are oblique, and those which, when planted, may be confined only to pure water, to prevent any action of dampness or rottenness, by the particles of putrefying matter generally contained in mixed earths, and the properties of which are put in motion, by the application of heat. As an exception to this rule, may be added sand, which is of very great utility to mix with the loam, should it happen to be rather stiff for the nature of the cutting; but then, the sand proper for this use is of so pure a nature in itself, that it is evident it cannot have the effect noticed above in regard to mixed soils.

6677. In the choice of cuttings, preference should be given to the firmest wood of the same year's growth; and to the shoots whose leaves are small, and of the greatest thickness, which usually may be selected from the lateral shoots; as the upright leading ones are mostly too luxuriant to make good cuttings. The cuttings of many plants, if taken from the lateral shoots, never become proper erect stems; but are inclined at all times to form an irregular, bushy, weak head: this is not of small importance to such plants as those which produce flowers for the greenhouse, and others which are esteemed by florists as elegant, and are consequently purchased on the strength of their appearance. Of these, the tops of the shoots are always to be preferred; to be prepared for insertion, most of the leaves must be trimmed off close to the stem, leaving only a few at the top, to allow a free respiremation of the air necessary to the life of the plant. This is a most essential article in the art of making cuttings, particularly those of evergreens; for if they are deprived entirely of their leaves, or that they otherwise flag, or occasionally fall off soon after they are put in, there will be little or no chance of their growing. The reason is obvious, because the inherent sap of the cutting, being deprived of those organs of respiration that keep it in motion, and the cutting having no roots by the efforts of which to produce new leaves, the sap, consequently, becomes stagnated in the pores of the wood; which, like the stagnation of the blood in animals, will in all likelihood prove mortal, by occasioning an immediate mortification.

6678. In shortening each cutting to the most convenient length, care must be taken to do it with a clean cut, in a straight line; the protestation of the cutting on no my part is to be needed, if of late. In planting, a small dibble or other convenient instrument should be used to press the loam sufficiently tight to the base of the cutting, so that the principal part to be made fast; as soon as the whole are inserted and the surface of the mould made level and a little firm, give them a gentle watering, they should be kept to soak, covered with a bell-glass, which should be pressed pretty tight, so as perfectly to exclude the outward air. The atmospheric air being prevented by the glass from exhaling any of the juices of the plant, all its powers are forced downward to produce roots, and these will soon prove their existence by producing young leaves and flowers, and there are several cuttings of the same sort, they may be all put in one pot, unless they happen to be very large or curious sorts; but in general each species should be kept in a separate one, on account of the difference in time that some of them require to strike roots; and also, that any scarce or valuable species may be planted only one chance in the pot, as the heady air is not sufficient for too many, or, if neither do they require to go through the precocious operation of separate potting, so soon after being struck. Should it be requisite to have a considerable quantity of cuttings made at the same time, it would be proper to have a one-light frame, with close glasses, perhaps from two to three, and a hot-bed, the pots being put in for clean tan, about a foot deep, in which to plunge the pots, but if there are only a few done, they may be plunged in any frame among other things, provided there is a moderate heat.

6679. Watering and shading. They will now require the most particular attention as to watering and shading. The water must be given twice or thrice very moderately until the earth becomes sufficiently moist, which, if once so, will retain the moisture for a length of time, by being covered with the glass; but the shading is the principal care whenever the sun's rays fall on the glasses, as nothing will create rot-
tenness sooner than letting the leaves flag, and lie upon each other, which will be the positive consequence of a neglect of shade. The most admirable device to do this, to have a few large sheets of strong paper to hang in the hot house, and cut them in such a manner as will prevent the sun's rays from entering the frame and clearing off any damps that may be accumulated therein; whereas, if mats are laid on the outside of the frame-light, it is evident they will tend to have the same injurious effect. Hence, if it be once a week or fortnight, they will be able to withstand a little of the rays of the morning and evening sun.

668. While in an inactivity state, they should be kept rather dry, but not to an extreme; else the bark will become shrivelled, and occasion a very smart falling off amongst them; on the other hand, should they be kept very damp, they would not soon dry sufficiently after damp occasioned by the air being so closely confined under the glasses; in this case it would be of infinite service to have the glasses wiped with a dry cloth about once a-week, which is quite sufficient for hot-houses, and they are not so liable to suffer from this cause as those of green-house plants.

669. As the heat of the bed does not become necessary to have the frames really ready, in which to plunge them when requisite, or else, let the old one be renovated with linings of fresh warm dung; but in such manner as to avoid creating any violent degree of heat or strong rank steam in the bed, as this will injure them in a time, but a trifling degree of heat, as compared with the probable consequences. By this management one may expect to have some of the free-growing kinds well rooted, and making rapid progress, in the course of a very few weeks; when such is the case, it will be necessary to give them a little air by taking off the bell-glasses at night, and to keep these open the next day, as this pretty well for a few days, as to make them be entirely ready, which will harden and prepare them by the time in which it may be thought convenient to part and pot them separately.

670. Taking the bell-glasses off at night, it is necessary to observe that from their closeness they sometimes occasion the cuttings, more frequently the harder sorts, to produce young leaves and even shoots, before they have sufficient roots; if at any time these should be mistaken for well rooted plants, and their glasses taken off accordingly, in a few hours they may be perceived by their leaves beginning to flag and wilt, and consequently, if not immediately replaced; otherwise, if neglected, these tender shoots will be utterly spoiled, and it will be a very great chance whether the cutting will ever produce more or not. Should the above circumstance happen, they will be observed to be more impatience of damp afterwards, as indeed will all those be which are growing; the glasses should therefore be more frequently dried, and the shoots protected under them, by a mat or other similar covering, until they succeed, I may say, perhaps, their existence, by rotting the first weak efforts towards active life.

671. The rooted cuttings being thus prepared, they may be occasionally taken out of the frame, and set in a rich hessian compost; but as some have a habit of sprouting from the base of the shoot, it is necessary to keep such still in the frame, shading and watering them when requisite, as already directed. Thus may they be treated until the autumn; when, if any yet remain in the cutting state, it will be advisable to have them taken to the propagation-stove, and plunged in the frame to make the damps, most particularly of those that may be obtained by them, and renewing the surface with a little fresh loam. Here they will require the same care as when in the frame, except that as the influence of the sun decreases, so must the shading in proportion; using it only for two or three hours in the middle of the day, if at all requisite; and indeed it is necessary here to observe, that in the winter, and early spring months, they may not be exerted on any account, nor watered except when absolute necessity requires it; neither should the cuttings that may be occasionally these seasons, receive any water when first put in, as directed for those made in summer, as the mould would otherwise become injurious, and as there is now no quick pressure to introduce water: at this season, the water might prove materially injurious, by promoting damp and rottenness. It is even necessary in some instances, should the cutting be of a succulent plant, or in any degree approaching that nature, to provide loam rather dry, than moist; in which they must be planted and left without water, for a few weeks, but afterwards, and the wounds are healed; however, in either case, those fresh put in must be partially shaded for a few days, should the weather happen to be clear and sunny. It will be also necessary to dry the inside of the bell-glasses more frequently in the winter months; as there is generally a stronger heat kept in the tan-pit, which gives rise to an increased evaporation, and damp at this season should be more particularly avoided than at any other. In the ensuing spring those put in early, as well as what have remained since the preceding summer, will in general make an effort to grow; as soon as they are observed in this state, let them be managed in the same manner as those already rooted hard.

672. In regard to parting and potting the rooted cuttings or seedlings separately, the greatest nicety should be observed; first, in turning them out of the pots without lacerating the roots; and secondly, in shaking and working the earth from amongst them, until they can be readily parted without breaking; the rule to observe here, is to part them, as much as possible, but not to split them; the roots should be the principal object. They must be immediately potted in their proper soil, in pots suited to the size of the cuttings, and neatly tied up, if necessary; let them be then well watered with a soft pot moderately fine, but no means should they be fisted, or thus left with it, as too many are apt to do, but let it be given gently, and time allowed for it to soak regularly into the mould. They will require a brisk heat and close shading for a few days, until they have established themselves in the fresh mould. (Exotic Gardener, 26.)

673. Laying and inarching are rarely practised on hot-house plants. However, there are some that do not produce roots freely by cuttings, which may be multiplied successfully by these methods.

674. In laying, choice should be made of the young tender shoots of the present year; the soft bark of which will sooner form a callousity, and produce roots, than that of any of the preceding year's growth. It is particularly necessary to observe whether the plant intended to be laid is of a brittle nature or not; for if it is, it will be necessary that the shoots be pegged gently down to the surface previous to laying, and thus left until their tops naturally acquire a perpendicular direction, which they will do in a few days; without this precaution, it would be extremely difficult to cut or tongue them without cracking, or breaking them off; but if treated in this manner, the best brittle may be laid without danger. It is a conclusion drawn from several experiments, that the layering is best to which is first, and the shoots; the reason of which is, at a certain depth the air is better excluded, and there is a more regular degree of moisture for the nourishment of the young fibres, when they make their appearance. No part of the shoot should on any pretence be covered with the earth, neither must they be fisted, or this layer thus laid, as the covering the shoots to rot; and therefore, if any particularly tender plant should happen to be thus treated, it would evidently endanger the whole stolp.

675. Inarching is much preferable to the common grafting, for evergreens in particular; it is principally inarching that is the best means of multiplying all the double varieties of camellia and plants of similar habits; because their strong leaves, if only for a few days deprived of their regular support, by being cut clear from the mother stock, if not covered closely with a glass, will be certain to wither and fall off; if there will be but very slender chance of the stock's completing a union; it is performed as follows: having provided a stock, which should always be some of the courser free kinds of the same genus of plants, and nearly of the same diameter as the shoot which is intended for inarching; cut a
thin slip from two to three inches long, about one third or something better of the whole thickness, smoothly off from each of them, in the clearest part of the stem, with a small sharp knife; a most necessary instrument for this business: the bark of each must then be fitted together in the exactest manner, at least on one side, and tied perfectly tight with good matting; they must be clayed in the same manner as usual, and kept within doors until the 9th of April, when a warm in house will encourage them a little. As a consequence liable to crack, they should, at least in dry weather, receive two or three times a-week some water from the rose of a waterpot or by means of a syringe, to preserve it in a most proper state, observe to take great care that the syringe never receive leaves etc. tied neatly round each ball of clay will prevent the water being so frequently necessary; eight or ten weeks will in general be found sufficient time for them to unite; at all events, by that time they may be partially separated from the parent plant, by cutting the inarched shoots better than half-way through; and then, if better, they may be fully disengaged, and both the parent and the young may be watched. Towards the 36th week, the branches will be entirely cut off and placed in a shady part of the house, where they must be kept moderately syringed as before, and some additional shade given, according to the state of the weather, for two or three weeks; during which time they may be united, and the top of the stock cut off in a neat manner; and another unnecessary part of the branch, unless the acorn be cut, burned, and cut therefrom off; these fresh wounds may have sufficient time to become properly healed, which they will in a few weeks.

In this manner, Cushing succeeded with myrtus piminate; and other plants allied to it may be propagated in the same manner, with particular, much less difficulty than to multiply by any other means; and also many other plants of the same description upon their kind.

6688. General culture. To attain a respectable degree of perfection in the culture of tropical plants, Cushing observes, the principal objects to which one should direct his attention, are assiduity in keeping up the stock by propagation; a careful nicety in potting, and shifting in the proper season; a regularity in watering when requisite; a thorough knowledge of the temperature necessary to be kept in the house; and a steady attention to the cleanliness and habits of the plants in general. The business of shifting, or refreshing the roots of plants with earth properly prepared for that purpose, and transplanting them into larger pots than they before occupied, is one of the most necessary operations required to keep them in a good state of growth. The quantity of earth contained in a flowerpot being in comparison so small to that which is requisite to the support of the generality of plants, it must be supposed that unless it is changed or augmented in due season, they will soon exhaust every particle of vegetative matter contained therein, though frequently assisted by proper water, which doubtless contains a large portion of the food of vegetables; the consequence of which is, to the weaker-growing and tender kinds, that its salts being dissolved, and the sandy particles which kept in it a free open state washed away by the frequent and long continued ablations, it becomes, in the case of ill drained pots for seeds, sour and coagulated; and the plant being no longer able to draw its proper nourishment from it, must inevitably decline, and at last becomes a nuisance to the collection, by breeding insects and filthiness: to the stronger sorts, though, in a different manner, it will be no less pernicious, by starving them, and thereby occasioning them to dwindle into naked stems, and awkward unsightly forms.

6689. The season most proper for shifting hot-house plants is about the middle or end of April; if done earlier (though some hot-house plants may be said to be in a state of growth for the greater part of the year) the generality of them will be found dormant; and therefore will not have the power to establish themselves sufficiently in the fresh earth to prevent a great part of their leaves falling off, and the plant withering; it will remain during a sickly appearance; and it is certain, that they will be in a vigorous state, and it will require infinite care, and increase of labor to keep them properly shaded, else the intense influence of the sun on them, at an advanced season, will have, though a different cause, nearly the same effect; and reduce them to fully as disagreeable a state as in the former case. Let it be observed, that after they have been set out in the fresh earth, before the first hard frosts of the season come in motion, and not having a top full of young tender leaves to support, they soon find their way into the fresh mould; the plants, by being thus taken in time, and when done, placed in a brisk bottom heat to assist them, will in the space of three or four days at farthest be well recovered, and in general, able to support themselves against the strongest rays we may reasonably expect at that season, without much danger to their leaves.

6690. Operation of shifting. Being fully prepared for the removal of the plants, let a part of them be taken to the potting-shed together, that they may be no longer than necessary out of the store; and while these are shifting, the remainder may be taken out of the tan, and set on any of the shelves or benches that are over the flues, so as to allow sufficient room to have it forked up and turned; and should it be sunk considerably below the desired height, some fresh well dried tan should be added, and mixed well. After the turting, when the pots are set out, let it be carefully attended to, that they are not conveniently and regularly set on the surface when shifted. In shifting the plant, the greatest nicety should be used not to injure the roots; because, if the roots, from a multiplicity of wounds, (which are not healed from them,) once become cankered, or contaminated in any manner, the branches must also be expected to suffer and decay.

6691. An old but erroneous practice followed by many, is that of paring off the best part of the roots with a knife; that is, the tips or ends of the fibres, which are undoubtedly the active agents in collecting the food for the stem, &c. then, without ever loosening the remaining part of the ball, set in the new pot with a little fresh earth thrown loosely about it: as a matter of course, they think it must then be completely drenched or flooded from the waterpot; and lastly, to crown the whole, perhaps set it immediately over a fire of charcoal. If they only thought that always reduced the roots, it is impossible they could ever conceive them to be in a state fit to undergo such treatment with any kind of advantage; but it is the misfortune of many, who will not habituate to undertake the care of tender and curious plants, as a matter easily understood, yet will not take the trouble of looking into the book, or other directions, to follow those precepts correctly. They may have before seen practised on the hardiest geraniums or myrtles. Though the method may not seem to hurt some few kinds of strong free-growing plants; yet it never can be allowed as a proper mode of treatment for all plants indiscriminately, because they may happen to have a good deal of roots or fibres; indeed Braconier has been observed an any part this particular part of the system of managemant which some so blindly follow. There are instances, however, wherein a knife is necessary to the roots as well as the branches, viz. when they become rotten or otherwise contaminated; and also to such as are propagated by cuttings of the roots, as most species of geranium may be, some mimosa also, and indeed any that are observed to produce suckers: in all which cases they should be taken off with precision, and a sufficiency left to support the parent, if considered worth preserving.
In turning the plant carefully out of its pot, observe if the roots have perforated it in any part, so as to render it impossible to part them without breaking the one, or lacerating the other; in which case cut the union with a razor or knife. If all of roots have been forced out, let the broken tiles, or whatever substance may have been used as draining, be carefully picked out without tearing off the roots that may have grown amongst them; also any calcified or mossy substance on the surface of the base of the roots. Then, lay the whole in sawdust or other clean material in among the fibres; let the whole be pressed moderately light, but not so as to open the pores of the earth without cracking the roots; shake off any loose earth, and having a proper sized pot, ready prepared, put in a quantity of the fresh mould sufficient to raise the crown of the roots above the rim; then set the plant carefully back into the pot, and add more sawdust or other clean material, still keeping the soil light and loose in among the fibres; and thus the roots will be properly set in place. After doing this, the plant may be watered, and a smooth surface left upon the head, with the rim, as it will settle to a proper depth with watering, and smooth the whole off neatly with the hand.

Two or three assistants will be found necessary, where there is much of this work to be done; one to care for the flowers, and other hiding-places; the other to set the plants and to clean from insects, &c. any plants that may happen to stand in need before shifted; and in tucking them up properly to their sticks afterwards: new sticks should be had at least once a-year, to hot-house plants in particular; as the old ones very often harbor more or less of the several pestiferous insects which infest the house. When these plants are set on a level spot together, and moderately watered with a fine-rose pot, held at a distance above their tops so as to give the leaves a good rinsing; but observe to give no more water than is sufficient to settle the fresh mould to the roots, and by no means to slush the surface that puddled appearance, so very disagreeable to those who observe in departmental places where neatness should be the uniform and leading principle. Having thus finished the first division, let them be immediately taken to the stove, to be set on the fresh-turned tan for the present, and those that remained there, taken to the shed and treated and shifted in the same manner as the others. It will be found beneficial to partially prune the roots; and if the plants have lost half its depth loosely into the tan, to avoid the danger that attends too violent a heat arising in the pot; which is frequently the case, when it has been recently turned or augmented. However, there must be a pretty brisk fire-heat kept up in the house, until the plants recover from their inactive state, the unavoidable result of the root's being so recently disturbed. They will be much benefited at this time by a moderate use of the hand-syringe, in the morning before the sun has begun to act upon them; also by raising a strong steam in the house, to be done by throwing water on the tops and the sides, and in the floors. Allow the plants to remain so, from the time they are taken from the water-pot; as over watering is very pernicious to plants in general, and at no time is it more particularly so, than when they have been lately shifted. However this must unavoidably depend on the judgment of him in whose care they are placed; as some of them will require considerably more than others. Too great a heat is even dangerous in the young plants; and these should be at first kept in the tan up to the rim; but observe that it is not left scattered on the surface of the pots, as it would give the work an extremely slovenly appearance; a few inches of clean sawdust laid over the tan, gives a clean and heat appearance, which, in most gardens, is a particularly essential part of the curator's art. It is well to note here, that in drying the heat, as they are really plunged, and the remaining ones regulated on the different benches or shelves; let the place be well cleaned out, when little more will be necessary for a few weeks than watering when requisite, squirting, steaming, and attention to the department. Nothing should be left undone this season, or the plants stand in a heat of sixty degrees. If it is kept much lower, it will considerably retard the plants in recovering their vigor; if many degrees higher, the free-growing kinds will soon over-top, and materially injure the weak and more tardy sorts unless prevented; besides themselves becoming unsightly, the consequence of being drawn off forced into long weak ungraceful stems.

Insects. As the heat increases with the advancing season, the different species of insects to which these departments are liable, will multiply incredibly. Those which seem to make the greatest havoc amongst plants in the hot-house, are, the green fly, the thrips, the mealy white bug, the great scaly bug, the small scale, or the pine-bug, and the red spider, which, although the smallest, is by far the most destructive of any of the species that exist in these departments.

For the fly and thrips, there is no process which seems to take so much effect on them, as a strong fumigation of tobacco; repeated twice or thrice, according to the strength the insects may have attained.

For the bugs, there is none of the several expensive methods mentioned in different authors so effectual, as simply picking them off; this may be said to be tedious, but it has a little in its behalf; besides, that the plants are in no manner disfigured by the opium within, but the less establish being observed in looking for them, examining plant by plant, and leaf by leaf, from top to bottom, and also any incisions or cracks that may be in the bark of the stem, &c. there will be a constant and tiresome employment; on the contrary, if regularly done, one operation will be of more service than five, if executed in a careless inattentive manner. As each individual plant is picked, it should be carefully washed with a strong liquimony of soft soap and water, which will have a powerful effect on their eggs, which are in general sufficiently small to elude the eye, or perhaps so situated within the young buds that they escape being noticed; for during the growth, the great advantage is, that the flesh will, however, penetrate into these secret holes, and in general be fully adequate to their destruction.

When the plants are out of the house in summer, every part of them should be well washed with strong soap-suds, in which a little of the same tobacco, as used for fumigating, has been infused; in particular all the limbs of the plants: if the saps or sap-guard is well dried, it is not necessary to observe this, but in the house if the sap remains in the leaves the insect from extending its slender web from leaf to leaf, and thus checks its progress; while the syringe, by a superior force, breaks the ligaments of those already made, and in most instances washes the insects to the ground; where, although it may recover its fall for the first or second application, it is in the end sure to fail; however, if you substitute for it a second application, for the great length of time necessary, for large horizontal leaves, which serve them as citadels against the attacks of the water; but here they will soon betray themselves, by extracting the fluid substance of the leaf for their support, in consequence of which it loses its verdure and becomes covered with moss. This, when found, should be picked off, and taken out of the house immediately; for if left anywhere among the plants, the opium when it comes down will destroy themselves on others. If they happen to be discovered before the leaf has lost its beauty, they may be rubbed off with the hand on a sheet of paper, and expelled the premises. If at any time the quantity
of water necessary to be used in these operations, should occasion the earth to become over-wet, in those pots particularly which are plunged in the bark-bed, the syringing must be omitted, and use made of the tractor, or air, until they again become too dry. When the sun acts freely upon the plants, lest their leaves become in consequence disfigured. For the water forms itself into little spherules, the surfaces of which collect the rays of the sun in a greater or less degree according to their convexity; and thereby the leaves are disfigured by being burned in the focus of each spherule.

6700. Summer treatment. As the season advances, it will become necessary to admit a reasonable portion of air on all fine sunny days; and also to decrease the strength of the fires at night: but in these particulars, the only criterion to be guided by, are experience and observations on the weather, the variations in which render it utterly impossible to lay down any certain rule to act by, further than the admonitions of the thermometer; observing to keep it pretty near to sixty degrees. About the beginning or middle of May at farthest, fires may be omitted entirely; as the natural heat of the season united to that of the bark-bed, will in general be found sufficient to keep the mercury up to the above-mentioned point.

6701. Towards the latter end of June, the plants by this treatment will generally be in a very luxuriant free state of growth; it will be therefore requisite to raise the pots quite out of the tan-bed, to check and harden them a little, so as to be able to bear the air of the green-house for a few weeks, which will be of considerable advantage to them the ensuing winter. Should any of them remain of a sickly appearance, and that a few may be in that state, in large collections, must be reasonably expected, or any particular tender sorts among them, they must be removed to a separate house, as already hinted, where the sun being previously forked from the frame, will be otherwise prepared for their reception, they must be immediately plunged, if no such house is convenient, a couple of beds framed of well-prepared dung, will answer nearly as well for this purpose; having nine or ten inches of rotten tan or sawdust spread regularly over the bed within the frame, in which the pots are to be plunged.

6702. As soon as the plants have been plunged, a few days are required, that the steam and violent heat may have sufficient time to evaporate. At the expiration of five or six days, however, the plants in their pots may be set on the surface; where they should remain a little time longer without being plunged; but particular care is necessary that the frame at this time may not be kept too close: air will be requisite to avoid that heat too great; as a mean to avoid this, give plenty of air in the daytime, and also a little at night, with a mat hung before it to prevent the sharp air entering into the frame. When the heat of the bed has attained a proper temperature, so that there may be no danger of the roots being burnt or otherwise injured, let the plants be plunged, and afterwards a few days set in the frame; the whole bringing up the house: only observing to keep those that are in a weak state rather dry; as nothing can be more injurious to a sickly plant or to too much moisture, by reason of its inability to imbibe the usual quantity through want of proper connexions, which remain set to be evaporated; and also an increase of fresh air on all fine days; and also (the pots being quite out of the tan) they will require a greater portion of water than has been usually given them when plunged.

6703. As soon as the weather becomes settled, and the night perfectly free from all chilliness and frost, which is seldom much before the middle of July, the plants may with safety be removed from the green-house; and set regularly on the benches lately occupied by the green-house plants; which they will ornament very much, during the time the latter are set in clumps in the open air. The stove may in this interval be furnished with a few of each of the different tender annuals, to give it something of a gay lively appearance. They will likewise in some measure serve as a kind of natural trap for the spider, &c.; as they will, should there be any of them left in the house, immediately attack the soft tender leaves of these plants, in which case, as soon as they are observed to be collected in force upon them, it should be removed to a safer place, where it can be substiututed in its room; this practice will contribute towards subduing this formidable enemy, so that, combined with other exertions, by the time it becomes necessary to have the hot-house plants reinstated in the bark-bed, the house should be pretty free from them. These being now in the green-house, will require more attention to preserve them from the dryness of the air, than verdure, so little more, than by admitting air only on fine days; thus to exclude any chilling or strong winds that may happen to prevail, which would occasion the leaves to contract a languid yellowish appearance; however, in course of a week or ten days, they will be able to withstand any weather that may in reason be expected at this season. The air should be kept as cool as is consistent with the interior of the house; they seem to bear more the violent, than the cold cold

6704. The removal of insects, weeds, and dead leaves is the principal care they will require now for about a month or so, also casually tying up any that may want it, and watering; in which last article, it must be observed, that as they now stand upon dry boards, and the air acting freely on every side of the pot, they must consequently be allowed an increase of water, to counterbalance its effect. The evening is the most proper time for watering at this season, as well as syringing, particularly when dry and warm; for if administered in the morning, the rising heat of the sun exalts it, before it has time to descend to the lower roots; and unless replenished frequently in course of the succeeding day, they are liable to much injury, by being left in an exhausted state until the following morning, and which, it is probable, may not prove more fortunate; whereas, if administered in the evening, it refreshes them after the preceding day’s drought, and affords them sufficient time to permeate the roots, before the night

6705. By thus setting the plants in the green-house, it tends to prevent the increase of insects; also their too luxuriant growth during the summer months; and by hardening and ripening the wood, renders the plants more fit for the firm, and the more likely to bloom which it is in these ornamental plants, the principal object of the cultivator, besides that they are not so liable to be injured by the severities of the succeeding winter.

6706. Autumn treatment. Towards the latter end of August the natural heat of the atmosphere will be on the decline; therefore, except on particular fine days, when a small portion of air may be given, the lights must be kept perfectly close; but more especially so at night: as we have frequently at this season heavy chilling dew, and are also often surprised with unexpected showers of rain or hail; to admit either of which might be very injurious to the plants; however, by shutting up the house before the sun has withdrawn its influence entirely from it, and thereby warming the enclosed air, they may safely stand here some days longer.
WOODY BARK-STOVE PLANTS.

6707. As soon as the month of December commences, it is time to think of getting the stoves ready for the winter season; a quantity of fresh tan should be provided, sufficient to raise the temperature of all the pots, and other planters, to a sufficient degree, to keep them in a healthy state, and to prevent the plants from being injured, which would be very likely to happen, unless the temperature of the house is kept constant in all respects, and the walls well dusted; an operation necessary to be done every year in these departments, where strong fires are kept for such a length of time; likewise, let the old tan be sifted in the common way, with a pretty coarse sieve or riddle; some gardeners throw it entirely away, but the part sifted being mixed with the new, prevents its being too dry, and the tan, when first put in the pot, tends to produce a dry heat; the tan, in the other than the one in which it naturally would if used by itself; as it would be very violent at first, and consequently, like all other things that are worked up above their pitch, liable to be sooner exhausted in the tans, in the first frost.

6708. Having sifted and got away all the refuse of the old tan, let the fresh, if well dried, be immediately carried in, and both well mixed together in the pot; still adding, until the bed is raised to the proper height; this done, let the wood and glass-work, kirbs, passages, &c., in short, every part of the house be diligently examined, and all those things removed to prevent any heat in the other than it naturally would if used by itself; as it would be very violent at first, and consequently, like all other things that are worked up above their pitch, liable to be sooner exhausted in the tans, in the first frost.

6709. The pots must not be plunged in the tan at first; as well on account of the danger of the violent heat injuring the roots, as because this early plunging might start them into a fresh growth; which, at this late season, would not be at all to their advantage. They must, therefore, be set on the surface of the tan in regular order, when they stand out, as well as plunged in it, in this particular by the state of the atmosphere abroad, as well as the internal temperature of the heat in the pit; by the first week in October, the heat of the external air will be considerably abated, and that in the pits sufficiently moderate. The time for plunging being fixed on, observe to have it done in the moisture of the tan. As the back or the sides of the pit are dried, the lighter ones of the tans, and the lower ones of the pits, in regular order, according to the form of the house, and the mode of arrangement adopted; if sawdust is used, it will contribute much to their cleanliness, and also make a more agreeable appearance than the tan. All being set to rights, and the passages, &c. swept clean, give the plants a good draught of fresh air and sun; when they have acquired the warmth of the room, they may have a fresh draught of fresh air for a period to warm their stems, and then place them in the sun, to keep them from being injured by it: should it be done in the evening, the air in the house will undoubtedly get chilled, especially in frosty weather. It is even necessary that the water used for this purpose should be nearly of the same temperature as the air in the house.

6710. About the middle of October, it will be necessary to add a little fire-heat at night, beginning with slow fires at first, and gradually increasing them as the severities of the weather increase. Although a circulation of fresh air is at all times requisite to the health of plants, yet the heat of the external atmosphere will at this season be so much diminished, that it will not be found convenient to admit it in any considerable quantity; in fact, none should be given, except on particular fine days, when the front or end lights may be opened a few inches. They should be shut early in the day, seldom permitting them to be opened; the sun, by revolving the sun, will soon begin to produce a very severe frost; and seeing that the chill of the night commences; even this little indulgence cannot be allowed from about the end of October until the beginning of April; as the strong cold winds which generally blow during the winter months find of themselves but too many entrances.

6711. When plunging in the last of December, it is perhaps longer; being guided in this particular by the state of the atmosphere abroad, as well as the internal temperature of the heat in the pit: by the first week in October, the heat of the external air will be considerably abated, and that in the pits sufficiently moderate. The time for plunging being fixed on, observe to have it done in the moisture of the tan. As the back or the sides of the pit are dried, the lighter ones of the tans, and the lower ones of the pits, in regular order, according to the form of the house, and the mode of arrangement adopted; if sawdust is used, it will contribute much to their cleanliness, and also make a more agreeable appearance than the tan. All being set to rights, and the passages, &c. swept clean, give the plants a good draught of fresh air and sun; when they have acquired the warmth of the room, they may have a fresh draught of fresh air for a period to warm their stems, and then place them in the sun, to keep them from being injured by it: should it be done in the evening, the air in the house will undoubtedly get chilled, especially in frosty weather. It is even necessary that the water used for this purpose should be nearly of the same temperature as the air in the house.

6712. Winter treatment. At the middle or end of December, it will be necessary to have the tan in the pit turned, and renovated with a little fresh well dried bark to en- liven the heat, as the severest part of the season is still to be expected; however, in performing this work, great care is required that the plants are not chilled or injured by being removed out of the tan-bed at this cold season; therefore, the mildest weather must be chosen for performing this operation. The pit being cleared, immediately proceed to turn over and mix the old and new tan well together, in which, as soon as it is completed and levelled flit to receive the pots, they may be plunged without delay; as there is not that certain danger of a burning heat ascending now as in the summer months, in which season the powerful action of the sun occasions it to ascend more violently.

6713. Plunging the pots. Should it not be convenient to have the whole plunged the same day, those left will require to be set on the surface of the tan during night; lest by being left near the glass, or extreme parts of the house, they might be severely injured ere the morning by the cold air; as it is therefore advisable, at the end of the day, to withdraw all the plants out of the tan, and when not plunged, they may be plunged the next or following day at farthest: it will be also requisite to keep a pretty brisk fire-heat in the house, while the plants are out of the tan, and until the bottom heat in the pit begins sufficiently strong; otherwise, the plants will not be considered as animal; and lose many of their leaves; and the pots in these cases not much checked at this season. Should it happen that a series of clear fine weather follows this operation, the action of the sun may possibly occasion the heat to rise rather violent in course of a few days after being renewed; to this particular attention must be paid, and if any such symptom should appear, it must be immediately stopped by lifting the pots of these places, and throwing into the holes a small quantity of the surface tan; on which the pots may be again set in a loose manner; thus, by permitting the heat to pass freely off by the sides of the pots, it prevents its burning the earth or roots, which would be certain death to the plants; when its violence has subsided, let the pot be levelled, and pots properly replenished; but unless the weather, as already noticed, happens to be particularly fair, all likelihood this labor will not be encountered.
6714. Watering and cleaning. They will require from this time until about the beginning of March, nothing more than the usual care of watering when necessary, and cleaning them from all dirt or insects as soon as they appear; also to keep the temperature of the enclosed air as near to its regular pitch as possible: to assist in compassing this object, when the weather sets in severe, it will be proper to use either shutters of canvas or bass mats to cover all the lowest parts of the house; and in particular those at the greatest distance from the entrance of the fires every night; otherwise the frost will easily enter these remote parts, and chill the air through the whole house; the consequence of which may be very injurious: on the other hand, if these precautions are not attended to, there will be a necessity of keeping up a very strong fire, heat, which will likewise be attended with pernicious effects.

6715. Insects. It is in these intervals that that destructive insect the red spider makes the most rapid progress, on account of the necessity there exists of keeping the houses close, and supporting a dry warm air, both of which circumstances are particularly congenial to its nature; therefore on all fine mild mornings, observe to raise a powerful steam in the house as already directed; by the frequent repetition of which there will be a possibility of keeping them under control.

6716. Refreshing the bark-bed. As the internal strength and heat of the tan will now be much on the decline, in consequence of the length of time it has been in use, it will be requisite to turn it more frequently, so that about the beginning of March, it should be again stirred to at least half its depth; which will afford a temperate heat, until the time in which the plants are usually shifted, when it is generally renewed. Some gardeners make it a practice to have merely the upper half of their tan-pits stirred at any time throughout the year, when the heat happens to be on the decline; this is certainly a very proper method where there is plenty of time and hands to perform it; as there is no danger of a burning heat arising; but it requires to be done so much the oftener, such heat seldom lasting above a month or six weeks; it consequently will not answer where these conveniences are not to be had. The plants being regulated in proper order as before, let them have the usual treatment until the time of shifting. (Exotic Gard. p. 70.)

6718. The propagation and culture adopted for green-house climbers, is equally so for those of the bark stoves, the difference of temperature being taken into consideration. (See 6201. and 6253.)

Sect. III. Bulbous-rooted Bark-stove Plants.

6719. All bulbous-rooted stope plants may, no doubt, be kept in the dry-stove; but if it is wished that they should flower in any degree of perfection, they must be plunged in the bark-bed, when newly planted. The same remark will apply indeed to most of the dry-stove bulbs.

6721. Propagation and culture. Being all herbaceous plants they are to be propagated as these generally are: some are raised from seeds, which in general should be sown as soon as ripe, and the pots plunged in shallow water; when the plants come up, they may be transplanted into other pots, and shifted as they advance in growth. Some of our varieties will radially take root in the same season. Instead of being kept in pots, the plants may be inserted in a bed of earth on the bottom of the aquarium. The most beautiful of the exotic aquatic, are the nymphees and nelumbiums: these, with other genera, have been cultivated to a high degree of perfection by Kent, who, instead of a regular aquarium, uses pans and small cisterns, plunged in hot-beds. Where a regular aquarium is not formed to be heated by flues (figs. 578, 579.) we should suggest the idea of a cistern (fig. 622,) to be placed on the sill in the open air. In the season for forcing the nymphees commences, it may be surmounted by a hot-bed frame of the same diameter, and surrounded by lines of cloths. By this means any required degree of heat might be produced pururing the flowering season, and if it were desired to continue any of the plants in a growing state during winter, the linings and frame could be covered with sacking, the plants might be removed to a reserve-aquarium, in the stove or propagation-house.

6728. Nymphaes, Nymphaea, and Euryale Ferox (an annual, with singularly constructed leaves, often of thirty inches diameter), Kent has proved to thrive best in a close. Nymphaes requires only to be fresh potted in spring, and placed in a pan in a hot-bed, where it will flower the whole summer. The nymphees having tuborous roots, he keeps, through the winter, in small pots (sixties), in a dormant state, in a small trough of water in the stove. Early in April, he prepares them for their summer culture, by placing these in small wooden cisterns, two feet long, fourteen inches wide, and six inches deep, and then placing them in any cucumber ormelon frames which may be then in use. In about a fortnight or three weeks a number of offsets or runners will be thrown from the bulbs. These are then separated and put into small pots; and in the course of ten or twelve days a strong plant of each species is selected, and placed in pots for flowering purposes. Under aquatics, especially the nymphees, are potted in a light frame, thirteen feet long, and six feet broad; instead of five feet, and above the ground, four feet; which is filled with tan. I have four wooden cisterns, lined with lead, four feet long, two feet six inches wide, and fifteen inches deep: they are plunged in the tan, and filled with strong rich loam, about two inches deep. The bottom part of which is rammed down with gravel, and one or two in each, according to their habit of growth. The cisterns are then filled with water by degrees. As the plants advance in size, they must be replenished and cleared from concreus as often as necessary; and if the plants are occasionally watered over their leaves, from a watering-pot, through a rose, their vigor will be greatly increased. It is important to keep them in a constant state of growth: for if checked, they will form bulbs, and grow no more during the season. This will be caused by cold; but this year (1817), the heat in June produced the effect, although they were shaded from the sun's rays by matting, and the lights considerably raised. Where dung is used, there is like danger, from its heating. After being planted out, they will show flowers in the course of a month, and some of them will continue blooming through the season. As soon as the plants have done flowering, and perfected their seeds, they disappear, and form bulbs in the mud. These, in the month of October, I put into small pots (sixty to the cast), and place them in a bed of water, in the hot-school, where, in a short time, the seeds are most likely to vegetate, if sown at the same time, and treated in the same manner. Nymphaea carnea will flower in the stone; but not so freely as in the frame. Nymphaea stellata seeds freely, but the root does not easily divide; indeed it is best grown, when treated as an annual. Euryale ferox does well under similar treatment to that of the nymphees; its seed should be sown about Christmas, and kept in the cistern of the stove. (Hort. Trans. iii. 36.)

6727. Nelumbium Speciosum "is easily raised from seed, which will retain its vegetative power for forty years, and with every advantage, in a fair season, produce blossom the first summer. It is generally grown in large tubs, with a few inches depth of water over the surface of the mould, placed in the tan-bed of the stove. By these means, I raised a fine plant last year: the seed was sown in May, and threw up several flower-buds, which did not come to perfection, but most probably would have done so, had the seed been sown since the spring. The last described was of about twelve inches diameter; but the plant went off in the winter, notwithstanding it was treated in the manner hitherto found the most successful; which has been, to allow the tub to remain in the tan, and become nearly dry, giving it no more water than the other plants in the same place. I have found the same results when they are grown in the pans in the house for food; but whether fibres of it are the parents of the ensuing crop, or the pots are replenished by seedlings, does not appear. Both are probable, as the roots, which have been kept nearly dry in our hot-houses, if but a very small piece has remained alive, have become vigorous blooming plants, as well as those from seed. (Hort. Trans. iii. 36.)

</table>

6731. Propagation and culture. No plants are more easily propagated than those enumerated. In respect to culture, they may for the most part be considered as marsh or bog plants, for even the sugar-cane (Saccharum ofcinarium) and ginger (Zingiber officinales) are found in a wild state by rivers and in moist woods, and thrive best in the stove when their roots are liberally supplied with water.

Sect. VIII. Selections of Bark-stove Plants for particular Purposes.

6732. Selections of bark-stove plants for particular purposes can be but few. A collection may be made of such as are or have been most used in the arts; of curious or botanists' species; of such as are highly odoriferous, as asclepias, bignonia, elerodendron; or night-smelling, as cestrum nocturnum, cactus grandiflorus; of palms, as of the sagu-palm (Cyanus), of the cocoa-nut (Cocos), of the date-palm, (Phanix) &c; or of any of the natural
orders of such rare sorts as have not yet flowered. The following are some of the most remarkable of the economical tropical plants used either in their native countries or imported into this country.

Some minds relish nothing that is not either immediately useful, or has some relation to utility: to such the foregoing list will be of some value as pointing out plants of great importance to mankind in other climates, with the number of young persons that annually leave our country to pass great part of their lives in them, it is desirable those plants should be known here also; and hence a rational object for the patriot, who has wealth and leisure, to display them in a conservatory attached to his castle, or palace, (Fig. 623.) of suitable elevation and extent.

6733. In selections of rare or curious plants, or such as are sought after chiefly by botanists, the palms, the air plants, and the exotic ferns will be included; and on the culture of these, we shall select some remarks from the Horticultural Transactions.

6734. The palms are a natural order of plants of great interest by their utility, both as fruit-trees, and as supplying other products; and of much grandeur of appearance. The cocoa, sago, and date palms are well known; upwards of fifty other species have been introduced into this country, and are to be found chiefly at Messrs. Lodgdes. A number more remain to be procured, of which the dome-palm (Fig. 624.) is one of the most remarkable, being the only palm known to have a branched trunk like other trees.

6736. Parasitic stone plants. Maria Graham (Letters from India) remarks, that she saw many of these flourishing in great luxuriance on the rough trunks of palms in the Calcutta botanic garden. At Kew, Spring Grove, and in the garden of the Horticultural Society, they have been

---
generally grown in rough tan, closely pressed together in small pots or baskets, and suspended from the roof of the hot-house. Messrs. Loddiges have established some specimens on the trunks of palms in a natural manner, as the Honorable and late Mr. Loddiges have equally successful. "I am informed," he says, "by a friend at Cutcalta, that he cultivated with great ease, all the dendrobia aerides, and other parasitical plants, by tying them, with twine, to the stem of a tree, or to the under-side of a branch, and placing above them a pot of water with a hole at the bottom through which a strip of tin was introduced, nearly the same manner as is used to convey gradually and continually conducted to the upper part of the parasitical plant, which requires to be constantly moist and shaded; and that a tree with smooth bark answered the purpose best. He mentions particularly, that he produced, by this method, more flowers, from one to two feet long, and it appears likely to thrive with me under the same treatment. I had previously found no difficulty in establishing epidendra on the stems of trees in the store, by cutting a notch in the bark and inserting the plant like a graft, and tying moss about it to support it, till the young roots had attached themselves to the bark; but I want more of sufficient moisture, they have not made much progress, or flowered with me. I have now adopted the above-mentioned mode of irrigating them, with full confidence that it will succeed in our stores, as well as does at Calcutta; and very soon after its application to a sickly epipendron, growing on the stem of sternula balanghas, vigorous young fibres began to sprout from it on all sides. I am very much inclined to think, that most of such plants would attach themselves to the sides of a porous stone or vessel, or of a dead root, if constantly irrigated, and thrive upon them as well as upon a living tree, especially if the stone or root were covered with growing moss, for I have observed the fibres of more than one sort attach themselves strongly to the outside of the pot in which they are planted; and I conceive that they might be beautifully cultivated, upon an ornamental cone of porous pottery, filled with water and furnished, on the outside, with niches, in which the plants might be fixed, with a little moss or peat to promote their growth in the first instance. I have found the parasitical plants in danger of perishing, from want of moisture, on a deciduous tree, during its season of inactivity, but that deficiency would probably be removed by constant irrigation. The nearest and most convenient vessels for that purpose, perhaps, would be little tubs, such as are used for artichokes, which might be fixed in a large vase, or tied to a piece of string, of which one end is twisted round, or at least in contact with the plant, and the other inserted into a phial of water, will also be found to convey a regular, though less plentiful supply of moisture, acting in manner of a siphon. I have used it advantageously to nourish a graft, and promote its union with the stock. For the cultivation of parasitical plants in pots, I recommend placing the pots on a back flue, in a tin tray, about two inches deep, and half filled with wet sand, giving an abundant supply of water, but not sufficient to produce rottenness by its stagnation. I find the growth of crinums, which also like a moist heat, to be prodigiously rapid with that treatment; I should suggest a mixture of porous stones, or bits of earth-watered tan, or such beds as are used for moss-planting, and contain a tolerable moisture, to the pot, as preferable, for parasitical plants, to the loam which some of our books have recommended." (Hort. Trans. iv. 243.) All these parasites are included under the natural order of Orchideae are of herbaceous habits, and readily propagated by suckers or cuttings.

6737. The Raaffisia Arnoldi is the most extraordinary parasite known to botanists. It was discovered by the late Dr. Arnold, in Sumatra, in 1818, in a jungle of thicket, growing close to the ground under the bushes, and attached to the roots of a species of cissus or vites. The plant consists of the flower only, having neither leaves, branches, or roots; the flower is a yard across; the petals, which are subrotund, being twelve inches from the base to the apex, and it being about a foot from the insertion of the one petal to the opposite one; the petals are from a fourth to three fourths of an inch thick, and the nectarium, it is supposed, would hold twelve pints. It appears to take its origin in some crack or hollow of the stem, and soon shows itself in the form of a round knob, which, when cut through, exhibits the infant flower enveloped in numerous bracteal sheaths, which successively open and wither away as the flower enlarges. A singular change takes place in the vessels of the root or stem on which it grows; their ramifications are multiplied, and they take a direction so as to unite with and accommodate themselves to the base of the parasite to which they convey nourishment. The general appearance of the flower is that of Stapelia, and its smell is also fetid. It is diocicious, and supposed by Brown to belong to the natural order of Asarinae. There are other species of Ordellia from flowers not above three inches in diameter. Both, it is probable, may in time be introduced. (See Lin. Trans. xii. 301.)

6738. Exotic ferns. The tree-ferns, Humboldt informs us, are of singular beauty in their native sites. Only a few species of these, as dicksonia arborescens, davallia pyxidata, pteris aculeata, &c. have been introduced. Some of the pteris, which I have observed, are propagated from seeds which generally ripen freely in this country, and such as are received from abroad generally grow, however long kept; they are also multiplied by dividing the roots. The best collection of exotic ferns is considered to be in the Liverpool garden: many of these have been raised from seed by Sir Joseph Hooker, curator, and have succeeded for about three years. One common garden-pot, four and a half inches in depth, and three and a half wide, let the bottom part, to the height of one inch, be filled with fragments of broken pots by way of drain. Over these should be spread a stratum of such soil as is commonly used for potting green-house plants, of the depth of two inches, and the remaining half inch should be filled with brown Compost earth sifted through a hair sieve, the surface being made perfectly smooth, and on this the seeds are to be scattered as evenly as possible. Care must be taken that the wind be not suffered to blow the seeds away, leaving nothing but empty capsules. The seeds being sown, no other covering is requisite than a bell-glass, which should just fit within the rim of the pot, so as to exclude all air. The pot is then to be kept in a pan always half full of water, and set in a shady part of the store or hot-house, being always regularly watered as above directed. When the young plants have acquired their second leaf, it is proper to give them a little air by placing a small piece of wood on the glass, at one side. In about three weeks the glass may be entirely removed. (Hort. Trans. iii. 398.)

6739. The seeds come up in two or three months, and the plants flower the following year. It is not known how long these seeds retain their vegetative quality, but two plants of acrostichum colonelnum were raised from seeds brought from a specimen of that fern in the herbarium of Foster, supposed to be near fifty years old. But the same success did not attend similar attempts with any other specimens from this herbarium. The soil for ferns should be of a soft fine texture to suit the very small fibres of their roots; it requires also to be kept constantly moist in imitation of the native habitations of these plants; which is generally under the shade of trees or rocks. Hence also they may be set in dark parts of the stoves where nothing else will thrive.
**Sect. IX. Selection of Dry and Bark-stove Plants, for such as have only one Hol-house to contain them.**

*Tectona grandis*, *Vinca rosea*, *Volkameria acalis*

**CHAP. XV.**

6741. Our catalogue of monthly ornamental productions extends only to a few of the more generally known flowering plants and trees; what respects the hot-house department is to be understood as referring to flower-gardens, which contain at least a bark-stove, a dry-stove, one or more green-houses, and an adequate number of reserve-pits and frames. Those plants are marked (**) which may be produced from a small garden, where there is a green-house, fixed-pit, and hot-beds; not in any quantity, but sufficiently to keep up a hope and a fear for every month. The keeping up of this sort of hope and fear is much more conducive to the sort of success or interest which those who have small gardens expect to derive from them, than a grand display of two or three species of flowers, occurring only twice in the year.

**JANUARY.**

**FLOWER-GARDEN.**

*The crocus, tulip, and some alliums, beginning to emerge from the ground. If mild weather, perhaps some choice plant in flower, as the Christmas rose, daisy*, but generally no flower is to be seen at this season.*

**SHRUBBERY.**

*Evergreens display themselves to ad- vantage, especially the holly* with its coral berries. *Calycanthus preecha, red and white, and lirretusa* in flower.

**FEBRUARY.**

*The snowdrop*, *Christmas rose*, and *winter aconite*, in flower; the *cro- cus*, *cornel*, and other berries fast advancing, if the weather be favorable.*

**MARCH.**

*Among florists' flowers, the crocus*, *scilla*, *some hyacinths and crown- imperial*, and also the primrose and *polyanthus are in bloom in the latter half of the month; saxifrage oppositifolia* among the alpines; and *viola odorata* in a warm border, or on rock-work.*

**APRIL.**

*Most of the wild fruit-trees, as *crab*, *pears*, *cherries*, and their allied species, are now in flower: most of the *wells*, *birches*, *elms*, and oaks, show their catkins. Among shrub-bery, the *honeysuckle*, *some rosinia*, *andromeda*, *daphne*, *ericus*, and *zanthoxylon*, are in flower.*

**MAY.**

*The horse-chestnut*, *hawthorn*, *sor- bus*, *magnolias*, and *snowdrop-tree*, in great beauty. Among the *American shrubs, several species of *magnolia*, *azalea*, *keiana*, *andromeda*, *and among common shrubs, the *lilac*, *spirax*, *guelder-rose*, *honey- suckle*, *the cinnamon*, *Scotch*, *bar- net-leaved*, and *monthly roses*.*

Most of the singing birds in full note. **HOT-HOUSE DEPARTMENT.**

**In the green-house, the camellias** in full bloom, and some heaths and australasian plants.

**In the store, steletrizia**, seven species, and some other plants.

**In the green-house, camellias** and heaths in great beauty, and also some species of *oxalis*, *pontia*, &c.

**In the store, steletrizia**, and some bulbs, *nigmoretic*, &c., placed in the conservatory, plants cabinet, or drawing-room.

**In the green-house, some camellias** still in flower; numerous heaths in great beauty; also *alexis*, *lachena- lia*, *oxalis*, *some geraniums*, and above a dozen other genera.

**In the store, some cistus and bulbs**, *sandiaria grandiflora*, *pilula*, *eugenia*, and *justicia*. Forged articles as before.

**In the store, above thirty species of *eriogon*, and nearly as many of the *lilia family*, both *lachenalia*, *oxalis*, *anemia*, and various other genera in perfection.**

**In the store, dracaenas**, *bromelias*, *kamerfia*, *strepelia*, and *some bulbs* in flower.

**In the green-house, above thirty species of *eriogon*, and nearly as many of the *lilia family*, both *lachenalia*, *oxalis*, *anemia*, and various other genera in perfection.**

**In the store, physoteca decumana, pas- siflora racemosa**, and other species, *justicia*, *heliconia*, and various genera.

**In the store, physoteca decumana, pas- siflora racemosa**, and other species, *justicia*, *heliconia*, and various genera.

**In the store, Physoteca decumana, passiflora racemosa**, and other species, *justicia*, *heliconia*, and various genera.

**In the store, physoteca decumana, passiflora racemosa**, and other species, *justicia*, *heliconia*, and various genera.

**In the store, physoteca decumana, passiflora racemosa**, and other species, *justicia*, *heliconia*, and various genera.

**In the store, physoteca decumana, passiflora racemosa**, and other species, *justicia*, *heliconia*, and various genera.
FLOWER-GARDEN.

The collections of peonies and anemones not yet faded; those of ranunculuses, tritoma, siphiunum and xiphodes; and of the hardy gladiolus and amaryllis, and the tulipa, aster, campanula, veronica, and many showy herbariae, such as gentiana, astilbe, aquatics, and agrostomenia, albusana, &c.; annuals, as cromas, aquilegia, campanula, as temus, hydrocharis, potamogoton, viola, saxifraga, and various alpines.

SHRUBBERRY.

The lime, laburnum, and fringe-tree, in flower; towards the middle of the month a number of the rose, of American, andromeda, magnolia, rhododendron maximum and pericarpium, azalea, &c. Of common shrubs, cistus, bellatilithera, erica, dogwood, elder, cytisus, spirea, lonicer, &c. The great-sucker, or fern-owl (Cepheus europaeus), heard in the evening of the first week. Most fruit birds leave off singing about the end of the month.

JULY.

The florists' flowers of this month are, the pink, and carnation; the white marguerite and tyger lilies; the Brompton stock, larkspurs, lupines, and other biennials and annuals. More herbaceous plants are in flower in the first month of July, chelone, delphinium, dictamnus, gentiana, stokes, phlox, silene, salvia, veronica, saxifraga, &c. The most showy of the aquatics, azurmania, upharia, vilaxias, alisma, calla, stratiotes, myosotis, &c. are now in flower, and various alpines.

The turfis' flowers of this month are, the green-house and glass-house, campanula, anemone, heliophila, lobelia, annual stocks, and the poppies, with liliums and crocuses. Among the American species. Numerous herbaceous plants are now in flower in larque, and the first week in July, and others, as aster, various species, astilbe, aquilegia, osiriaspin, and numerous others first bloom in this month. Among the aquatics may be mentioned lobelia dortmanniana, polymon blood, and several species of potamogoton.

Aridia spinosa, some azalea, and kalmia, Lord Macartney's rose, and many other shrubs that are in flower during the greater part of this month. But the chief ornament of the shrubbbery is the fruit of the common viburnum, mogulus, oaxacana, buckeye crab, sorbus, lonicer, apple, rose, elder, &c.

Splinters, flies, and insects of all kinds, very numerous; few birds in song; but the Rosella appears about the end of the month.

Seeds are now in good flower; but American shrubs have various sorts of azalea, clethra, and magnolia, in perfection; and of select common shrubs, the hibiscus, with its numerous and beautiful varieties. The rose, the honeysuckle, yellow jasmine, clematis, spirea, and several other shrubs show in the shrubbery and roseary, during the month.

OHCTOBER.

The florists' flowers of this month are the Chinese chrysanthemum, some of the hardier of which will now flower in the open air, and the others under a glass case or in the green-house; the colchicum; autumn crocus, cyclamen europaeum, and amaryllis lutea. The principal herbaceous plants are, aster and solidago, with asphodelus altissimus, helianthus, gentiana, phlox, and asphodelus, the chief sorts.

Arbutus unedo is the only useful shrub in flower, and also, at this season, gosinda, rhamnus, baccharis, clematis, and the common ivy are also in flower.

Any spare room in the green-house is now occupied with chrysanthemums, and some dahlias raised in pots, and placed out of the reach of frost, to prolong their bloom. We have a few cistus, stokes, and geranium, still in flower.

In the store, vincia, tagelius, and a few others.

The reserve-pits in preparation for forcing bulbs and roses.

NOVEMBER AND DECEMBER.

The remains of last month in greater or less beauty, according to the weather. Few plants naturally in bloom.

The remains of last month, according to the weather. Clematis calycina; and perhaps a few plants unsubstantially in bloom.

The green-house is now filled with tender annuals, such as balsam, globose-amaranthus, coscombis, ice-plants, sensitive mimosa, &c. and probably with some of the stove plants.

In the open air, the geranium will be in prime beauty, and the cautleya, nymphaea, melaleuca, mezotrodes, and numerous other water gardens.

There are numerous stove plants now in flower, such as canthus, nicotiana, gloriosa, amaryllis, sarracantum, cactus, euphorbia, myrtus, lophenium, justicia, &c.

The reserve-hot-houses as before.

SEPTEMBER.

The florists' flowers of this month are the dahlias, which flowers also when cut, are sent to the nurserymen to be planted in the open ground in July and August; but planted in the usual way, they bloom in October. Among the bulbs there are only leucothoe amabilis, meconopsis, and scilla autumnalis; the china aster, in all its varieties, is now in perfection. Among the herbaceous perennials, aster, solidago, helianthus, gentiana, phlox, and asphodelus, are the chief sorts.

The green-house is generally returned to their winter habitation in September, and the pelargoniums, and pelargoniums, and a few other species in flower.

There are not many stove plants in flower at this season; amaryllis, passtheps, and some nuculans may be mentioned.

General supplies from the forcing-department of the reserve-garden, for decorating the plant-cabinets, conservatory, or drawing-room.

The green-house now filled with tender annuals, but excepting geranium, erica, and some perennials, not many species in flower.

The open air plants growing vigorously, but excepting geranium, erica, and a few species of pelargonium, not many species in flower.

The store, acacias, convolvulus, passtheps, and some nuculans may be mentioned.

The reserve plants in preparation for forcing bulbs and roses.

The green-house is now filled with tender annuals, such as balsam, globose-amaranthus, coscombis, ice-plants, sensitive mimosa, &c. and probably with some of the stove plants.

In the open air, the geranium will be in prime beauty, and the cautleya, nymphaea, melaleuca, mezotrodes, and numerous other water gardens.

Any spare room in the green-house is now occupied with chrysanthemums, and some dahlias raised in pots, and placed out of the reach of frost, to prolong their bloom. We have a few cistus, stokes, and geranium, still in flower.

In the store, vincia, tagelius, and a few others.

The reserve-pits in preparation for forcing bulbs and roses.

Drysandra, erica, lataeus, and camellia, about the middle of December, are now in bloom.

In the store, all the species of streptocarpus, also stapelia, stokes, and erica, and one or two other bulbs. From the forcing-department, hyacinth-sorts, larkspurs, violets, Indian pinks, pot-marguerites, and several sorts of cyclamen, montbretia, gentianas, montbretia, gentianas, monthly roses, yellow amaryllis, and other shrubs and flowers, such as sweet bells, Persian lilac, variegated crabs of different sorts, pinks, sweet williams, &c.
ARBORICULTURE.

BOOK III.

ARBORICULTURE, OR PLANTING.

6742. A tree is an object which has at all periods been held in a certain degree of admiration by mankind, from its grandeur, its beauty, and its use: a few trees have accordingly been associated with the dwellings of civilised nations in every country. The Persians, Greeks, and Romans were particularly attached to trees: some of their greatest men were proud to acknowledge that they had made plantations with their own hands; and fine specimens, whether planted by nature or art, were held sacred, or specially protected. (57.) The Romans, besides the ornamental plantations of their villas, planted occasionally for useful purposes; they had live hedges, osier plantations, and rows of poplars and elms as props for their vines. (57.) The planting of extensive tracts for timber or fuel, however, does not appear to have been practised by them, or any other people, till the beginning of the sixteenth century, when the insufficiency of the natural forests, which had hitherto supplied civilised society in England with timber and fuel, rendered planting a matter of necessity and profit. In the century succeeding, the improved practice of agriculture created a demand for hedges and strips for shelter; and the fashion of removing from castles in towns and villages, to isolated dwellings surrounded by verdant scenery, led to the extensive employment of trees both as objects of distinction and value. For these combined purposes planting is now universally practised: what relates to the effect of plantations, as parts of rural scenery, belongs to landscape-gardening; and what relates to their use and culture is the subject at present under consideration. We must however keep both objects in view, as well in contriving what shall be most profitable, as in designing what shall be most ornamental or picturesque. We shall therefore consider the uses of trees and plantations with a view both to profit and ornament; the kinds of plantations, their formation, their management, the formation of a tree-nursery, the surveying and valuing of trees and plantations, and the catalogue of timber-trees and hedge plants.

CHAP. I.

Of the Uses of Trees and Plantations, and the Profits attending their Culture.

6743. The purposes for which plantations are made, may be reduced to those which respect the actual consumption or employment of the tree or shrub individually; and those which respect their collective influence relative to surrounding objects. The first considers trees as affording timber, fuel, bark, and other products; and the second views plantations of trees as affording shelter, shade, fences, ornament, or otherwise conferring value on territory.

SECT. I. Of the Uses of Trees individually, as Objects of Consumption.

6744. A tree is employed after it has attained a certain age, bulk, or dimension, either in civil, military, or naval architecture; in the construction of machines, implements, and utensils; as fuel; or as affording tannin or dyeing matter; food or medicine for men or animals; or poison for vermin.

6745. For civil architecture the matured timber of the pine and fir tribes is in greatest demand, and foreign deal is generally preferred to British produce, as being of larger growth, and more resinous and durable in quality and texture. That which approaches the nearest to the pine and fir timber of the north is the Scotch pine (Pinus sylvestris), when grown in the north highlands, and the larch fir (Pinus larch), when grown in hilly or poor districts; resinous timber of the species indigenous in cold countries, when grown on rich soils, and in warm climates, being found deficient in durability. Oak and elm are also used in buildings, especially the former, as being of great durability and suitable for wooden bridges, breakwaters, piles in damp situations or on ground-floors, sills, wall-plates, staircases, door and window frames, sashes, &c. Elm is not much used in buildings of magnitude, as being apt to twist, and not very durable; but it makes curiously variegated floors and steps of stairs, and very good weather-boarding for sheds and agricultural buildings. Besides timber and timber-like trees for the general purposes of civil architecture, there are some departments of rural construction, as the formation of fences, drains, embankments, trellis-work, arbors, and the supporting of plants in gardens, which consume branches, spray, thinning of young plantations, and shoots even of a year's growth. Almost any species of tree may be used for these purposes; but the branches and spray of the oak, elm, and beech, the seedings of ash or larch plantations, the shoots of a few years' growth of the oak, sweet chestnut, ash, and hazel, and of one year's growth of certain species of willow are greatly preferred.

6746. For military architecture, by which we mean chiefly the outworks of fortifications, any tree is taken; but the pine and fir tribes are greatly preferred, as requiring less labor in cutting and preparing. Besides those of a timber size for constructing bridges, portals, and others of less dimensions for palisades, chevaux de frise, &c.; branches, spray, and shoots are used for fascines, and fixed works en haie, en corbeille, &c.

6747. In the architecture the oak is chiefly used. According to Marshall, "the keels are now pretty generally laid with elm or beech; and part of the upper decks of
men of war is deal: but these woods bear no proportion, in respect of the quantity used, to the oak. The timbers of a ship are principally crooked, but the planking is cut out of straight pieces. In a seventy-four gun ship, the crooked and straight pieces used are nearly equal, but the planking under water is of foreign oak: therefore, of English oak, the whole of which is crooked to straight pieces is almost two to one. Masts and yards are of deal. The blockmakers use elm, lignum vitae, box, and other hard woods. Upon the whole, it may be said, that, in the construction of a ship, oak is the only English wood made use of; and that this English oak nearly two thirds are requisite to be more or less crooked." (Planting and Rural Ornament, i. 49.)

6748. In the construction of merchant-vessels, Montech, in 1820, states, that "the out-keel commonly used is of beech or elm, and made generally of two or three trees or pieces joined together to whatever length be required. These require the same straightness as those of the ship, and are nearly the same description, but chiefly hard. Floor timbers are sometimes used of elm and beech, and are a little crooked. First crooks are a good deal crooked towards the one end, as they begin to ascend up the vessel, and are more valuable than the floor timbers, but are also used sometimes of elm and beech. Upright timbers are always made of oak, and are considerably crooked, for elm or beech is seldom put into a good vessel, except the lower part, where the vessel is always under water when light. Top timbers are also of oak, but not so valuable, as they are mostly straight. Beams go under the deck of the vessel, and are also all oak, and have but a small crook, but require trees of considerable length. Knees are always of oak, and are the most principal crooks in the vessel. The stem-piece is a very particular crook. Breast-hooks also have particular crooks. Stern-posts and windlass are straight pieces. Trees that will cut up for planking are used of as great a length as they can be got, and are the better for having a crook. The crooks of such trees are used for frames of houses, and sometimes the joints of these are used for doors, but, four planks of oak are required for one of beech or elm for this purpose." (Forester's Guide, p. 111.)

6749. Straight timber is bent to any form by the use of steam, and other improvements in ship-building; and it is probable that, in some cases, any sound rotten, if it may be employed, is in all materials the best for commercial ships. Sir A. Grant, an experienced planter, is of opinion, that "the larch will, in a short period, instead of the oak, bear the thunder of Britain on her element, the ocean." (Gen. Rep. of Scot. i. 570.) In a communication to the President of the Board of Agriculture, by Wilson, at London, dated in 1747, he states that the increase of confederated states, has introduced trees of new sorts; and that oak of only thirty-three years' growth, by this mode of combining, may be employed where trees of a hundred years old would be requisite by the old method: and he maintains, that ships so built sail faster, and are more durable. (The President, 1747, p. 190.) The larch, also, has been introduced in the construction of masts for the largest vessels, either by splicing pieces properly adapted together, or, by forming hollow masts from small timber, which, uniting strength with lightness, have advantages which solid ones do not possess. (Perring and Money on Ship-building.)

6750. In the construction of machines, the millwright's chief material is oak, beech, and crab-tree for cogs: alder, and sometimes willow, for float-boards; and fir and oak for shafts and frame-work. The waggon and cartwright uses oak and ash for bodies, axles, and spokes; elm for naves, fellies, and linings; sometimes also the softer woods for linings, as poplar, willow, lime, and horse-chestnut. The coachmaker and ploughwright use more ash than any other sort of timber. Gates are made of oak and deal, and their posts of oak or larch: the soft woods are sometimes used, but are far from being durable. Ladders are formed chiefly of deal, or of poplar and willow, as being light; pumps and water-pipes generally of elm and alder; beech and sycamore are used in making calenders and cheese-presses, &c. For all these purposes the timber must be full-grown, with some exceptions, as young or root-cut oak and ash for spokes and shafts.

6751. For implements, root-cut ash is in general use for the handles of such as require to bear great stress, as of the spade, fork, mattock, forge-hammers, &c.; willow or deal, of the lighter tools, as the hoe, rake, scythe; beech and sycamore for the common tools and instruments of carpenters; box, holly, elder, &c. for the more select tools of artisans, and for mathematical and gaugers' instruments.

6752. For utensils, under which is included household furniture, the chief British wood used by the cabinet-maker is beech for bed-frames, chairs, and sofas; next, birch and broad-leaved elm for the same purposes; oak for gothic furniture; the cherry, plum, holly, yew, box, walnut, lime, poplar, and a great variety of woods for occasional purposes; and deal enters more or less into the construction of almost every thing he makes. The musical instrument-maker uses lime, box, yew, holly, plum-tree, and poplar. The carver uses chiefly lime, and next, pine-deal; the cooper uses oak, and some chestnut for large casks and vessels, corn-measures, &c.; birch and alder for herring-barrel staves, sycamore for herring-barrel ends, and for pleasure vessels. As hinted above, a large proportion of the herring-stuffs made at home, have been in great demand (Montech); ash for dairy utensils, butter-firkins, flour-barrels, &c.; oak for well-buckets and water-pails, and, in some places, for milk-pails and other dairy utensils; beech is occasionally used for the same purpose, and for soap-firkins, and willow, oak, ash, and hazel for hoops. The brush-maker uses beech, sycamore, birch, and lime holly and box; and also poplar and lime-tree, locksmiths, the soundest oak, from the root-cut or butt-end of the trunk; the block-maker, for printing and bleaching-works, uses sycamore; the turner, beech, sycamore, box, and holly; trunk and packing-case makers, deal; the gilder, deal. For the making of square and oblong boxes, where they may be otherwise obtained, sometimes oak; basket-makers the root-shoots of the willow, and sometimes of the hazel; bee-hive and straw utensil makers use the bramble and willow; besom-makers the spray of the birch, broom, heath, last and pattener makers, alder and birch; the toy-maker, lime, and other soft woods, and also box, holly, and yew. For most of these purposes, the trees must have attained a timber size, and for some of them, they should be full-grown.

6753. For fuel, any ligneous vegetable may be used at any age, and either the body or trunk and root of the plant, or its branches and spray. Resinous trees, excepting the larch, afford most flame, and may be used the soonest after being cut; the ash next in order, then the birch, whose oily bark burns clear; oak and elm burn the slowest; and the roots of trees are generally of more slow combustion than their tops. To produce fuel in a short time, the most rapid-growing tree is the common tree-acacia (Robinia
Charcoal, as fuel, is prepared by subjecting roots, or the more ligneous parts of branches, to a smothering combustion.

6754. For affording the tannin principle, the bark of the oak is chiefly used; but that of the Huntingdon, St. John, (or St. John's) chestnut, hazel, thorn, and some other trees, is found to afford it in such quantities as renders it worth while to disbark them for that purpose. (Agr. Chem. 59. and Com. to Board of Agr.) The bark is most powerful when taken from the tree at a early age, and hence the oak is cut down before it attains a timber size, for that purpose, as in cope woods; but the bark of old timber is also used.

6755. For dying, the bark of several trees was formerly in use, as of the crab-apple, pear, ash, alder, &c. The bark of the quercitron (Quercus tinctoria) is used for dyeing yellow in North America; but in this country, the better materials, as bluing, logwood, madeira bark, &c. have superseded the use of indigenous, or home-grown vegetables. The berries of some trees, as of the elder, and berry-bearing alder; and the leaves of others, as of the walnut and sloe, have also been used as dye-stuffs.

6756. Various arts and manufactures some of the products of trees are used, as the charcoal of the dogwood principally) in that of gunpowder; the pitch of the pine, the resin of the spruce fir, and the turpentine of the larch, for a great variety of purposes. The ashes of the burnt branches of all trees, especially of the ash, afford alkali for the laundress; the spray of the beech and other trees affords, on distillation, the myrrh of the East; an excellent preservative of timber, and, when purified, a substitute for salt in preserving butcher-meat; the bark of the holly affords birdlime; and the leaves of all trees, excepting the resinous kinds, rot into excellent manure for the field, and highly prized vegetable mould for the garden.

6757. For food to man, in his present state, the timber-trees afford but little resource; but nuts of the sweet chestnut, walnut, and hazel are still esteemed, and our ancestors used the acorn, beech-mast, haw, rowan, hip, and bramble. A very agreeable drink is made from the sap of the birch-tree in Sweden, Russia, and some parts of Britain; and, in America, sugar is obtained from the sugar-maple (Acer saccharinum) in sufficient quantities to be used in domestic economy. Mast and acorns are esteemed excellent food for swine, haws for deer, and the leaves and spray of many sorts of trees are, or may be, eaten during winter bad weather. The leaves, in every country in the world, of some of the greatest luxuries of the table, is localised by plantations, in which both birds and quadrupeds find at once shelter, security from their enemies, and food.

6758. For medicine, the products of scarcely any British tree is in use; but the bark, blossoms, and berries of the elder; the fruits of the oak, and the leaf of the walnut were formerly in considerable repute, and are occasionally used.

6759. As poisons for vermin, the leaves of the walnut, elder, and ash are used by infusion for destroying insects and vermin, owing, while their bitter acrid quality; a glutinous snare for entrapping birds is obtained from the holly and mistletoe.

6760. General result. From the above outline it may be inferred, that the timber-trees in most general demand as such, are the oak, pine, and fir tribes; and next the ash, elm, beech, poplar, willow, birch, sycamore, &c. In the greatest measure can, Quercus parvula, the oak, larch, Scots pine, ash, shide, poplar, and willow, be found the most profitable trees that can be planted with a view to timber or bark produce.

Sect. II. Of the Uses of Trees collectively as Plantations.

6761. Trees collectively in a growing state may be useful by affording shelter and improving the local climate, improving bad soils, producing shade, by separation, seclusion, distinction, appropriation, concealment of disagreeable objects, heightening the effect of agreeable objects, creating beauty, and adding value prospectively.

6762. Shelter and climate. The umbrageous roof of the forest afforded shelter, and a secure retreat to our savage forefathers; and their civilised descendants still resort to the nearest tree as a place of shelter during a casual storm; to the thick forest as a place of security, when they set the laws of their country at defiance, or have committed crime. Considered agriculturally, "the advantages to be derived from subdividing extensive tracts of barren country by plantations, are evidently great, whether considered in the light of affording immediate shelter to the lands, or in that of improving the local climate. The fact that the climate may be thus improved, has, in very many instances, been sufficiently established. It is, indeed, astonishing how much better cattle thrive in fields even but moderately sheltered than they do in an open exposed country. In the breeding of cattle, a sheltered farm, or a sheltered corner in a farm, is a thing much prized; and, in instances where fields are taken by the season for the purpose of fattening them, those most sheltered never fail to bring the highest rents, provided the soil be equal with that of the neighboring fields which are not sheltered by trees. If we inquire into the cause, we shall find that it does not altogether depend on an early rise of grass, on account of the shelter afforded to the lands by the plantations; but, likewise, that cattle which have it in their power, in cold seasons, to indulge in the kindly shelter afforded them by the trees, feed better; because their bodies are not pierced by the keen winds of spring and autumn; neither is the tender grass destroyed by the frosty blasts of March and April." (Plant. Kal. p. 121.) In gardening, as we have already seen (2400.), shelter is not less important than in general economy.

6763. Climate. An Italian author (G. Gautieri) has enumerated and illustrated the advantages, in point of climate, of afforestation from extensive schemes of wood-forestry, on the following points: "are the arresting the progress of impetuous and dangerous winds; maintaining the temperature of the air; regulating the seasons; lessening intense cold; opposing the formation and increase of ice; moderating intense heats; producing abundance of rain and snow; giving origin to springs, and producing abundance of water in the rivers; discharging the electricity of the atmosphere; dispersing hail, snow, and watery clouds; preserving from inundations; lessening the width and depth of torrents; opposing a barrier to the undermining of banks, and the formation of precipices; preserving the soil on mountains, banks, country roads, &c. From these, in the first place, are produced the slighting of the formation of avalanches, or accumulations of snow." He illustrates each of these propositions by references to what has taken place in Italy and Germany, in consequence of alterations that have been made in the woody surfaces of these countries. (Dello Influsso de' Boschi, &c. Milan, 1817.) Williams, an English author (1829.), has endeavored to show that the climate of Britain is deteriorating by the increase
of plantations. These, whether in masses or even in hedge-rows, increase the evaporating surface, and consequently render the atmosphere more humid; an open country, he says, would be more dry, airy, and wholesome. This is, no doubt, correct; and, perhaps, some valleys and plains are more thickly studded with ditches, roads, and cattle paths, than a strict regard to the culture of corn, or the salubrity of the atmosphere, would justify: but the same objection at not applying to this, wherever every one allows are greatly improved by planting, both in climate, agricultural produce, and general effect.

564. Improving bad soils. "It certainly is not one of the least recommendations of planting," observes Poynter, "that it may be made to contribute essentially to the improvement of a bad soil, as is the case on sterile heaths and commons, where three means, the consequences of the planting, act together in promoting such improvement. The first is, the shade of the trees, which, by decomposing the vegetable matter, and rendering it more fertile, that is, more capable of being easily penetrated by the roots. The second is, that by the decomposition of the annual fall of leaves, an addition is made to the vegetable soil, and that of the very best description. The third circumstance is, that as the roots collect a great deal of their support from a depth much lower than field vegetables are used to reach, they hence convert the useless into useful. In short, instances are not wanting, where land previously producing little besides heath, has, after producing a crop of trees, more especially firs, proved without further means very tolerable pasture." (Profitable Planter, p. 25.) A healthly tract is referred to between Cupar and Perth, containing 3000 acres, which, after being twenty years under a crop of scotch firs, was profitably subject to aration.

565. The shade of trees is highly grateful to man, whether reposing under a single tree, or in a state of recreation under the shadow of a row, or in an avenue, grove, or woodland path. "Shelter," Sang observes, "is not more useful in cold seasons, than the shade of trees is gratifying to cattle in hot ones. In an exposed open field, under a burning sun, the torture which cattle often endure is truly distressing." (Plant. Kal. 152.) In garden culture, shade is of great value; but walls are occasionally preferred to trees for this purpose; and next to walls, hedges or trees cut in the hedge manner.

566. The separation produced by ligneous vegetables, in the form of hedges, is of long use in gardening, and of great and acknowledged importance in agriculture. In the latter art it may be considered as a criterion of improved culture; for when land lies intermixed, and is cultivated in what is called the common-field manner, the want of sufficient individual interest precludes all extraordinary exertion, and the country is cultivated has the same appearance now, that it had many centuries ago. Even on entire properties lying open, the want of the power of separating and classing cattle, and regulating their mode of grazing, and protecting particular fields for particular purposes, &c. is found so great a disadvantage as to be quite incompatible with the practice of improved farming.

567. The seclusion afforded by trees, either as hedges, rows, strips, or groups to dwellings or gardens of limited surrounding territory may be desired from taste, or rendered necessary by personal infirmity, political, local, or pecuniary circumstances. Trees, by their elevation and foliage, shut out external objects, obstruct the gaze of the over-curious, and do not invite the visits of any one; while they leave the occupant in the centre of a little world of his own, in which he may enjoy himself in his own way.

568. The distinction any sort of trees afford to a dwelling in a naked solitary country, or exotic species in an already wooded, is often desirable, as conveying cheerful and social ideas to the passing stranger, and procuring for the owner that applause for improvement which he feels to be his due. In extensive demesnes the outlines or prominent parts of them, may be indicated by particular sorts of trees; so as, from the house, or from a prospect-tower, in a central part of the estate, to render the contour of the whole distinguishable. Where common, or any one kind of trees abound, uncommon or exotic kinds may be made use of; or a common tree, pruned in a particular way, will have an adequate effect.

569. To appropriate, harmonise, or render apparently a part of a near estate, distant woody territory which does not belong to it, may be considered as a subsilsh principle under the disguise of a social one; but it is, at all events, harmless in a moral point of view, and is valuable as a device in improving the beauty of real landscape. Whatever may be the kinds of trees, or the forms in which they are planted in the distant or adjoining property, which we may wish to appropriate (fig. 625. a, b); the principle is, to plant the same sorts of trees in corresponding forms (b, a), in the property which we can call our own.

570. The concealment of disagreeable objects by trees is too obvious, useful, and universal an improvement to be regarded as an object of the slightest importance. To one of them, it is even to small demesnes in a populous country, or near large towns. The desire of shutting out the houses of others, and especially of our poorer neighbors, does not so much arise from dislike either to the objects or the inhabitants, as from love of verdant scenery, and from a wish to have a country-seat as much like the country as possible. The desire of shutting out manufactories, steam-engines, coal-works, water-houses, &c. is still greater, because these objects excite ideas by no means in harmony with rural quiet; but no one ever thinks of shutting out a distant farm-house, solitary cottage, church, water-mill, bridge, monument; in short, there are many in these respects disgusting and agreeable objects, which are either characteristic of the country, or very generally occur there.

571. Trees heighten the effect of agreeable objects by associating or grouping with them; and thereby forming a more perfect whole. Every whole consists of a number of parts, and the more varied the parts, provided they are allied among themselves, and not confused or redundant, the greater must be the effect of the whole. Trees contribute to the beauty of objects already beautiful; by lending new forms, new colors, varied light and shade; by their own motion, by inviting birds, and even by their smell. All these qualities are interesting to the moral and picturesque observer, and of great
importance to the improver, whether he displays water, or erects buildings, or harmonises rocks and mountains. A country-house without trees is felt by every one to be but a part of a whole.

6772. Trees may direct the eye to objects that would otherwise escape notice, or whose beauties would be lost in a general view. By employing them in the foreground of a scene to shut out uninteresting distance or mere sky, the eye may be led to repose on some agreeable near, or interesting distant object, which it had before wandered over unnoticed. By this sort of indication, accompanied by a seat, the dome of St. Paul's at London, of St. Peter's at Rome, and the cupola of the Ivan Willks of Moscow, are seen from the grounds of residences at twenty or thirty miles' distance from these capitals; and in this way the worthy and amiable Shenstone, pointed out the Wrekin, and church-spire of Halesowen, from the rustic path of the Leasowes.

6773. Trees render indifferent objects interesting when judiciously grouped with them, so as to seem to conceal, by accident, that which we should desire or imagine to be there. Thus, a fragment of a wall, or of a tower, emerging from a thicket, may, by imagination be considered as an index to the main body of the ruined mansion or castle concealed by the wood. A broken gothic arch emerging from a thick wood may seem the commencement of a cloister or the aisles of a ruined abbey. A large stone lying on a naked surface is an object of little interest in a picturesque point of view, but surrounded by a few trees and bushes, it may be taken for part of a stratum of rock. A few yards of brick wall, standing naked and bare in a field would be considered as a deformity; partially cover it with ivy, which may first ascend and then mantle over its top, and add a holly or thorn, a briar, and an oak or ash, and a beautiful group is produced. In scenery, where great deformities or featureless extent is mixed with beauty or grandeur, trees will conceal the latter, and display the former to advantage. Ranges of naked mountains often present this kind of mixture of feature, dulness and want of grouping (fig. 623.), which no improvement but planting could ameliorate and render tolerable. Gilpin, in his Tours to the Lakes and Highlands, &c. has some excellent observations on this subject; and there is a figure in the Pent-hill, showing Grampian ranges of hills where improvements of this sort have been executed with the happiest effect. (fig. 627.)

6774. Beauty may even be created by trees independently of all other objects. A dull flat surface will be rendered more interesting by scattering a few trees over it, of any sort, and in almost any manner: but it may be grouped or massed by one, a few, or by many sorts; or laid out in avenues, stars, platoons, and other modern or ancient forms of planting, so as to become a scene of positive beauty. Every species of trees has its particular form, bulk, mode of growth, flowering, &c. which constitute its character; this character varies with the tree, and its situation, relative to other trees, or to soil, climate, &c. Now, as every tree may be grouped, or combined with those of its own species, or with any or all of the others, in an endless variety of ways, the beauty that may thus be created by trees alone, can only be limited by the extent of surface on which they are to be grown.

6775. The value of landed property containing plantations is enhanced prospectively by the various properties of trees. "It is very generally known," Sang observes, "that such estates as have a quantity of well arranged, healthy timber upon them, when brought to sale, bring an extra price, according to the quality and value of the wood, not only at the time of sale, but, counting forward on its value, to the period of its perfection. Thus, supposing the half-grown timber on an estate to be valued at ten thousand pounds at the time of the sale, instances are to be found where thirty thousand pounds have been given, over and above the valuation of the lands. The purchasers of such estates wisely foresee the increase of value which will arise from healthy timber growing where it may not only be cherished till of full maturity, but where, probably, it can then be turned to the best advantage by reason of its local situation. But, besides the real value of grown timber, there is most generally an ideal value attached to it, namely, that of its ornamental appearance." (Plant. Kol. 12.) A landed proprietor, who is a parent, looks on a thriving plantation as capital laid out at compound interest, and on the most undoubted security, for the benefit of his offspring; and he values it in this respect the more, because no man can determine the ratio in which, from the progress of the trees, and the future prosperity of the country, it may increase in value. It does not happen to many to plant trees and cut them down at a mature age; but this only renders planting a more interesting performance to the man who is in secure enjoyment of an estate; for in his full-grown trees he finds a link which connects him with his ancestors, and in his young plantations another which carries him down with his posterity to the next age. In this way he may imagine himself a being "having neither beginning of days nor end of life."
Sect. III. Of the Profits of Planting.

6776. From the seemingly distant advantages of planting has arisen the practice, by authors, of presenting statements of the profits, pleasures, and honors attending it, with a view to excite the selfish or patriotic feelings of their readers. "The profits of planting," says Marshall, "are great, when properly executed, and this idea adds solidity to the enjoyment. Pleasure alone may satiate; but profit and pleasure united seldom fail of producing a lasting gratification." Every one who has the least taste for country matters, must be alive to the agreeable and satisfactory feelings with which plantations are formed; and certainly there is something disinterested and respectable in incurring a present expense for what in most cases is to benefit a future generation; but as to the extraordinary profits, either of a near or far distant period, they are by no means to be depended on. With respect to the absolute profit to be derived from trees or plantations, considered independently, it is easy, by a calculation founded on a seemingly very moderate data, to make the clear gain attending the raising of any crop appear considerable; and, accordingly almost every speculative cultivator, whether of corn or trees, calculates on making a fortune in a very few years, as soon as he can get possession of a farm or a tract of waste. The truth is, however, that though accidental circumstances may render it more profitable to cultivate one kind of crop, either of trees or corn, at one time and place rather than another; yet, on the whole, the profits of capital employed in any way in agriculture or planting must, on the general average, be nearly the same. The certain lapse of time which must ever intervene between the planting of trees and their attaining a disposable size, must alone render any calculation made at the time of planting, extremely problematical. In planting, as in every other branch of culture, extraordinary profit is attended by extraordinary production, which soon sinks the market value of the article; add also, that in a commercial, free and highly taxed country, whenever any article attains a very high price, substitutes are found at home, or imported from abroad; so that no particular crop should be considered as exclusively the best to cultivate, and no extraordinary profits ever calculated on from any crop. Plantations should be made with a joint view to all or part of the advantages which we have shown to be attendant on them; but no more ultimate profit calculated on, from the disposal of the trees, than what is expected from capital laid out on any other territorial improvement; indeed, the safest principle on which to act, is to consider capital employed in planting, as on a par with that laid out in the purchase of landed property.

6777. With respect to the value of trees as plantations, or in masses, that is entirely relative; and must be sought for in the additional value conferred on the adjoining lands by the improvement of their climate, or their beauty. This sort of value cannot easily be subjected to any general rules of estimation; but unquestionably capital employed in planting and cultivating trees for such purposes, especially for the former, or when they are both united, may be considered as likely in the end to yield a greater interest than that employed in the ordinary routine of tree or corn culture. In bleak exposed situations, the advantages which have arisen from screen plantations have in some cases been so great as to be estimated at a third of the value of the land, and in every case where shelter is wanted they must be considerable. These, however, should be looked on by the prudent man rather in the light of extraordinary cases, attended by unforeseen risks, and though depending chiefly on skill, yet in some degree also on chance.

Chap. II.

Of the different kinds of Trees and Plantations.

6778. Having considered the different objects for which trees and plantations are cultivated, our next step shall be to arrange trees and plantations, according to their qualities, for fulfilling these objects.

Sect. I. Of the Classification of Trees relatively to their use and effect in Landscape.

6779. Timber is the grand object for which trees are cultivated, and it is either straight or crooked in form, large or small in dimension, hard, soft, or resinous in quality, brittle or flexible in texture, smooth or rough grained, and plain-colored or variegated in appearance.

6780. Straight timber is chiefly produced by the pine and fir tribes, and such other trees whose lateral branches do not generally acquire a timber size, as the Lombardy poplar, hornbeam, deciduous cypress.

6781. Crooked timber may be produced by any branching tree; but chiefly by the oak, sweet chestnut, broad-leaved elm, walnut, &c.

6782. Timber of large dimension, in regard to length, is produced by the spruce fir, larch, Lombardy poplar, ash, narrow-leaved elm; in regard to diameter by the oak, sweet chestnut, and elm; magnitude in both dimensions is united in the narrow-leaved elm, beech, oak, and larch fir.

6783. Timber of small dimensions is produced by the yew, holly, thorn, ash, maple, laburnum, &c.

6784. Timbers, hard in quality, or, what are called the hard woods, are the oak, chestnut, sycamore, ash, beech, plane, walnut, box, holly, yew, &c. Softer timbers, or the soft woods, are the poplar, willow, lime,
horse-chestnut. Resinous timbers are the pine and fir tribes. Brittle timber is exemplified in acacia, hornbeam, and spindle-tree; flexible, in the ash, broad-leaved elm, and chestnut; smooth-grained, in the lime, poplar, willow, hornbeam; coarse-grained, in the oak, and chestnut; plain-colored, in the willow, lime, hazel, alder, and elm; smoother, in the lime, plum, and alder.

6785. Bark, which contains the tannin principle, is an important product of trees. That which affords it in greatest quantity is the oak; and next, as far as chemists have yet ascertained, the Leicester willow (Salix alba, var.), Spanish chestnut, ash, sloe, Lombardy poplar, hazel, elm, common willow, sycamore, beech, horse-chestnut, birch, and larch. (659. & Agr. Chem. 89.)

6786. Charcoal, which is made from either branches, trunk, or roots, has been afforded by different trees at the following rates per cent.; laburnum, 24.5; chestnut, 33.5; oak, 26.6; walnut, 30.6; holly, beech, maple, 19.9; elm, 19.5; Norway pine, 19.5; sallow, 18.4; ash, 17.9; birch, 17.4; Scotch pine, 16.4. (Agr. Chem. 105.) Proust found the greatest proportion of charcoal to be afforded by the ash. (658.)

6787. Alder which is afforded in the poorest results of 12; elm, 20; beech, 12; and poplar, 7 parts in ten thousand. (Agr. Chem. 113.) The result of Saussure's experiments, on procuring ashes from trees, have been already related. (703.)

6788. For fuel and fencing. The tendency of trees to produce lateral branches, and renew them when lopped off, is an important quality, and exists in an eminent degree in the ash, elm, oak, willow, poplar, lime, &c.; but not at all in the pine and fir tribes, and but slightly in the plane, walnut, and some others. Those which grow most rapidly are also to be desired as fuel-trees, as the acacia, poplar, willow, in most soils; and the larch fir, Scotch pine, and birch, on such as are dry. The allantus glandulosus may also be mentioned as a bulky and rapid-growing tree. On the chalky hills at Mereville (before the revolution one of the most extensive parks and magnificent seats in France), this tree thrives, and attains a considerable size, where few others will grow.

6789. For hoops, basket-voitouns, besom-sprigs, implement-handies, poles, &c. the renewal of trees or shrubs which have been cut down, or technically, their tendency to stale or shoot out from the collar, is an important consideration. This quality does not belong to the pine and fir tribes; and only slightly to the beech, linden, hornbeam, elm, &c.; nor to any of those mentioned above, as renewing their branches, and indeed to most trees not resinous. For the same objects, the tendency of trees to send up suckers or root-shoots deserves also the attention of the planter. This never takes place with the resinous trees, and seldom with the oak, beech, chestnut, ash, lime, &c.; but it is general with the elm, poplar, acacia, prunus, pyrus, mespilus, lime, and several willows.

6790. For shelter, rapid-growing and evergreen trees are desirable, as the Scotch pine; and such as are at the same time clothed with branches from the ground upwards, as the spruce fir; the best of all trees for shelter, unless the situation is very elevated. Among the deciduous trees, the fast-growing branchy sorts are most desirable, as the larch, birch, poplar, willow; in very elevated situations, the birch, mountain ash, and Scotch fir; exposed to the sea-breeze, the elder and sycamore. To maintain a branchy leafy screen from the ground upwards, intermix trees and shrubs which stole; or such as grow under the shade and drip of others, as the holly, hazel, dogwood, box, yew, &c. To produce shelter, and yet admit of the growth of grass below the trees, prune any sort to single stems, and use chiefly deciduous sorts.

6791. For shade, close plantations are seldom desirable, a free circulation of air being necessary to coolness; therefore use trees with lofty stems and large heads, and prune them to single stems a certain height, as the oak, elm, chestnut, beech, for thick shade; the plane, acacia, poplar, for lighter shade; the birch, balm of Gilead fir, and lime, for odoriferous shade; and avoid the walnut, elder, and laburnum, the atmosphere of which is reeked with deaths and diseases. For improving bad soils, and for all the purposes of planting, the soil and situation, affected by or natural to trees, is an important study for the planter. Some are aquatic, or delight in moist situations near water, as most of the willow, elm, poplar tribes, the elder and elder, others are mountain trees, as the Scotch pine, larch fir, mountain ash, sorb; some delight in valleys or plains, as the narrow-leaved elm, horse-chestnut, plane, lime, oak; others, in craggy steeps and dells, as the ash, silver and spruce firs, most of the pines, and many more; some on chalky soils, as the beech; others on clays, as the oak; on sand, as the bay, pine; and a few on slopes, as the most opposite situations and soils, as the elder, which is found on mountain tops and on the sea-shore; the birch on the highest mountains, on dry rocks, and on marrows. For the poorest soils, whether high or low, choose the birch, larch, and Scotch pine; and for the richest, the ash, elm, oak, chestnuts, limes, poplars, and willows.

6792. For the separation of, or defence from the inferior animals, the plantations called hedges, or close rows of shrubs, are adopted; when these are to be low, such shrubs as send out numerous branches from the root upwards, and are of great durability, are most desirable; as the holly among evergreens, and elder, hornbeam, and hawthorn, among deciduous sorts. For moist situations, the elder, elder, birch, and willow, are to be preferred; and for dry upland sites, the juniper, whin, birch, and elder; avoid poisonous trees, as the yew. For tall or tree hedges, such trees as the elm, beech, hornbeam, lime, birch, and spruce fir, are desirable; but the holly excels all other plants for a hedge, whether low or tall, and is liable to no other objection than its slow growth, which occasions a considerable expense in protecting it till it is able to serve for defence.

6793. For seclusion and concealment, branchy leafy trees, a number of which have been mentioned (6750.), are obviously desirable; and, for convenience, either of these, different from what are already there, or others the same, are not only prepared and made to assume extraordinary forms.

6794. For the various purposes of ornament, beauty, or effect, in landscape, the hardy trees may be arranged as to magnitude, form, mode of growth, duration, and expression.

6796. Magnitude. Trees of great height are, the English elm, ash, larch, Polish and Carolina poplars, &c.; but the laburnum, mountain ash, and evergreen oak, are very low trees. A medium in height may be found in the maple, pine, and birch. Some trees exceed in breadth, as the oak, Spanish chestnut, and Scotch elm; others of different heights are very slender, as the Lombardy poplar, cypress, and bird-cherry.

6797. Form. The oak and Spanish chestnut afford the most irregular and picturesque
shapes, with round heads; the English elm and ash have long narrow forms, and round heads; the beech and horse-chestnut, compact ovate forms, with obtuse heads; the spruce and pine tribes, in general, have conical shapes, and pointed spiry tops; the Lombardy poplar, cypress, and most willows, have long narrow shapes, and oblong tops.

6798. Color. The Scotch pine, yew, and horse-chestnut, are dark-green; the larch and elm, a yellow-green; the able, Huntingdon willow, a silvery-green, &c.

6799. Mode and time of growth. The nature of some trees is to lose their lower branches as they increase in height, as the fir tribe; and others have a tendency to retain them, as the yew elm. In some the branches descend, and often recline on the ground, as the lime-tree and platanus. Some are very compact in their foliage, as the horse-chestnut; others very open, as the ash and acacia. Some have drooping spray, as the weeping-willow; that of others tend upwards, as in the Lombardy poplar; horizontally, as in the oak; and obliquely, as in the Scotch pine. Some grow with rapidity, as the Carolina and Athenian poplars; others very slowly, as the oak and the stone pine.

6800. Duration. The most durable of trees is the oak; the least so, some of the poplar and fir tribes. A medium is to be found in the elm and lime.

6801. Expression. Some trees convey ideas of utility in the arts, and mark the attention and industry of man, as having planted them for this purpose, as the oak, ash, elm, &c. Others are known, or supposed to be of little use, and convey ideas of neglect or of wildness, as the hornbeam, sorb, trembling poplar, &c. Some indicate general improvement and artificial plantations, as the larch, and spruce fir; others, garden-scenery or plantations near a house, as the cedar, stone pine, and platanus. Some indicate rich deep soil, as the oak; and rich thin soil, as the elm; others, chalk or gravel, as the beech; rocky ground, as the ash; marshy ground, as the alder; the proximity of water, as the willow. There are also natural expressions belonging to trees, partly from general, and partly from accidental association; as strength and stability to the oak, ease and elegance to the birch, sweetness to the lime, gloom to the cypress and yew, melancholy to the weeping-willow, &c.

6802. The common hardy shrubs may be similarly arranged; but it will be sufficient to class them according to magnitude, mode of growth, evergreen, deciduous, native, naturalised, and exotic.

6803. Magnitude. Some shrubs are high, approaching to the character of trees, as the mespilus and common holly; others very low, as the butcher's broom and dwarf-birch.

6804. Mode of growth. Some are creepers, as the ivy; climbers, as the virgin's bow; trailers, as the bramble; compact forms, as that of the arbor vitae; open airy branches, as in the tamarisk; and singular branches, as those of the staghorn-sumach. Some, as shrubs, soon acquire picturesque shapes, as the thorn, holly, and elder. Some are evergreens, as the holly, laurel, yew, laurustinus, arbutus, &c.

6805. Deciduous, as the guelder-rose, lilac, syringa, &c.

6806. Native, as the holly, privet, hazel, thorn, briar, &c.

6807. Naturalised, as the rose, syringa, lilac, laburnum, &c.

6808. Exotic, or foreign, as the rhododendron, azalea, &c.

6809. These arrangements as to the effect of trees and shrubs in landscape, as far as form, magnitude, mode of growth, and expression are concerned, refer to plants growing detached from other trees, and as nearly full-grown. It is less intended to comprehend every characteristic distinction than to suggest to the artist the principal light in which he ought to view trees and shrubs. Nor could he with confidence attempt planting, with even such a knowledge as could be obtained from the above arrangement, completed by inserting all the names under their proper heads; for unless he has seen the majority of the full-grown trees himself, both singly and connected in groups and masses, and is acquainted with the comparative rapidity of their growth in different climates and soils, he cannot well foresee the result of his labors, or look forward "with the prophetic eye of taste" to certain beauty. Of this there are numerous proofs, arising from the unjust preference given to exotics of unknown shapes and duration, in situations where the general form and situation of the trees, or even of one or two trees, is of the utmost consequence to the effect of a whole. How frequently on a lawn, or in a plantation near a house, do we see acacias, cut-leaved elders, variegated sycamores, &c. where the oak, cedar, beech, lime, or Spanish chestnut would have produced a much more impressive general effect!

Sect. II. Of the Classification of Plantations, or Assemblages of Trees.

6810. Assemblages of trees, whether natural or artificial, differ in extent, outline, disposition of the trees, and kind of tree.

6811. In regard to extent, the least is a group (fig. 628. a and d), which must consist at least of two plants; larger, it is called a thicket (b); round and compact, it is called a clump (a); still larger, a mass; and all above a mass is denominated a wood or forest, and characterised by comparative degrees of largeness. The term wood may be applied to a large assemblage of trees, either natural or artificial; forest, exclusively to the most extensive or natural assemblages.

6812. With respect to the outline, or ground-plan of a plantation, the simplest disposition is that of a row or line, which may be either straight or crooked, as in hedges, or lines of trees; next that of any determinate shape, as round, exemplified in the clump; square, in the platoon; oblong, in either clump or platoon, and in stripes, screens, or belts; irregular or indeterminate, in thickets, masses, and all larger plantations.

6813. With respect to the disposition of the trees within the plantation, they may be placed regularly in rows, squares, parallelograms, or quincunx; irregularly in the manner of groups; without under-growths, as in groves (fig. 629. a, b); with under-growths, as in woods (c); all under-growths, as in copses.
6814. With respect to the character of tree-plantations, they may be as various as there are species; but for general effect and designation, woody plants are classed as large or small, trees or undergrowths, deciduous or evergreen, round-headed or spiry-topped; and plantations of every form and disposition may be planted with these, either separately or mixed. Thus we have groups of shrubs, groups of high and low growths, and of trees; plantations of round-headed and spiry-topped trees mixed; of trees and undergrowths; or of low growths only, as in copse-woods and osier-plantations.

Chap. III.

Of the Formation of Plantations, in which Utility is the principal Object.

6815. The formation of useful plantations embraces the situation, soil, form, species of tree, fencing, and other considerations.

6816. A sheltered situation and deep rich soil would be the most proper if the object of the planter was to obtain the greatest bulk of timber in the shortest time; but this would not be profitable planting, for such a soil would, in all probability, have made greater returns under common farming. The profits of planting do not depend on the absolute quantity of timber produced, but on that quantity relatively to the value of the soil for agricultural purposes. Such situations and soils as can be profitably subjected to aration or permanent pasture, will rarely be found to yield an equal profit, if planted with trees. Suppose a piece of ground to let at 20s. per acre for pasture or arable, to be planted at an expense of only 10s. per acre; then, in order to return the rent, and 5l. per cent. for the money expended, it ought to yield 30s. a year; but as the returns are not yearly, but say at the end of every fifteen years, when the whole may be cut down as copse, then the amount of 30s. per annum, at 5l. per cent. compound interest, being 332. 8s. every fall of copse made at the interval of fifteen years, ought to produce that sum per acre clear of all expenses. Hence, with a view to profit from the fall of timber or copse-wood, no situation capable of much agricultural improvement should be planted, unless a certain part with a view to sheltering the rest; or for the purposes of separation and fencing.
6817. Whatever may be the nature of the soil, the sub-soil ought to be rendered dry if the plants are intended to thrive. Large open drains may be used, where the ground is not to undergo much preparation; but where it is to be followed or trench'd, under-drains become requisite. It is true, these will in time be choked up by the roots of the trees; but by that period, as no more culture will be requisite, they may be opened, and left open. Many situations, as steep sides of hills and rocky irregular surfaces, do not admit of preparing the soil by comminution previously to planting; but wherever that can be done, either by trenching, digging, or a year's subjection to the plough, it will be found amply to repay the trouble. This is more especially requisite for strips for shelter or hedge-rows, as the quick growth of the plants in these cases is a matter of the utmost consequence. The general mode of planting hedges by the side of an open drain, renders preparation for them, in many cases, less necessary: but for strips, wherever it is practicable, and there is at the same time no danger of the soil being washed away by rains or thaws, as in some chalky hilly districts; or blown about by the wind, as in some parts of Norfolk, and other sandy tracts, preparation by a year's fallow, or by trenching two spits deep, cannot be admitted without real loss, by retarding the attainment of the object desired. There are instances stated of promising oak-plantations from oaks dibbled into soil altogether unimproved; and of plantations of Scotch pine, raised by merely sowing the seeds on a heath or common, and excluding cattle (Gen. Rep. of Scotl. ii. 682); but these are rare cases, and the time required, and the instances of failure, are not mentioned. The practice is obviously too rude to be recommended as one of art. The best situations for planting, without any other culture but inserting the seeds or plants, are surfaces partially covered with low woody growths, as broom, furze, &c. "The ground which is covered, or rather half covered, with juniper and heath," says Buffon, "is already a wood half made."

6818. Oak-plantations are an exception to these remarks, as to the value of the situation and soil; they require a deep, strong, moist soil, but one not springy, or continually saturated with water; and it will be in vain to plant them without trenching it two or more feet deep.

6819. The form of plantation for profit or shelter must be determined jointly by the situation and the objects in view. In rocky abrupt sites (fig. 682.), the plantation will consist of a number of masses (a, b, c), of forms determined by the rocks and precipices, among which some of the most valuable pasture may be left as glades (d, e), for use, effect, and for the sake of game. Strips and hedges for sheltering or separating arable lands, should be formed as much as possible in straight and parallel lines, in order not to increase the expense of tillage by short and irregular turnings. Straight parallel strips, on irregular surfaces, have a more varied appearance at a distance, than strips ever so much varied on a flat surface; for, in the former case, the outline against the sky is varied as much as that on the earth. In extensive hilly pastures, in which it is often desirable to produce shelter, and at the same time to plant only the most rocky and unproductive spots, the forms may be of the most irregular description; and by planting chiefly on the eminences and slopes (fig. 683.), shelter will be most effectually produced, the pasture improved, the least valuable ground rendered productive in copse or timber, and the greatest richness and picturesque beauty conferred on the landscape. There are some fine examples of this on the hilly districts of Fifeshire; there, on many estates where nothing was sought for but profit and shelter, the greatest beauty has been produced; and the picturesque tourist now passes through glades and valleys, pastured by well-fed cattle and sheep, enlivened by rocks, thickets, hanging woods, and occasional rills and lakes. Fifty years ago, scarcely a tree was to be seen, and only the most inferior descriptions of live stock.

6820. The enclosing of plantations is too essential a part of their formation to require enlarging on. In all those of small extent, as hedges and strips, it is the principal part of the expense; but to plant in these forms, or any other, without enclosing, would be merely a waste of labor and property. The sole object of fencing being to exclude the domestic quadrupeds, it is obvious, that whatever, in the given situation, is calculated to effect this at the least expense, the first cost and future repairs or management being taken into consideration, must be the best. Where stones abound on the
only to be guarded on the exterior side, and of the various ways in which this is done, the following may be reckoned among the best and most generally applicable. By an open drain and paling, or line of posts and rails (a), the plants inserted in a facing of stone, or in a facing of sub-soil from the bottom of the drain, backed by the earth of the drain (b); an excellent mode, as the plants generally thrive, and almost never require cleaning from weeds; an open drain and paling, and the hedge on the top of the elevation (c); no open drains, but the soil being a loam, the surface-turfes formed into a narrow ridge, to serve as a paling, a temporary hedge of furze sown on its summit, and the permanent hedge of thorn or holly within (d); and an open drain, but on the inside, the exterior being protected by a steep bank sown with furze (e). The first of these modes is the most general, the second the best, and the fourth the cheapest, where timber is not abundant. Separation fences are commonly formed in the first, second, or third manner, but with a paling on both sides.

6821. Shelter. Many situations are so exposed that it is extremely difficult to rear trees without some mode of procuring shelter for them during their early growth. This is obtained either by walls, the extent of whose influence is only limited; by thick planting, or by planting the more hardy and rapid-growing species, as the nurse by later growth, may render the Instead of the latter, a more directly valuable. The proportion of nurses to principals is increased according to the bleakness of the site. Pontey says, "both authors and planters are in the habit of erring egregiously, in regard to the proportion of principals and nurses; as they generally use as many, or more of the former than the latter." Though it is very easy to show, that they ought to use three times as many of the latter as the former. For instance, when trees are planted at four feet apart, each occupies a surface of sixteen feet; of course four of them will occupy sixty-four, or a square of eight feet; and therefore, if we plant three nurses to one principal in the latter mode, and the latter magnitude, we shall stand only eight feet apart. Nurse-plants should, in every possible case, be such as are most valuable at an early period of growth. The larch and spruce fir should be used liberally, in every case where they will grow freely; still it is not intended that they should exclude all others, more particularly the birch, which has most of the properties of fences and quick growth, on any tolerable soil or situation. It is not, however, like the others, a wood of general application. (Profttable Planter, p. 113.) Sang also adopts the proportion of three nurses to one principal, and employs chiefly the resinos tribe, and in the latter mode the timber has attained to a foot in diameter, under which size hard timber is seldom of much value. His principals are planted at from six to ten feet apart, according to the soil and situation. (Plant. Kal. p. 165.)

6822. In procuring shelter much depends on the mode of commencing and continuing plantations on bleak sites. Sang, who has had extensive experience in this subject, observes, that "every plain, and most fields and situations for planting, in this country, have what may be called a windward side, which is more exposed to the destructive blast than any other. It is of very great importance to be apprised of this circumstance, and to be able to fix upon the most exposed side of the proposed forest plantation. Fix, then, upon the windward side of the plain which is to be converted into a forest; mark off a horizontal stripe, or belt, at least a hundred yards in breadth. Let this portion of ground be planted thick, say at the distance of thirty fitches, or at the most three feet, with a mixture of larch, sycamore, and elder, in equal quantities, or nearly so, if the soil be adapted for rearing these; but if it be better adapted for Scots pines, then let it be planted with them at the distances prescribed for the above mixture. We have no other kind that will better, or rise more quickly in bleak situations, than those just mentioned. When the trees in this belt, or zone, have risen to the height of two feet, such hard-wood trees as are the more upright, are to be introduced, at a distance of eight, or ten feet from the principal, and ten, or twelve, feet from each other, as circumstances may admit. At this period, or perhaps a year or two afterwards, according to the bleak or exposed situation of the ground, let another parallel belt, or zone, of nearly equal breadth, be added to the one already far enough up, and so on, till the whole ground is covered. It is not determined, in same degree of the subsequent belts or zones, the breadth of the exposure of the grounds, by the shelter afforded by the zone previously planted, and by such like circumstances. (Plant. Kal. p. 29.)

6823. In situations exposed to the sea-breeze a similar plan may be successfully followed, and aided in effect, by beginning with a wall; the first belt having reached the height of the wall, plant a second, a third, and fourth, and so on till you cover the whole tract to be wooded. In this way the plantations on the east coast of Mid-Lothian, round Gossford House, were reared; and in Sang's manner, the mountains of Blair and Dunkeld were clothed; and examples, we are informed, might be drawn even from the Orkney and Shetland islands.

6824. The species of tree to be planted must ever depend chiefly on the situation and soil, but partly also on the quality of the soil, and the climate. As a general principle it may be observed, that the tree which will thrive the best, will turn out the most profitable: for, though its timber may not be of the highest-priced kind, yet there will be quantity as compensation for inferior quality. In rocky irregular surfaces there is generally great variety of situation and depth of soil; and here a corresponding variety of trees may be introduced, and the more valuable sorts, as the oak, ash, elm, poplar, &c. will nowhere thrive better than at the foot of precipices, and in narrow dells and other sinuosities, where there is at once shelter and a good depth of dry soil. The thriving of trees and plants of every kind, indeed, depends much more on the quantity of available
soils, and its state in respect to water and climate, than on its constituent principles; moderately sheltered and on a dry sub-soil, it signifies little whether the surface strata be a clayey, sandy, or calcareous loam; all the principal trees will thrive nearly equally well in either so circumstanced; but no tree will become more vigorous, or, when once matured with its timber, those kinds which grow with lofty stems, which draw their nourishment from the sub-soil, and do least injury by their shade, are to be preferred. These, according to Blakie, are oaks, narrow-leaved elm, and black Italian poplar; beech, ash, and fir, he says, are ruinous to fences, and otherwise injurious to hedges. (On Hedges and Hedge-row Timbery, p. 10.)

6825. The common practice in planting is to mix different species of trees together, which is unavoidable where nurse or shelter plants are introduced; where these are not wanted, the opinions of planters are divided on the subject. Mixing different sorts is most generally approved of. Marshall advises mixing the ash with the oak, because the latter draws its nourishment chiefly from the sub-soil, and the former from the surface. Nicol is an advocate for indiscriminate mixture (Practical Planter, p. 77.) and Pontey says, "both reason and experience will fully warrant the conclusion, that the greatest possible quantity of timber is to be obtained by planting mixtures." (Troy. Planter, p. 119.)

6826. Sang is "clearly of opinion, that the best method is to plant each sort in distinct masses or groups, provided the soil is properly kept in view. There has hitherto been too much random work carried on with respect to the mixture of different kinds. A longer practice, and more experience, will discover better methods in any science. That of planting is now widely extended; and improvements in all its branches are introduced. We, therefore, having a better knowledge of the possibilities, perhaps, than our forefathers had, can, with greater certainty, assign to each tree its proper station. We are better informed of the soil where there the one and the other again the beech; and the same with respect to the others. If, however, there happen to be a piece of such a quality, that it may be said to be equally adapted for the oak, the walnut, or the Spanish chestnut to the proper; in such a situation, that plant each in its place, it will extract its own proper nourishment, and will have an enlarged range of pasturage for its roots, and consequently may make better timber-trees. Although by indiscriminately mixing different kinds of hard-wood plants in a plantation, there is hardly a doubt that the ground will be fully cropped with one kind; yet, in very often cases, in casks, and plots, sprout the most valuable sorts, as the oak perhaps, that there is hardly one oak in the ground for a hundred that ought to have been planted. We have known this imperfection in several instances severely felt. It not unfrequently happens, too, that even what oaks, or other hard-wood trees, are to be met with, are overtopped by valuable kinds, or perhaps much more valuable place. Such evils may be prevented by planting with attention to the soil, and in distinct masses. In these masses are ensured a full crop, by being properly nursed, for a time, with kinds more hardy, or which afford more shelter than the valuable plants. There is no rule by which we can proceed. Indeed, the more various they be made in size, the better will they, when grown up, please the eye of a person of taste. They may be extended from one acre to fifty or a hundred acres, according to the circumstances of soil and situation: their shapes will accordingly be as various as their dimensions. In the same manner ought all the resounding kinds to be planted, which are intended for timber-trees; nor should these be intermixed with any other sort, but be in distinct masses by themselves. The massing of harch, the pine, and the fir of all sorts, is the least laborious and surest means of producing good, straight, and clean timber. It is by planting, or rather by sowing them in masses, by plantations become, by a timely pruning and gradual thinning, that we can, with certainty, attain to this object." (Plant. Kat. 162. 166.)

6827. Our opinion is in perfect consonance with that of Sang, and for the same reasons; and we may add is an such hard-one, that in the mass is no rule by which to or on the sides of even will grow these, occupying almost exclusively one soil and situation, while in forests less vigorous on inferior and on watery soils, mixtures of sorts are more prevalent. This may be observed in comparing New Forest with the natural woods round Lochlomon, and it is very strikingly exemplified in the great forests of Poland and Lithuania.

6828. Whether extensive plantations should be sown or planted, is a question about which planters are at variance. Miller says, transplanted oaks will never arrive at the size of those raised where they are to remain from the acorn. (Dict. Quercus.) Marshall prefers sowing when the ground can be cultivated with the plough. (Plant. and Rur. Orn. i. 123.) Evelyn, Emmicher, and Speedley are of the same opinion; Pontey and Nicol practise planting, but offer no arguments against sowing where circumstances are suitable. Sang says, "It is an opinion very generally entertained, that planted timber can never, in any case, be equal in durability and value to that which is sown. We certainly feel ourselves inclined to support this opinion, although we readily admit, that the matter has not been so fully established, from experiment, as to amount to positive proof. But although we have not met with decided evidence, to enable us to determine on the comparative excellence of timber raised from seeds, without being replanted, over such as have been raised from replanted trees, we are left in no doubt as to the preference, in respect of growth, of those trees which are sown, over such as are planted." (Plant. Kat. 43.) He particularly prefers this mode for raising extensive tracts of the Scotch pine and larch (p. 480.), and is decidedly of opinion, "that every kind of forest tree will succeed better by being reared from seeds in the place where it is to grow to maturity, than by being raised in any nursery whatever, and from thence transplanted into the forest," (p. 344.) Dr. Yule (Caled. Hort. Mem. ii.), in a long paper on trees, strongly recommends sowing where the trees are finally to remain. "It is," says he, "a well ascertained fact, that seedlings allowed to remain in their original station will, in a few seasons, far outstrip the common nursey raised several years older."

6829. The opinion of Dr. Yule, and in part also that of Sang, seems to be founded on the idea that the tap-root is of great importance to grown-up trees, and that when this is once cut off by transplanting, the plant has not a power of renewing it. That the tap-root is of the utmost consequence for the first three or four years is obvious from the economy of nature at that age of the plant; perhaps for a longer period;
but that it can be of no great consequence to full-grown trees, appears highly probable from the fact, that when such trees are cut down, the tap-root is seldom to be distinguished from the others. The opinion that the tap-roots have not the power of renewing their tap-root, will, we think, be found inconsistent with fact; and we may appeal to Sang and the nurserymen, who raise the oak a horse-chestnut seed. It is customary when these are sown in drills, to cut off their tap-roots without removing the plants at the end of the second year's growth, and when at the end of the third or fourth year they are taken up, there is, according to experience, no sign so strong as the first root would have been, but the remainder, but sufficient to establish the fact of the power of renewal. We may also refer to the experiment recorded by Forsyth, which at once proves that trees have a power of renewing their tap-roots, and the great advantages from cutting down trees after two or three years' planting. Forsyth" transplanted a clump of the root of one of the st st of the great di s the second year after, he headed one half of the plants down, and left the other half to nature. In the first season, those headed down made shoots six feet long and upwards, and completely covered the head of the tree; but those left alone, only grew as high as the tap-root. The other half of the plants that were not headed, were not one fourth the size of the other. One of the former is now eighteen feet high, and fifteen inches in circumference, at six inches from the ground: one of the latter measures only five feet and half in height, and three inches and three quarters in circumference. (Tr. on Pract. Plant. ed. 14.) The plant and fr. tribes receive most check by transplanting; and when removed at the age of four or five years, they seldom arrive at tree afterwards; those we should, on most occasions, prefer to sow, especially on mountainous hills and sols and situations, planting strong plants, and cutting them down two or three years afterwards, will, we think, all circumstances considered, be proved preferable to sowing.

6530. On the subject of disposing the plants in plantations, there are different opinions; some advising rows, others quincunx, but the greater number planting irregularly. According to Marshall, "the preference to be given to the row, or the random culture, rests in some measure upon the nature and situation of the land to be stocked with plants. Against steep hangs, where the plough cannot be conveniently used in cleaning and cultivating the interspaces, during the infancy of the wood, either method may be adopted. In the former manner the tap-roots will be the more easily renewed, and the propagation in more situations, we cannot allow any liberty of choice: the drill or row manner is undoubtedly the most eligible." (Plant. and Bar. Ort. p. 153.) Pontey considers it of much less consequence than most people imagine, whether the plants are planted regularly or irregularly, as in either case the tap-root will be occupied by the roots and the surface by the shoots. Sang and Nicol only plant in rows where both the horse-hoe is to be adopted. In sowing for woods and copses, the former places the patches six feet asunder and in the quincunx order. But it has been demonstrated (Farmer's Mag. vii. 406.), that the closest order in which it is possible to place a number of points, upon a plane surface, not nearer than a given distance from each other, is in the angles of hexagons with a plant in the centre of each hexagon. Hence it is argued, that this order of trees is the most economical; as the same quantity of ground will contain a greater quantity of trees, by 15 per cent, when planted in this form than in any other. (Gra. Rep. l. 297.) It is almost needless to observe, that hedge plants should be placed at regular distances in the lines, and also the trees, when those are introduced in hedges. Osier-plantations, and all such as like them require the soil to be dug every year, or every two years, during their existence, should also be planted in regular rows.

6381. The distances at which the plants are placed must depend on different circumstances, but chiefly on the situation and soil. Planting thick, according to Nicol, is the safer side to err on, because a number of plants will fail, and the superfluous ones can be easily removed by thinning. "For bleak situations," he observes, "that from thirty to forty inches is a good medium, varying the distance according to circumstances. For less exposed situations, and where the soil is above six inches in depth, he recommends a distance from four to five feet. For belts, clumps, and strips, of a diameter of about one hundred feet; the margin to be planted about the distance of two feet, and the interior at three feet. In sheltered situations of a deep good soil, he recommends a distance of six feet, and no more." (Pract. Plant.)

6832. According to Sang, "the distances at which hard-timber trees ought to be planted are from six to eight feet, and more, except the elms and sycamore, on quite a different plan, about six feet where the first four oaks are planted, supposing them at right angles, and at nine feet apart, the interspaces will fall to be filled up with five nurses, the whole standing at four and a half feet asunder. When sixteen oaks are planted, there will necessarily be thirty-three nurses planted; and when thirty-six oaks are planted, Sang observes, "the size of plants for hedral trees are planted in this manner, in a square of ten on the side, there will be two hundred and sixty-one nurse-plants required. The English acre would require five hundred and thirty-six oaks, and one thousand six hundred and ten nurses." (Plant. Kal. 163.) Pontey observes, "In general cases, a distance of six or seven feet, being certainly close enough; as at that space the trees may all remain till they become saleable as rails, spars, &c."

6833. The number of plants which may be planted on a statute acre = 160 rods, or poles, = 4840 yards = 45,500 feet, is as follows:

</table>

6834. The size of the plants depends on the site and the kind of tree; it is universally allowed that none of the resinous tribe succeed well when removed at four or more years' growth; but if the soil is of tolerable quality, prepared by digging or summer pitting, and the site not bleak, plants of such hard woods as stoe may be used whose inch or an inch more in diameter.

6835. Nicol is of opinion, "That generally trees three, or at most four, years old from the seed, and which are from twelve to twenty-four inches high, will, in any situation or soil, outgrow those of any size under eight or ten feet, within the seventh year." (Pract. Plant. 149.) The size of plants for exclusive plantations must, in some measure, depend on their kinds; but it may be said, generally, that the plants being transplanted, they should be from a foot to eighteen inches in height, stiff in stem, and well rooted. Plants for this purpose should seldom be more than three years from the seed; indeed, however, if they have been raised in good soil. Many of
them may be sufficiently large at two years from the seed; and if so, are to be preferred to those of a greater age, as they will consequently be more vigorous and healthy. The larch, if properly treated, will be very fit for planting out at two years of age. A healthy seedling being removed from the seed-bed at the end of the first year, into good ground, will, by the end of the second, be a fitter plant for the forest, than one that has been two years in the seed-bed. The best plant for the forest is that which has been nurtured in the seed-bed, and has been transplanted for one season. This is supposed to have risen a weakly plant; for, if the larch rise strong from the seed the first season, it should never stand a second in the seed-bed. The third, the eighth, and the twelfth years, the seed will, in all cases, stand the second season, will often prove sufficiently strong plants. If they be weakly, they may stand two years in the seed-bed; and then being nursed one season in good soil, will be very fit for planting out in the forest. The oak, the beech, and the chestnut, if raised in rich soil, and well furnished with roots at the end of the first year, and having been nursed in rows for two years, will be very fit to be planted out. But if they are allowed to stand two years in the seed-bed, and be planted one year in good ground, they will be still better, and the roots will be found well feathered with fine small fibres. The silver fir and coniferous trees should stand two years in the seed-bed. If transplanted into very good soil, they may be fit for being planted out at the end of the first year; but, more generally, they require two years in the lines. The Scots pine should also stand for two years in the seed-bed, and should be nursed in good ground for one year; at the end of which they will be much fitter for being planted, than if they were allowed to stand two years in the bed. They in the first instance, and in land bare of heath or herbage, they succeed pretty well; nevertheless, we would prefer them one year nursed. The above are the hardy and most useful forest trees; and from the observations made, whatever respects the age or size of other kinds, may easily be inferred. (Plant. Kal. 138.)

According to Pontey, there is no general rule to determine the size of the plants to the goodness of the soil; the best of the latter requiring the largest of the former. Still on bleak exposures this rule will not hold good, as there the plants should never be large, for otherwise the greater part would fall from the circumstance of wind-waving, and of those that succeeded, few, if any, would make much progress for several years; first of a foot, and deciduous trees of eighteen inches, are large enough for such places. As in extensive planting, soils which are good and well sheltered but seldom occur, the most useful sizes of plants, for general purposes, will be first of a foot, and deciduous trees of eighteen inches, but not more. None but good planted and well-nursed plants will stand and be of any use, and no good rooted plant, whether it have been nurseries, or even bare-rooted, none but very bad-rooted plants will fall; a large plant never has so good a root, in proportion to its size, as a small one; and hence we see the propriety of using such on good soils only. Small plants lose but few of their roots in removal; therefore, though planted in very moderate-sizes of holes, or rather slits, the roots of small plants do not suffer so much, as plants of larger size, and hence we see, that in transplanting, it is of no advantage to use small roots. But in other soils, or in lands of different kind, it is not to be forgotten, that, in being removed, a plant of two feet loses a greater proportion of its roots than a tree of one, and one of three feet a greater proportion than one of two, and so on, in proportion to its former strength and height, and thus the larger the plants, so much greater is the gain in the plant languor or weakness into which they are thrown by the operation of transplanting. (Prof. Plant. 161.)

5838. The seasons for planting are autumn and spring; the former, when the soil and situation are moderate good, and the plants large; and the latter, for bleak situations. Necessity, however, is more frequently the guide here than choice, and in extensive designs, the operation is generally performed in all moderately dry open weather from October to April inclusive. "In an extensive plantation," Sang observes, "it will hardly happen but there will be variety of soil, some parts moist and heavy, and others dry and light. The lightest will probably be planted in December or January; and the more moist, or damp parts, in February or March. It must be observed, however, that if the ground be not in a proper case for planting, the operation had better be delayed. The plants will be injured, either by being committed to the ground when it is in a sour and wet, or in a dry parched state. At a time when the soil may be termed neither wet nor dry, the operation of planting is most successfully performed. The mould then not adhering to the spade, nor does it run in; it divides well, and is made to intermingle with the fibres of the plants with little trouble; and in treading and setting the plant upright, the soil is not worked into mortar, which it necessarily must be, if in a wet state, evidently to the great detriment of the plants. It is therefore improper to plant on a retentive soil in the time of rain, or even perhaps for some days afterwards, or after a fall of snow, until it has for some days disappeared. Whereas, on a dry absorbent soil, it may be proper to plant in the time of gentle showers, immediately after heavy rains, or as soon as the snow is dissolved." (Plant. Kal. 157.)

5839. Pontey is a decided advocate for autumn preparation of the soil, and spring planting. "Autumn planting," he says, "is advisable only in few cases, while spring planting may properly be termed all the rest." (Op. cit. 417.)

5840. According to Sang, the proper time for planting the pine and fir tribes, and all evergreens, is April, or even the first fortnight in May. "Attention should be paid, that no greater number of plants be lifted from the nursery than can be conveniently planted on the same day. Damp weather is the best, and Afr. and the proper time for planting, since the roots then have their bases somewhat covered in mud (puddle) so as to be coated over by it. In all cases, care should be taken not to shake off any adhering earth from plants at the time of planting." (Plant. Kal. 341.)

5841. The operation of inserting the plants in the soil is performed in various ways; the most general mode, and that recommended by Marshall and Nicol, is pitting; in which two persons are employed, one to operate on the soil with the spade, and the other to insert the plant and hold it till the earth is put round it, and then press down the soil with the foot. Where the plants are three feet high or upwards, this is the best mode; but for smaller plants modes have been adopted in which one person performs the whole operation.

5842. Sang describes three kinds of manual operation employed by him in planting, and in part in sowing trees: by pitting; by slitting simply, or by cross, or T slitting; by the diamond dibber; by the planting-mattock; and by the planter. In filling an area with plants, he first plants those intended as the final trees, and afterwards the nurses; or one set of plants plant the former, while another follow with the latter, unless for removing the nurses, as in the case of evergreen pines and firs, should be later than that for planting the principals. (6832.) The plants, if brought from a distance, should be
The pit having been dug for several months, the surface will therefore be scourged by the rains, or probably covered with weeds. The man first strikes the spade downwards to the bottom, two or three times, in order to loosen the soil; then peaches it, as if mixing mortar for the builder; he next lifts out a spadeful of the earth, or, if necessary, two spadefuls, so as to make room for all the fibres, without their being anywhere gathered together; he then chops the rotten turf remaining in the bottom, and levels the whole. The boy now places the plant perfectly upright, an inch deeper than when it stood in the nursery, and holds it firm in that position. The man triidges in the mould gently; the boy gently moves the plant, not from side to side, but upwards and downwards, until the fibres be covered. The man then fills in all the remaining mould; and immediately proceeds to chop and poach the next pit, leaving the boy to set the plant upright, and to tread the mould about it. This in still wet soil he does lightly; but in sandy or gravelly soil he continues to tread until the soil no longer retains the impression of his foot. The man has by this time got the pit ready for the next plant, the boy is also ready with it in his hand, and in this manner the operation goes on.

On very steep hangs which have been pitted, the following rule ought to be observed in planting; to place the plant in the angle formed by the declivity and surface of the pit; and in finishing to raise the outer margin of the pit highest, whereby the plant will be made to stand as if on level ground, and the moisture be retained in the hollow of the angle, evidently to its advantage.

The all method, either simply (265.) or by the T method, is not recommended by Sang; but necessity may justify its adoption occasionally. We would not recommend planting by the slit, unless where there is no more soil than is absolutely occupied by the fibres of the herbage which grows on the place. Excepting on turf, it cannot be performed; nor should it be practised, if the turf be found three or four inches thick. By pitting in summer, turf is capable of being converted into a proper mould in the space of two or three months. This sense of pitting, especially in small plantations, can never counterbalance the risk of success in the eyes of an ardent planter. The most proper time to perform the operation of setting in the plants, is when the surface is in a moist state. On all steeps the plant should be placed towards the declivity, that the moisture may fall to its roots; that is to say, in planting, the spadehead should stand highest, and the boy lowest on the bank; by which arrangement the plant will be inserted at the lower angle of the slit.

Planting with the diamond dibber, he says, "is the cheapest and most expeditious planting of any we yet know, in cases where the soil is a sand or gravel, and the surface bare of herbage. The plate of the dibber (fig. 655, a) is made of good steel, and is four inches and a half broad where the iron handle is welded to it; each of the other two sides of the triangle is five inches long; the thickness of the plate is one fifth part of an inch, made thinner from the middle to the sides, till the edges become sharp. The length of the plate, breadth of it, and so strong as not to bend in working, which will require six eighths of an inch square. The iron handle is furnished with a turned bolt, like the handle of a large gimlet, both in its form and manner of being fixed on. The planter is furnished with a planting-bag, tied round his waist, in which he carries the plants. A stroke is given with the dibber, a little aslant, the point lying in a direction parallel with the dibber, and, by the impulse of the planters, the dibber is made to turn and cut its way through the ground: by this means a vacancy is formed between the back of the dibber and the ground; into which the planter, with his other hand, introduces the roots of the seedling plants, being careful to put them fully to the bottom of the dibber. This method will put the dibber, so as not to displacethem, and gives the eased turf a smart stroke with the heel; and thus is the plant completely formed. The greatest error the planter with this instrument can run into, is the imperfect introduction of the roots. Green, or unpurposed hands, are apt to double the roots, or sometimes to lay them across the opening, instead of planting them as it is drawn, as if it were directly from the seedling, or planting well, or two-year Scots pines, one year nursed; and the expense is much less than by the spade." (Plant. Kal. 170.)

Planting with the planting-mattock (fig. 655, c) is generally consorted to in rocky others where planting is impracticable. The heave or handle is three feet six inches long; the mouth is five inches broad, and is made sharp; the length from it to the eye, or head, is sixteen inches; and it is used to pare off the sward, heath, or other brush that may happen to be in the way, previous to easing the soil with the other end. The small end tapers from the eye, and terminates in a point, and is seventeen inches in circumference. By this instrument the surface is skinned off "for six or eight inches in diameter, and with the pick-end dagger, or the six-inch head, removing up any loose stones to the surface; by which means a place is prepared for the reception of the plant, little inferior to a pit. This instrument may be used in many cases, when the plant is to be planted on a low well, such as one-year Scotch swardings, or two-year Scots pines, one year nursed; and the expense is much less than by the spade." (Plant. Kal. 385.)

Planting with the forest-planter. (fig. 655, c) The heave is sixteen inches long, the mouth is four inches and a half broad, and the length of the head is fourteen inches. The instrument is used in plantingilly ground, or where they hand-mattock. The person who performs the work carries the plants in a close apron; digs out the earth sufficiently to hold the roots of the plant; and sets and thrives it

1 3 1 3 1 3
without help from another: it is only useful when small plants are used, and in hilly or rocky situations." (Plant. Kal. Pref. xxiv.)

684. Poncey prefers planting by putting, in general cases; the holes being made during the preceding spring or early summer. It is not so deep as for large plants to hold the roots comfortably for water. When the plants have been brought from a distance he strongly recommends puddling them (6849) previously to planting; if they seem very much dried, it would be still better to lay them in the ground for eight or ten days, giving them a good soaking of water every second or third day, in order to render them moist, and to preserve them; for the well deserves of soil sufficient to support a plant recently or immediately taken from the nursery, would, in the case of dried ones, prove so far insufficient, that most of them would die in it. The puddling here recommended may also be of great service, when plants are to be taken in small quantities (as small puddling) to tie them in bundles, or two or three hundreds each; and thus send them, by a cart-load at once, to where wanted; where such bundles being set upright, close to each other, and a little straw carefully applied to the outsides of them, may remain without damage in a sheltered situation any reasonable time necessary to plant them. Where loam soil happens to be convenient, that should be substituted in the place of straw.

6849. A puddle for trees is made by mixing water with any soil rather tenacious, so intimately as to form a complete puddle, so thick that when the plants are dipped into it may remain upon the roots for two hours, without their losing the last trace of life. This process of puddling is certainly of use, to save notice of its effects, however, in retaining, if not attracting moisture, are such that, by means of it, late planting is rendered abundantly more safe that it otherwise would be. It is an old invention, and hence it is truly astonishing that it is not more frequently practised. If we could but persuade people to adopt it generally in spring planting, I believe the prejudice in favor of autumn practice would soon be done away. (Prof. Plant. 167.)

6850. Poncey's methods of planting are in general the same as those of Sang: he uses a mattock and planter of similar shape; and also a two or three pronged instrument, which we have elsewhere denominated the planter's hack. (1305. fig. 80.) "This instrument," he says, "has been introduced of late years as an improvement on the mattock and planter (fig 653. b, c), being better adapted to soils full of roots, stones, &c.; they are likewise easier to work, as they penetrate to an equal depth with a stroke less violent than the mattock; also less subject to get clogged up, if the earth be hard. But the puns of both should be about eight inches, and the distances between them, when with three prongs, one and a half, and with two prongs, about two inches; the two-pronged hack should be made somewhat stronger than the other, as it is being chiefly intended for very stony lands, or where the soil breaks in order to separate it from the herbage, &c. These tools are chiefly applicable to plants of any size up to about two feet, or such as are generally used for great designs, where they are used as a substitute for the spade, in the following manner: The planter being provided with a basket holding the plants required (the holes being supposed prepared, and the earth left in them), he takes a tree in one hand, and the tool in the other, which he strikes into the hole, and then pulls the earth towards him, so as to make a hole large enough to hold all its roots; he then puts in the plant with the other, and pushes the earth to its roots with the back of the planter; after which, he fixes the plant, and levels the soil at the same instant with his foot: so that the operation is performed by one person, with a degree of neatness and expedition which no one can attain to who uses the spade. It is known to all planters, that but few laborers ever learn to plant well and expeditiously in the common method, without an assistant: this method, however, requires neither help, or many years of experience, and any laborer of common sagacity, or boy of fifteen, or even woman, may learn to perform it well in less than half an hour. The facility with which these tools will break clods, clear the holes of stones, or separate the soil from herbage, the roots of heath, &c. (the former being previously mellowed by the frost,) may be easily imagined." (Prof. Plant. 173.) The adoption of a small mattock for2 inserting plants, we recollect to have once recommended in a tract on planters in the Highlands, by Mac- taurin, a nurseryman, published at Edinburgh upwards of twenty years ago.

6851. An expeditious mode of slit planting is described in the General Report of Scot- land, as having been practised for many years on the Duke of Montrose's estate. It is as follows: "The operator, with his spade, makes three cuts, twelve or fifteen inches long, crossing each other in the centre, at an angle of sixty degrees, the whole having the form of a star. (fig. 630.) He inserts his spade across one of the rays (a), a few inches from the surface, and on the side next himself; then bending the handle toward him, and taking hold of it just from the bottom, and almost to the ground, the earth opening in fissures from the centre in the direction of the cuts which had been made, he, at the same instant, inserts his plant at the point where the spade intersected the ray (a), pushing it forward to the centre, and ascertaining its placing through the fissures. His next operation is to move his spade, have pressing it into a compact state with his heel; the operation is finished by adding a little earth, with the grass side down, completely covering the fissures, for the purpose of retaining the moisture at the roots; and likewise a top-dressing, which greatly encourages the plant to push fresh roots between the eawards." (Vol. II. p. 268.)

CHAP. IV.

On forming Plantations, in which Ornament or Effect is the leading Consideration.

6852. In designing ornamental plantations, the situation, form, the disposition of the trees, and the kinds employed, are the principal considerations.

6853. The situations to be planted, with a view to effect, necessarily depends on the kind of effect intended; these may reduced to three — to give beauty and variety to general scenery, as in forming plantations here and there throughout a demesne; to give form and character to a country-residence, as in planting a park and pleasure-grounds; and to create a particular and independent beauty or effect, as in planting an extensive area or wood, unconnected with any other object, and disposing of the interior in avenues, glades, and other forms. In the two first cases, the choice of the situation must always be relative to other objects; as, for example, in ornamenting general scenery, to fields and enclosures, buildings, roads, &c.; and to the mansion-garden and other parts of a residence, in laying out a country-seat: but in forming independent plantations the choice may be absolute, and guided by no other consideration than the effect to be produced. One of the greatest beauties produced by planting, either on general scenery, or on the grounds of a residence, is that of varying the form of the surface of the country
or increasing the variations already existing. To do this with most effect, it is an obvious and long established principle, that, other circumstances being the same, the hills are to be more generally planted than the hollows, or even the plains. By planting a hill, or the least rise of ground, that hill or rise is increased in effect; but by planting the low grounds between hills or protuberances, their effect is destroyed. It is to be observed, however, that the latter practice is often what we observe in natural scenery. In hilly tracts in a state of nature, and under the dominion of no other animals than cattle or sheep, the vales or dells (fig. 637.) are generally filled with wood and the tops of the hills bare, which, however agreeable to those who view or study nature chiefly in detail, yet to the general observer it tends to confound form, and introduce monotony of surface. Art, therefore, when planting for general effect, or for heightening the character of surface, adopts a contrary practice (fig. 638.) to what is general in

wild nature; for few things in a wild state are suitable to the views of man in a state of civilisation and refinement; and when he admires rude scenery, it is from views of its novelty or rarity in cultivated countries; or with reference to some other art or object, or state of the same object. At the same time, a hill crowned with wood occurs in nature occasionally, both with and without naked hollows or plains at its base, and never fails to excite a superior degree of satisfaction or pleasure in the spectator. To plant hills, therefore, in preference to valleys, may justly be designated an imitation of one of the more interesting features of nature.

6354. With respect to form, it may be absolute, or independent of every consideration but the taste of the designer; or it may be relative. It is absolute in plantations intended to create particular beauties within themselves; as in labyrinths, woods pierced with avenues, stars, &c., in the geometric style; or in compositions and groups, thickets and glades in the interior of a wood, laid out in the modern manner. It is relative to the shapes of the ground and to existing objects in the forms adapted for improving general scenery; and to these considerations, and to the situation and form of the mansion, gardens, waters, &c. in laying out the grounds of a country-residence. For either of these objects the general principles of operation are to heighten beauties already existing; to conceal defects; if possible, to create beauty; and to connect detached objects, either in reality or appearance, so as the scenery, from whatever point it may be viewed, may appear a whole; in short, the end is a harmonious and expressive whole, and the means are the grouping and connecting of the parts. Some tracts of country, or those parts of a desmesne exterior to the park, may be deficient in woodiness; there trees may be introduced in masses on elevated sites, or the sides of hills; in groups connected with buildings; in thinly scattered trees, in pastures, and by brooks; and in rows in hedges, and by other fences or roads. Where disagreeable objects are to be concealed, the course is evident; and where nothing is interesting, attempts must be made to create interest. A road through a dreary country may often have much of its dullness taken away by one or two rows of trees on each side, the stems of which will break and vary the distant scenery. The lines may vary in form and direction, may swell into strips, or clumps, or thickets; form recesses, or be interrupted, according to circumstances. The route through some of the most dreary tracts in Germany and Russia, and the well-known Strada di Campagna, in Italy, are in this way rendered tolerable. In all this, though the main object may be beauty, yet, utility must never be lost sight of. All plantations by arable lands should, as much as possible, be bounded by straight, or at least not very irregular lines, and connected with the hedges or other fences already existing; few single trees or groups should be planted in the area of such fields. In pastures, the worst walls and most exposed situations should be chosen, and such forms adapted as may shelter the stock from all quarters, but especially from the storms and winds which more generally prevail. In planting near cottages and villages, care should be taken not to render the atmosphere unhealthy by stagnating the air, or to lessen the value of their yards and gardens by curtailing their extent, or by excess of shelter and shade. Roads or lanes should on no account be injured, nor the water of streams and ponds rendered dark, discolored by leaves, and unwholesome to men or cattle. In short, the planter, for effect, should never lose sight of utility, or plant in opposition to it; for though he may produce particular sorts of beauty, and especially that lately so fashionable and justly admired disposition of objects, called picturesque, which may be admired by a number for a time; yet there is a much more elevated and universal beauty, that of moral relation, or, in short, refined utility, which, while men...
retain their social feelings, must ever be the most interesting to mankind in general, and will therefore finally prevail.

6855. The outline of plantations, made with a view to the composition of a country-residence, is guided by the same general principles; whether the trees are to be disposed in regular forms, avowedly artificial; or in irregular forms, in imitation of nature. (Fig. 639.) The first thing is, in both modes, to compose a principal mass, from which the rest may appear to proceed; or be, or seem to be, connected. In common cases it answers best to include or connect with this mass the house, kitchen and flower-gardens (e); from these other masses and groups should proceed, either connected, or better, only seemingly so when viewed horizontally. Their forms should be such

and so disposed, relatively to the ground and other objects, and to each other, as to throw the pasture surface into broad masses (a, b, c, d), which become wholes in their turn, and their connection and variation is heightened by the variety in the glades between the masses and groups of plantation. Such would be the mode of procedure on a flat to be formed into a modern park; regard being had to exclude or admit the view of certain parts of the distant scenery; never to shut in, or leave without a third distance (as is the term in landscape-painting), any of the scenes within the boundary of the park; and to other laws of perspective, optics, and composition, which will be more fully entered on in treating of landscape-gardening.

6856. In the pleasure-ground, which, as far as respects the form or ground outline of plantations, is to be considered as a part of the park, the same principles are applicable. In neither the artificial or natural style, should their width be great; but their form may be varied at pleasure, subject to general principles. Where the ground is irregular (Fig. 640.), only the modern style can be adopted with good effect; and there, by conducting the walks, or forming the water chiefly in the hollows (a), and planting the eminences (b), varying the manner in which the outlines of these masses embrace the declivities, the happiest effects may be produced. Deviations from these general principles can only be justified by extraordinary circumstances.
6857. With respect to the extent, or area, occupied by ornamental plantations, as such, that need seldom be great. They are generally seen only in profile, and therefore a circuitous outline (fig. 641. a.) may on most occasions be contrived to have the same effect as planting a solid mass, which will occupy much more ground (b), show less exterior variety, and none within. The case is different, however, where the upper surface of a plantation is to be met by the eye, at a large angle, say upwards of 35°. In that case, to produce a grand and imposing effect, real extent is wanting. Examples occur in planting the steep sides of high hills, to be seen from below; or valleys or plains to be seen from great elevations. It must be confessed that these are among the grandest circumstances in which wood can be viewed; profiles of outlines, varied both as respects the sky and the ground, are beautiful and interesting; and avenues and long rows of trees form imposing perspectives; but the side of a range of mountains clothed with wood, seen at a certain distance, from a plain below or opposite hills, is one of the most magnificent of rural prospects.

6858. With respect to the disposition of trees in a plantation where art is avowed or purposely displayed, the more regularly the plants are placed the better is the end attained; but where nature is to be imitated, irregularity will best sustain the character. This should be studied in the larger as well as the smaller plantations, in the natural style; but more especially in detached groups, which operate so powerful an effect in laying out the grounds of a residence. The greatest beauty of a group of trees as far as respects their stems, is in the varied direction these take as they grow into trees (fig. 642.); but as that is for all practical purposes beyond the influence of art, all we can do is to vary as much as possible the ground-plans of groups, or the relative position which the stems have to each other, where they spring from the earth. This is considerable, even where a very few trees are used, and of which any person may convince himself by placing a few dots on paper. Thus, two trees (fig. 643.); or a tree and shrub, which is the smallest group, may be placed in three different positions with reference to a spectator in a fixed point: if he moves round them they will first vary in form separately, and next (at b) unite in one or in two groups, according to the position of the spectator. In like manner three trees (fig. 644.) may be placed in four different positions; four trees may be placed in eight different positions (fig. 645.); five trees may be grouped in ten different ways as to ground-plan (fig. 646.); six may be placed in twelve different positions (fig. 647.); and so on.

6859. In planting groups it is not meant to be asserted, that the ground-plan of each should be studiously considered; it will be sufficient if this is done in conspicuous situations, by the sides of walks and roads, and in such places as require for shelter or shade, or to exclude some disagreeable object, a series of groups of nearly the same number of trees. For the ordinary purposes of grouping, such as varying the apparent outline of masses, connecting scattered objects, adding parts to such objects as are incomplete wholes, &c., it will be sufficient to introduce large and small groups; never to put two trees at exactly the same distance from each other; three in the angles of an equilateral triangle; four in those of a square; five in those of an octagon, and so on.
6860. **Scattered trees.** It has been a very common practice among planters to introduce, in parks, great numbers of detached single trees (in vulgar technology, dotting), with a view of effecting, by them, what can only be done by groups. Excepting the clump, there is not a greater deformity in the grounds of British country-residences. Supposing these trees, planted on a level surface, all of the same sort, and all growing equally well, their insipid sameness of form and position must be evident to the mind’s eye of every one. Suppose them on the same character of surface, but all, or chiefly, of different sorts (fig. 648.), it is equally evident they will grow with different degrees of vigor, and assume different characters of stem and head; and consequently produce an appearance of the most discordant kind. It is only necessary to analyse a group, to be

convinced of the variety of general form produced, even by trees of one species, but more especially by two kinds, and this, even by specimens that would be unsightly apart; and to observe a portion of the scattered woody scenery, in the openings or glades of a natural forest, to be convinced how much more variety is produced by that manner of planting, than by distributing over a surface great numbers of single trees. It is observed by Uvedale Price, that in the numerous landscapes which compose the *liber veritatis* of Claude, there is not more than one single tree; so highly did this artist value the principle of connection. A single tree, however, is not always to be condemned, even as such, for its form, age, or blossom, or some other accidental circumstance may compensate for its isolated situation; and it may often exist singly as a tree, and yet in connection or grouped with other objects, as buildings, rocks, &c.; and in these cases it is not to be condemned, because the grand object of grouping, connection, is maintained by the co-tangent object.

6861. **Placing the groups.** Another practice in the employment of groups, almost equally reprehensible with that of indiscriminate distribution, is that of placing the groups and thickets in the recesses, instead of chiefly employing them opposite the salient points. The effect of this mode is the very reverse of what is intended; for, instead of varying the outline, it tends to render it more uniform by diminishing the depth of recesses, and approximating the whole more nearly to an even line. The way to vary an even or straight line or lines, is here and there to place constellations of groups against it (fig. 649. c); and a line already varied is to be rendered more so, by placing large groups against the prominences (a) to render them more prominent; and small groups (b), here and there in the recesses, to vary their forms and conceal their real depths.

6862. *In all plantations in the natural style* above the size of a group, the same general principles are to be followed in the disposition of the trees; the plants, whatever be their kinds, and whether the mass is finally to assume the character of a wood, grove, or copses, should be placed irregularly; here thick, and there thin, as if they had sprung up from the accidental semination of birds or winds. “The effect of this arrangement will not be that composition of low and high, oblique and upright stems, and young and old trees, and low growths, which we find in forest scenery; but it is all that can be done in imitation of it at the first planting; and subsequent thinning, pruning, and cutting down, moving, *renversing*, planting, and sowing, must be used from time to time to complete imitation or allusion, unless the owner will rest satisfied with an inferior degree of beauty.”

6863. **The general form of tree employed** materially influences the effect of plantations. The capacities of different trees for producing effects in landscape, and the general division of trees into round-headed, oblong-headed, and spiry-topt, have been already pointed out (6795. et seq.). It has also been observed (6837.), that the greater number of plantations are seen chiefly in profile; and hence, that the outline which the tops of the trees form against the sky or the back-ground, is the most conspicuous feature in their aspect. The difference between this outline, when formed of *spiry-topt trees*, as the firs, pines, &c. (fig. 650.); of *oblong-headed* trees, as most of the willows, alders, poplars (fig. 651. b); and the round-headed sorts, as the oak, ash, elm, and most trees (fig. 651. a)
is so considerable, as to merit the particular attention of the planter. Nothing can be more harsh and unvaried than the serrated outline of the fir tribe, whether planted in rows, strips, or masses; whereas the rounded-headed trees, even in single rows, produce some variety of sky outline. The difference is equally great between the face or front surface of a row or mass of spiry and round-headed trees; for the great regularity and similarity of the branches of the former, precludes the possibility of breaks in form, or light and shade, and presents one uniform surface of verdure, not unlike the side of a high hedge. The front surface of a row or mass of round-headed trees, on the contrary, from opposite qualities in the branches, produces prominences and recesses of different degrees of magnitude, and of different forms and relative positions. If we look on the upper surface of a plantation of each class, we shall find the difference equally great.

6864. The situations where spiry-topt trees have most effect is among rocks, and in very irregular surfaces; and especially on the steep sides of high mountains (fig. 652.), where their forms, and the direction of their growth, seem to harmonise with their pointed rocky summits. Fir and pine forests are dull, gloomy, and monotonous in the sandy plains of Poland and Russia, but among the broken rocks, craggy precipices, and otherwise endlessly varied surfaces of Sweden and Norway, they are full of variety. In tame countries they present most variety when planted so thin as barely to touch each other, and when a number of them are kept low, where the whole are of different ages (fig. 653.) But the variety produced, even by this disposition, is still far short of what would be effected by a similar arrangement of round or oval-headed trees (fig. 654.), of different ages, or mixed with shrubs or low growths. The most suitable situation for spiry-topt trees, in ornamental scenery, is as single objects or in small groups (fig. 655.), sparingly introduced in the margin of thickets or strips, or sprinkled along the bottoms of dells or dingles. In plantations which comprise masses of all the different species of hardy tree, there they may come in also in their proper place; and in mountain and rocky scenery, they are in the places which nature seems to have intended for them.
6865. The oblong-headed trees may be introduced much more frequently than the spirey-topped sorts; the more obuste summits blend well with the round-headed trees, and the more acute topped sorts which terminate in flexible flame-like shapes, as the Lombardy poplar, and cypress, form excellent contrasts to the round trees, and serve as transition forms to the spiry tribe. The round-headed trees, it need hardly be observed, are the most general in nature, at least in temperate climates, and are the most universally applicable in ornamental planting. These considerations on the forms of trees refer to them chiefly as in independent plantations; in connection with buildings, the effect, as to form, may often be influenced by that of the building, and also by the effect or object intended by planting them.

6869. With respect to magnitude, the grand division of woody plants is into trees and shrubs. The bulk and heights of the common trees and shrubs of the country being generally known, the eye estimates the magnitude of other objects by theirs; consequently extraordinary magnitudes, whether large or small, should always be used under extraordinary circumstances: apparent size, proportion, and distance of objects, might otherwise be deranged, and a discordant effect produced. Shrubs, which have the form of trees; and low trees, as the mountain ash, the apple and pear, often produce this effect, when planted as single objects; and unless their fruit is prized above every thing else, they should, when introduced for the sake of their flowers, either be planted in the margins of plantations, or grouped in couples, or in the ordinary size. The finest small groups are of this description, or composed of common deciduous timber trees and hardy shrubs, as oaks, chestnuts, hollies, thorns, &c.

6871. The choice of species must be made subservient to general effect, and to the particular purpose, for some species are more applicable than others. These have their uses (chap. i.), and both should be continually present in the mind of the planter. For the more general purposes of planting, the native timber of the country, native or naturalised, are mostly to be preferred, as generally producing trees, whose natural form, and proportions, are exactly adapted for the object in hand, and not to answer to the eye. Foreign trees also contribute greatly to variety and interest, and therefore are indispensible in pleasure-grounds, or other scenes of much resort. "Any number of species may be admitted into improved grounds; commencing with the rare sorts near the house, as the centre of art and refinement, and expounding to the country the common trees of the country at such distances as the extent and style of the place may suggest. The proportions of such trees as are only ornamental, and such as are valuable as timber, must be in some degree determined by the character of the place, but chiefly by the taste and view of the owner. Beauty alone, without utility, will not long please; and a few single groups and plants of the rare species, in the grounds more immediately connected and connected with will generally afford more satisfaction than a lavish display of exotics; the former will always present a more luxuriant and thriving display of scenery than the latter, and sooner attain the maturity of beauty."

6876. Whatever number of species are used, one only should prevail in one place; or if there be high or low growths, then one of each kind should prevail. Great attention should be had that the species which compose the groups and thickets, or other scattered woodinesses which border on masses, should consist entirely of the species which prevail in the masses; if this precaution neglected, heads of these appendages producing connection and harmony, they will have a tendency directly to the reverse. Thickets may next be considered in regard to their form, that is, the form of their ground-plan; and with groups and single trees in regard to the choice of species. Thickets are produced by nature, by the inroads of cattle. But let the herbaceous under growth be removed, and let the trees be preserved, as also the side on which they abound is more deeply than the other. The plan of the thicket, therefore, varies accordingly. In elevated grounds, exposed to a particular wind, the thickets will exceed in length, which will be found generally to be in the direction of the storm. The cause is too obvious to be pointed out; but this effect, and every other observed in the groups and thickets of natural scenery, always merit study, and most frequently deserve imitation in creations of landscape-scenery. The species of tree ought obviously to be those of the part of the mass to which they belong; for thickets, groups, and single trees, ought to resemble disjointed and broken fragments from those masses. But in particular cases, for rendering a prominenee still more prominent, or increasing the depth of a recess, a few plants of similar, or not discordant growths, but of darker or lighter greens, may at a distance add to the effect of each. By the same process, with more contrasted species, where no other mode can be put in execution, the formality of a single row may in some degree be varied in its situation and contour.

6890. The arrangement of the species to effect variety most evidently be by grouping or collecting them in masses; for if all the species made use of were intimately mixed together in every part of a plantation, it is evident the eye would meet everywhere the same species; so that, as far as variation from that source was sought for, it would be entirely wanting. Uvedale Price has treated this subject with much ingenuity; and in reproducing the common practice of mixing as many different sorts as can be procured, in order to produce variety, observes, that "variety, of which the true end is to relieve the eye, not to perplex it, does not consist in the diversity of separate objects, but in the diversity of their effects when combined together in a different composition and character. Many think, however, that they have obtained that grand object, when they have exhibited in one body all the hard names of the Linnean system, and thus covered the ground plants as well as the larger sorts of vegetation. In some plantations, the result is a sameness of a different kind, but not less truly a sameness that would arise from there being no diversity at all; for there is no having variety of character, without a certain distinctness, without certain marked features. Thus," he has observed, "there is more variety in passing from a grove of oaks to a grove of firs than in passing through a wood composed of a hundred different species, as they are usually mixed together. By this indiscriminate mixture of every kind of tree in planting, all variety is destroyed by the excess of variety, whether it is adopted in belts or clumps, as they have been technically called: for example, if ten enormous belts of trees are to be planted, clumps be composed of ten different sorts of trees in each, they become so many things exactly similar; but if each clump consists of the same sort of trees, they become ten different things, of which one may hereafter furnish a group of oaks, another of elms, another of chestnuts or of thorns, &c. In like manner,
In the modern belt, the recurrence and monotony of the same mixture of trees of all the different kinds, through a long drive, make the more tedious in proportion as it is long. In part of the drive at Woburn, there is a belt in which is a circumstance of grandeur, of variety, of novelty, and, I may add, of winter comfort, that I never saw adopted in any other place so magnificently a scale; the contrast of passing from a wood of deciduous trees to a wood of evergreens must be felt by every one. Another sort of planting, though in weaker degree, would be felt in the course of a drive, if the trees of different kinds were collected in small groups or masses by themselves, instead of being blended indiscriminately."

651. Sir W. Chambers and Price agree in recommending the imitation of natural forests in the arrangement of parks, by the scattering of saplings and the opening of a space round the parent in masses or breaches, depending on a variety of circumstances, but chiefly on the facility which these seeds afford for being carried to a distance by the wind, the rain, and by birds or other small agents. Every sort of species is introduced, the different sorts from different species, according to the soil and situation; and arrive at maturity, maturing with other plants and trees, and with the browsing of animals. At last, that species which had enjoyed a maximum of natural advantages is found to prevail as far this maximum extended, stretching along in masses and angular portions of surface, till circumstances changing in favor of some other species, that takes the prevalence in its turn. In this way it will generally be found, that the number of species, and the extent and style of the masses in which they prevail, bears a strict analogy to the changes of soil and surface; and this holds good, not only with respect to trees and shrubs, but to plants, grasses, and even the mossy tribe.

652. The most perfect arrangement of species in regard to variety would be to employ every kind of tree and shrub that will grow freely in the open air, and arrange them according to the natural system. We have already suggested (6144.) that a residence might be wooded in this way, so as in the smallest extent to obtain a maximum of variety and beauty. In most cases, where grouping, or any systematic plan of arranging the species is to be adopted, the form of the field or ground on which they are planted, and the object of the planting, and the kinds for each form written down in a corresponding list; the small detached masses intended as thicket (f) should be similarly marked, the situation of groups indicated either by Use (2), or by small clumps, (6, 3) referring to a list of kinds; and where shrubs are to be introduced in the groups, two figures may be used ($\frac{1}{2}$, $\frac{1}{2}$), one of which shall indicate the kind of tree, and the other the species of low growth or shrub. This mode we have already described for ornamental planting, and find it enables gardeners to execute them with perfect accuracy.

653. The size of the plants used in ornamental planting should be as great as the soil and situation will admit, for two reasons: first, because an early effect is always desirable in beauty, because in planting detached groups, obtained in large and small plants, and a varied inclination of their stem (fig. 632.) may be introduced in imitation of nature. Small groups on pastured lands, indeed, cannot be formed without trees whose stems are sufficiently high to raise their heads out of the reach of cattle, without enclosing so considerable a space round every tree as to render this mode both tedious, unsightly, and expensive.

654. Fences. Masses, in the ancient style of planting, were generally surrounded by walls or other durable fences. Here the barrier was considered as an object or permanent part of the scene, and for that reason was executed substantially, and even ornamentally. They were generally walls substantially coped, and furnished with handsome gates and piers. The rows of avenues and small clumps, or platoons intended to be finally thrown open, were enclosed by the most convenient temporary fence.

655. In planting in the natural style, a regular fence either of verdant or masonic materials, can never be the final part of perfect imitation, since no such thing is to be found in nature. But in planting in farming-lands, or for the purpose of improving the general scenery, some permanent fence is requisite; and that can be said is, that which promises in the end to be the most efficient and economical, will almost always consist of a wall, and is usually surrounded by water or cut in the same with trees, sometimes of the same, sometimes of different sorts, and stantly nearly full of water, here present themselves as the most general kinds. Any fence, however, of which a large excavation, without water, forms a part, as the sunk fence, should be used with great caution; as there are none of this class but what look ill from at least one point of view, that is, when seen lengthways.

656. In planting to form a park or residence, with the exception of the boundary fence, and that which separates the lawn or mown surface from the grazed scenery, no permanent barrier of a formal nature should ever be admitted. In very bleak situations, walls or mounds of earth, however unsightly, may be necessary for a time to shelter and draw up the plants; but the final removal of these and all fences in parks, should be looked to as certain. Light palings, the rails coated over with tar or pyrogenous acid, and the posts charred by burning at the lower end, to render them durable, may be used in the greater number of cases; and in many, where the plants are larger, and the soil and other circumstances favorable to their growth, hurdles or other moveable rails or palings may be used. "The present improved state of the manufacture of iron offers a very desirable accommodation in this respect, affording the best guards for single plants and groups; and iron hurdles, or lines of cast-iron standards and half-inch wires, as rails for hedges, have a light and temporary appearance, highly congenial to the idea of their speedy removal. The lines of the fences conforming to the irregular shapes of the masses will not be disagreeable to the eye, if those of the latter are arranged with any regard to apparent connection; for any object of beauty in the garden, however ornamental, the beauty of the fence, the peculiarity of the stem, and even character, when connected and arranged in such a way as to form a whole. When a plantation is finally to be composed both of trees and undergrowths, thorns, sallows, hollies, herberries, and briars, may, in many cases prevail in the margin; which, when the fence is removed, will form a picturesque phalanx, and lend interest to the scene. The cattle, which, by introducing irregularity and heighten the variety and intricacy of such masses." (Edin. Encyc. art. Landscape Gardening.) In this way, as Price observes (Essays, vol. i.), the planter may plant as thick as he chooses, and never think of thinning or future management, only taking care to introduce no more trees than he intends to remain finally as timber. The great majority of trees will be planted by the hand of the gardener, or perhaps by the use of hedge-rooms, will grow up in free and unconstrained shapes. The future care of plantations is so generally neglected, that this suggestion, under certain circumstances, well merits adoption; though it certainly has no pretension to be called a scientific or profitable mode of planting. It is what it pretends to be, a picturesque mode.
PRACTICE and FOR

 Though every one knows, the progress and products of trees, like those of other plants, may be greatly increased or modified by cultivating the soil, pruning and thinning.

With respect to culture of the soil, it is evident that young plantations should be kept clear of such weeds as have a tendency to smother the plants; and though this is not likely to take place on heaths and barren sites, yet even these should be looked over once or twice during summer, and at least those weeds roots which have been previously introduced among newly planted trees; though it must not be forgotten that relatively to the trees, the plants composing such crops are weeds, and some of them, as the potato, weeds of the most exhausting kind.

In preparing land for sowing woods, Sang ploughs in mixture, sows in rows six feet apart, and crops in between, with low-growing early potatoes, turnip, lettuce, or other green crops. He does not approve of cropping the intervals with young trees, as a sort of nursery, as they prove more scouring crops than esculent vegetables, nor with grain, as not admitting of culture, and being too exhausting for the soil.

Marshall, and some other authors, however, approve of sowing the tree-seeds with a crop of grain, and hoeing up the stubble and weeds when the crop is removed.

Wherever preparing the soil for planting is thought necessary, that of cultivating it for some years afterwards will generally be thought the same; for where quick growth is essential, cleanliness of appearance, especially of consequent crops of potatoes, with short tops, or turnips, may be admitted into such plantations with advantage for two or three years, as they create a necessity for annually digging or stirring the surface, and tend very materially to accelerate the growth of the trees. If objected, such crops, made in the same season with hard wood, are likely to have a very beneficial effect, the fact, so far as common vegetables are concerned; but as to the production of wood, its support depends, in a great measure, on a different species of nutriment; and hence, I could never observe that such cropping damaged it materially. (Profi. Plant. p. 153.)

Osier-plantations for basket-willows and horse-hoed and cleaning ditch, are the whole course of their existence; and so do hedge-rows, to a certain extent, and some ornamental plantations.

Filling up blanks is one of the first operations that occurs in the culture of plantations next to the general preparation of the soil, and the entire filling up of the empty spaces after pitting, either in the mass form or ordinary mixture, should remain several years after planting, before filling up the vacancies, by the death of the hard-wood plants, takes place. Hard-wood plants, in the first year, and even sometimes in the second year after planting, die down quite to the surface of the ground, and are apparently dead, while their roots and the wood immediately above them, are quite fresh, and capable of producing very vigorous shoots, which they frequently do produce, if allowed to stand in their places. If a tree, such as that above alluded to, be taken out the first or second year after planting, and the place filled up with a fresh plant of the same kind, what happened to the former may probably happen to the latter; and since the period of a spot may be protracted to a great length of time; or it is possible this object may never be gained.

The filling up of the hard wood kinds in a plantation which has been planted after trenching, or summer-fallow which has been kept clean by the hoe, may be done with safety at an earlier period than under the foregoing circumstances; because the trees, in the present case, have greater encouragement to grow vigorously after planting, and may be more easily ascertained to be entirely dead, than where the natural heritage is allowed to grow among them.

But the filling up of trenches and pines may take place the first spring after the plantation has been made; because such of these trees as have died are more easily distinguished. In many cases when a larch or a fir loses its top, either by dying down, or the biting off branches, and rabbits, the most vigorous lateral branch is detached from the stem, by the rabbit which they strip, which regrows, and is capable of producing very vigorous shoots, which frequently do produce, if allowed to stand in their places. If a tree, such as that above alluded to, be taken out the first or second year after planting, and the place filled up with a fresh plant of the same kind, what happened to the former may probably happen to the latter; and since the period of a spot may be protracted to a great length of time; or it is possible this object may never be gained.

The introduction of two or three plants, from a foot to three feet in height, at a particular deficient place, can never, in the above circumstances, be attended with any advantage. Such plants may indeed become rooted, and may answer well enough in the character of underwood, but they will for ever remain in ground for any other purpose. It is highly improper, then, to commence the filling up of hard-wood plantations before the third year after planting; or to protract it beyond the fifth or the sixth. March is the proper season for this operation. (Plant. Kalendar. 253.)

Pruning is the most important operation of tree culture, since on it, in almost every case, depends the ultimate value, and in the actual bulk of timber produced. In the purposes of pruning, as for most other practical purposes, the division of trees into resinous or frondose-branched trees, and into non-resinous or branchy-headed sorts, is of use. The main object in pruning frondose-branched trees is to produce a trunk with clean bark and sound timber; that in pruning branchy-stemmed trees, is principally to direct the lignaceous matter of the tree into the main stem or trunk, and also to produce a clean stem and sound timber, as in the other case. The branches of frondose trees, unless in extraordinary cases, never acquire a timber size, but rot off from the bottom upwards, as the tree advances in height and age; and, therefore, whether pruned or not, the quantity of timber in the form of trunk is the same. The branches of the other division of trees, however, when left to spread out on every side, often acquire a timber-like size; and as the lignaceous matter they contain is in general far from being so valuable as when produced in the form of a straight stem, the loss by not pruning off their side branches, or preventing them from acquiring a timber-like size, is evident. On the other hand, when they are broken off by accident, or rot off by being crowded together, the timber of the trunk, though in these cases increased in quantity, is rendered knotty and rotten in quality.
6885. *With respect to the manner of pruning, where straight timber is the object, both classes in their infancy, as Sang observes, should be feathered from the bottom upwards, keeping the tops light and spiral, something resembling a young larix.* (Fig. 657, a) *The proportion of their tops should be gradually diminished, year by year, till about their twentieth year, when they should occupy a third part of the height of the plant; that is, if the tree be thirty feet high, the top should be ten feet (6). In all cases in pruning off the branches, the utmost care must be taken not to leave any stumps sticking out, but to cut them in to the quick. It is only by this means that clean timber can be procured for the joiner; or slightly smooth-stemmed trees to please the eye. It is a very general practice to leave stumps or stumps (6); before the hole can be enlarged sufficiently to cover these, many years must elapse; the stumps in the meantime become rotten; and the consequence is timber which when sawn up (6) is only fit for fuel. 6886. Pontey says, "The sap of a tree may be considered as the raw material furnished by nature; and man, the manufacturer who moulds it into the form most useful for his purpose. A moderate quantity of leaves and small wood is necessary to every tree; but all above that quantity are of no use to the plant, and of little value to its owner." (Forest Pruner, 152, 153.)

6887. *Pruning for ornament or beauty must be guided in its operations by what that beauty is. If it is the beauty of art, then the trees may require to be cut or clipped into the shape of animals (Fig. 645); or inanimate natural objects, as mounds of earth, mushrooms; or geometric forms, triangles, globes, cones; or elaborate mounds, as terraces, theons, temples, theatres, or other architectural or sculptural compositions. (Fig. 658.) The dwarfing of trees is also another kind of artificial beauty, much practised by the Chinese; and though the habit be kept up chiefly by withholding nourishment; yet the dwarf is produced by bringing a branch; enveloping it in a ball of loam; amputating it when it has made roots; and then pinching off or exuberated shoots, as to keep it into shape. (Livingstone, in Hort. Trans. iv. 224.)"

6888. If natural beauty is desired, then the pruning must be rather negative than positive; the object being to let the tree assume its natural shape, or, as Sang describes it, "express its own nature. All that man can do, therefore, in the way of pruning for this object, is to assist a plant of the tree kind to express the characteristics of a tree; this is, a powerful trunk and ample spreading head, which distinguishes it from a shrub; and this he does by clearing a part of the tree of its side branches; and by avoiding to train up a shrub with a single stem like a diminutive tree. In attending to these instructions the great importance of the use of the leaves must never be lost sight of: this is not, as Pontey asserts, to attract the sap, but to propagate it when propelled to them, and thus form the extract or food taken in by the plant, into a fluid analogous to blood, and which is retained so formed by the leaves into the inner bark and sapwood. It must be a very nice point, therefore, to determine the quantity of branches or leaves that should be left on each tree; and if no more are left than what are necessary, then in the case of accidents to them from insects, the progress of the tree will be doubly retarded. Experience alone can determine these things. Both Pontey and Sang agree that "strength is gained as effectually by a few branches to form a head as by many."

6889. The general seasons of pruning are winter and spring, and for the gem midsummer, as it is found to gum very much at any other season. Pontey says, "as to the proper season for pruning, there is only one difficulty; and that is discovering the wrong one, or the particular time when trees will bleed. Only two trees have been found which bleed uniformly at certain seasons, namely, the sycamore and firs, which bleed as soon as the sap begins to move. In spring pruning, desist when this takes place." As a general rule, he thinks "summer preferable to winter pruning; because, in proportion as wounds are made early they heal so much the more in the same season." (Forest Pruner, 256.)

6890. Sang suspends pruning from the end of February to the middle of July, but carries it on during every other month of the year; the gem, or any other tree very apt to gum, he prunes only in July and August. (Plant. Kat. 268.)

6891. *With respect to the implements to be used, Sang observes, "In every case where the knife is capable of lopping off the branch in question, namely, in the pruning of infant plants, it is the only instrument necessary. All other branches should be taken off by the saw. A hatchet, or a chisel, should never be used. Every wound on the stem, or bole, should be quite into the quick, that is, to the level and depth of the bark; nor should the least protuberance be left. The branch to be lopped off by the saw should, in all cases, be notched or slightly cut on the under side, in order to prevent the bark from being torn in the fall; and when the branch has been removed, the edges of the wound, if anywise ragged, should be pared smooth with the knife. If the tree be vigorous, nature will soon cover the wound over with bark, without the addition of any plaster to exclude the air. In the shortening of a strong branch, the position of which is pretty upright, it should be observed to draw the saw obliquely across it, in such a manner as that the face of the wound shall be incapable of retaining moisture; and afterwards to smooth the edges of the bark with the knife." (Plant. Kat. 181.) In every case where
the branches are too large for the knife, Pontey prefers the saw, as the best and most expeditious instrument; and one, the use of which is more easily acquired by a laborer than that of either the bill or axe. In “large work” he uses the common carpenter’s saw; for smaller branches, one with somewhat finer teeth, with the plate of steel, and about twenty inches long. Having stated what is general in pruning, the next thing is to submit some particular applications of the art to resinous and non-resinous timber-trees, copse-woods, osier-holts, hedges, and hedge-rows, and trees in parks.

6892. **Resinous trees.** Pontey and Sang agree, should not be pruned at so early an age as the non-resinous kind. Sang commences about the sixth or eighth year, according to their strength or vigor, and removes no more than one or two tiers of branches at once. Pontey, when the plants are about eight feet high, gives the first pruning by “displacing two or at most three tiers of the lower branches; after which, intervening two years, this pruning might be repeated, and the improvement will be rapid; but except more shall prove good.” (Forest Pruner, 304.) Sang judiciously observes, “Excessive pruning, either of firs, larches, or deciduous trees of any sort, is highly injurious, not only to the health of the plant, but the perfection of the wood.” If a nutting man is instructed in the art of pruning a plant to produce abundance of leaves, perfectly to concord its juice, the timber will be loose in its texture, and liable to premature decay.” (Plant. Kal. 182.) The opinions of Nicol and Monteath are at variance with those of Pontey and Sang, as to pruning resinous trees. Nicol advises leaving snags (Pract. Plant. 213.), and Monteath (For. Guide, 45.) says, “Never cut off a branch till it has begun to rot, as the bleeding of a live branch will go far to kill the tree.”

6893. **Non-resinous trees.** Sang observes, that “should be pruned betimes, or rather from their infancy, and thenceforward at intervals of one or at most two years. If the pruning of young forest-trees is performed only at intervals of eight or ten years, the growth is unnecessarily thrown away, and wounds are inflicted which will ever after remain blemishes in the timber; whereas, if the superfluous, or competing branches had been removed annually, and before they attained a large size, the places from which they issued would have been imperceptible, or at least not hurtful to the timber, when it came to the hands of the artist. The pruning of all deciduous trees should be begun at the top, or at least those branches which are to be removed from thence should never be lost sight of. Having fixed upon what may be deemed the best shoot for a leader, or that by which the stem is most evidently to be elongated and enlarged, every other branch should be removed, or at least be reduced in size; but always observing to shorten at a lateral twig of considerable length. It is of importance that the tree be equally poised; and therefore if it have stronger branches on the one side than the other, they should either be removed or be shortened. Thus, a properly trained tree, under twenty feet in height, should appear light and spiral, from within a yard or two of the ground, the branches being more or less equal, and the shoot at the top forming, on either side of the tree, but two or three small branches, in order to obtain the sap, and circulate it more equally through the plant. Trees of this size, standing in a close plantation, after being properly formed, will require much less attention; indeed, such trees might as easily be dealt with by the ordinary farmer or ploughman as by the gardener; but if these keep well forty or fifty years, in their own places, their lateral branches will not be allowed to extend, but will remain as twigs upon the stem. These, however, frequently become dead branches; and if such were allowed to remain at all on the trees, they would in all likelihood produce blemishes calculated greatly to diminish the value of the timber: hence the impropriety of allowing any branch to die on the bole of a tree; indeed, all branches should be removed when they are alive; such a method, to our knowledge, being the only sure one to make good timber. From these circumstances, an annual pruning, or at least an annual examination, of all forests, is necessary.” (Plant. Kal. 180.)

6894. **Heading down such non-resinous trees as stule we have already (6829.) stated to be an important operation.** After the trees have been three or four years planted, Sang directs that such as have not begun to grow freely should be headed down to within three or four inches of the ground. The cut must be made with the pruning-knife in a sloping direction, with one effort. Great care should be taken not to bend over the tree in the act of cutting. By so bending, the root may be split, a thing which too often happens. The operation should be performed in March, and not at an earlier period of the season, because the wounded part might receive much injury from the severe weather in January and February, and the expected shoot be thereby prevented from rising so strong and vigorous. (Plant. Kalend. 297.) Buffon, in a memorial on the culture of woods, presented to the French government in 1742, says he has repeated this experiment so often, that he considers it as the most useful practice he knows in the culture of woods.

6895. **For the purpose of producing bents for ship-timber, various modes of pruning have been proposed.** According to Fonley, “little is hazarded by saying, that if plenty of long, clean, straight, free-grown trees could be obtained, a serrated form of the branches would greatly increase the value of the wood, experience, and in extensive practice, says, the value of the oak, the broad-leaved elm, and Spanish chestnut, depends a great deal on their being crooked, as they are all used in ship-building. He says he has seen oak trees properly trained to the desired shape, manner, “If you have an oak, an elm, or chestnut, that has two stems, as it were, striving for the superiority, Iop or prune off the straightest stem; and if a tree that is not likely to be of such value be standing on that side, to which the stem left seems to incline to a horizontal position, take away the tree, and thus give the other equal encouragement to incline horizontally, and in this time to have the natural circular shoots off the horizontal branch; and, indeed, if these branches, which is sometimes the case in these trees, seem to contend, take away most of them; but if they do not, it is better at this time not to prune these trees over-much, except the second shoots from the horizontal branch, till they are grown a little larger, for by this time it will be found that many of these branches are likely to form; and, if it inclines to grow crooked, lighten a little the top of the tree, by taking off a few of the crooked branches on the straighter side, allowing all the branches to remain on the side to which the tree inclines to crook, to give it more weight, and to draw most of the sap or juice that way, and it will naturally incline more to the crook; at the same time clearing away any other tree on the crooked side, that may be, with the wind, to whip the side of the tree to which it inclines to crook, also taking away such tree of less value as may prevent it from spreading out to the one side more than to the other.” He adds,
CULTURE, and others unless because the sides not gradually without much waste of wood, is nearly double in value to the same number of straight trees; and, indeed, knees of oak are extremely scarce, and difficult to be got."

"Pointed, ignorant of no way by which bends of tolerable scantlings (knees excepted) can be produced with certainty and little trouble, but from a side branch kept in a bent position by the branches of another tree or trees overhanging its stem." (Forest Pruner, 114.)

6897. Coppice-woods, in so far as grown for poles or bark, require pruning on the same principle as timber trees, in order to modify the ligneous matter into stem, and produce clean bark. In as far as they are grown for fence-wood, fuel, or besom-spray, no pruning is required.

6898. Oxter-halts only require the laterals to be pinched off the shoots intended for hoops; those for the basket-maker seldom produce any. The stools also require to be kept free from dead wood and stunted knotty protuberances.

6899. Hedge-rows require side pruning, or switching, from their first planting, so as gradually to mould them into "the wedge shape, tapering from bottom to top on both sides equally, till they meet in a point at the top. Two feet at bottom is a sufficient breadth for a five-feet hedge: a greater or a less height should have the bottom wider or narrower accordingly. In dressing young hedges, either of the deciduous or evergreen kinds, the sides only should be cut till the hedge arrive at the proposed height, unless it be necessary, for the sake of shelter, to cut their tops over, in order to make the hedge thicker of branches. Such cutting of the upright shoots, however, is not of any very great use in this respect; because every hawthorn-hedge sends out a number of side shoots, which, if encouraged, by keeping the top narrow as above, will make it abundantly thick." (Sang, 447.) In pruning hedges, some use shears; but the hedge-bill (fig. 115.) is the most proper instrument, and prunes a smooth unfractured section, not sept to cut out a number of small useless shoots as generally follow the bruised cut of the shears. (fig. 125.)

6900. Hedge-row trees require to be pruned to a tall, erect, clean stem, as at once producing more timber and doing least injury to the ground under their drip and shade.

6901. Trees in strips for shelter, or screens for concealment, ought to be furnished with branches from the bottom upwards; unless undergrowth supply this deficiency. Where this is not the case, care should be had that the trees be pruned into conical shapes, so as that the lower branches may be as little as possible excluded from the influence of the weather by the upper ones.

6902. Trees for shade, where shelter from winds is not wanting, should be pruned to ample spreading heads with naked stems; the stems should be of such a height that the sun's rays, at mid-day, in mid-summer, may not fall within some yards of the base of the trunk; thus leaving, under the tree, as well as on its shady side, a space for the repose of men or cattle.

6903. Trees in parks may be considered as chiefly ornamental; and for this purpose should be left with larger heads than such as are grown chiefly for timber. The height to which the stems are cleared of branches should vary according to the kind of tree (fig. 659. a to e); and hollies, thorns, and such shrubs as are left untouched, or that are protected by enclosure from the cropping of cattle (f, g), should be left entirely to themselves. In parks, where no pruning whatever is given to the timber-trees by man, we find they are all pruned or browsed to a certain height by cattle: this adds to their character as trees, but in flat surfaces forms a disagreeable repetition of the horizontal line in which they stand. To break this browsing line, pruning is a simple, obvious, and effectual resource.

6904. Some trees in pleasure-grounds and lawns, where no cattle ever come, may be allowed to extend their branches so as they may almost recline on the turf; others may be pruned to different heights, according to their kind. Linden, elms, elms, &c. have a fine effect with their branches depending from their trunks; and give an idea of seclusion and exclusive consecration to man, highly characteristic of what is called pleasure-ground.

6905. The properly thinning out of plantations, Sang observes, "is a matter of the first importance in their culture. However much attention be paid to the article of pruning, if the plantation be left too thick, it will be inevitably ruined." A circulation of air, neither too great nor too small, is essential to the welfare of the whole. This should not be wanting at any period of the growth of the plantation; but, in cases where it has been prevented by neglect, it should not be admitted all at once, or suddenly. Opening a plantation too much at once, is a sure way to destroy its health and vigor. In
thinning, the consideration which should in all cases predominate, is to cut for the good of the timber left, disregarding the value of the thinnings. For, if we have it in our choice to leave a good, and take away a bad plant, or kind, and if it be necessary that one of the two should fall, the only question should be, by leaving which of them shall we do most justice to the laudable intention of raising excellent and full-sized timber for the benefit of ourselves and of posterity? The worst tree should never be left, but with the view of filling up an accidental vacancy."

6906. In thinning mixed plantations, the removing of the nurses in the first object which generally claims attention. This, however, should be cautiously performed; otherwise the intention of nursing might be frustrated. If the nurses may be removed, it is essential that at least enough be retained, although the plantation itself be rather crowded, than where the situation is sheltered. In no case, however, should the nurses be suffered to overtop or whip the plants intended for a timber crop; and for this reason, in such situations, and when perhaps particular nurse-plants can hardly be spared, it may sometimes be necessary to prune off the branches from one side entirely. At subsequent thinnings, such pruned or disfigured plants are first to be removed; and then those which, from their situation, may best be dispensed with. At what period of the age of the plantation all the nurses are to be removed, cannot easily be determined; and, indeed, if the nurses chiefly consist of large trees, it may with propriety be said, that they should never be totally removed, while any of the other kinds remain. For, besides that this plant is admirably calculated to form part of a beautiful mixture, it is excelled by few kinds, perhaps by none, as a timber-tree.

6907. But when the nurses consist of inferior kinds, such as the mountain ash and the Scots pine, they should generally be all removed by the time that the plantation arrives at the height of fifteen or twenty feet, in order that the timber-trees may not, by their means, be drawn up too weak and slender. Before this period, it may not probably be necessary to prune them out; but, if the kind be such as the kind of the plantations of the Lustrous thriving plants, should first be condemned, provided their removal occasional no blank or chasm; but where this would happen, they should be allowed to stand till the next, or other subsequent revision. At what distance of time this revision should take place, cannot easily be determined; as the matter must very much depend upon the circumstances of health in which the plants may be. In general the third season after will be soon enough; and if the plantation be from thirty to forty years old, and in a thriving state, it will require to be revised again, in most cases, within seven years. But one invariable rule ought to prevail in all cases, and in all situations; to allow no plant to overtop or whip another. Respect should be had to the distance of the tops, not to the distance of the roots of the trees; for some kinds require much more head-room than others; and all trees do not rise perpendicular to their roots, even on the most level or sheltered ground.

6908. To the final prunings, to which trees standing in a mixed plantation should be thinned, it is hardly possible to prescribe fixed rules; circumstances of health, vigor, the spreading nature of the tree, and the like, must determine. Whether the trees are to be suffered to stand till full-grown, which of the kinds the soil seems best fitted for; whether the ground be flat or elevated; and whether the situation, in which the circumstances of health, soil, shelter, &c. are to be considered, are circumstances which must influence the determination of the ultimate distance at which the trees are to stand. It may, however, be said in general, that if trees be allowed a distance of from twenty-five to thirty feet, according to their kinds and manner of growth, they will have room enough to become larger timber.

6909. In the Scots pine, the stools of the plants have been put in at three or three and a half feet apart, will require little care until the trees be ten or twelve feet high. It is necessary to keep such plantations thick in the early stages of their growth, in order that the trees may tower the faster, and push fewer and weaker side branches. Indeed, a fir or soft wood plantation should be kept thicker at any period of its growth than any of those consisting of hard wood and nurses already mentioned; and it may sometimes be proper to prune up certain plants as nurses, as hinted at above for a mixed plantation. Those pruned up trees are of course to be reckoned temporary plants, and are afterwards to be removed; or to be kept up as such, which is a plan whereby all plantations of the condemned may be saved; because such will never regain them so far as afterwards to become stately timber; provided that the removal of these mutilated trees cause no material blank in the plantation. Care should be taken to prevent whipping; nor should the plantation be thinned much at any one time, lest havoc be made by the wind; for if nurse-trees are to be spared, this seems the more necessary, insomuch as Scots pine, intended for useful large timber, are presumed never to be planted except in exposed situations and thin soils. At forty years of age, a good medium distance may be about that; and so, that after a certain period, perhaps by the time that the plantation arrives at the age of fifty or sixty years, it will be proper to thin more freely, in order to harden the timber; and that, then, this may be done with less risk from the danger of, and less risk to the trees themselves, than by the method, however, of a general, and then gradually de-thinned, as they are able to keep pace with the new thinnings.

6910. Plantations of spruce and silver firs, intended for large useful timber, should be kept much in the manner above stated, both in their infancy and middle age. As already remarked, planting and keeping them as thick as is consistent with their health, is the best means of producing tall, straight, clean stems, and valuable timber. When planted for screens or for ornament, they require a different treatment; which will be noticed in the proper place.

6911. To larch-plantations, the above observations will also apply; and indeed they are applicable to all the kinds of roots, and to all trees, of which the stems, and the main or secondary branches of all young plantations should be kept thicker than the interior. The extent to which this rule should be carried, must be regulated according to the degree of exposure of the situation, the age of the plants, the tenderness of the kinds, and other circumstances.

6912. The proper seasons for thinning are autumn, or very early in spring, where the trees are to be taken up by the root and replanted elsewhere; and winter for thinning for timber and fuel; but such trees as are valuable for their bark should be left untouched till the sap rises in April or May. Copse-woods require thinning when young, like other plantations, and when once established the stools require to be gone over the second year after cutting, and all superfluous suckers and shoots removed. This operation should be repeated annually, or every two or three years. Connection with pruning, till five to four years of the general full of the crop.

6913. Ornamental plantations require to be thinned on principles agreeable to the intention with which they were planted. In the artificial forms, the figure must be carefully preserved, as the main object; and in plantations in imitation of nature, the principle of grouping and connection must be kept steadily in view. A thin part is to be rendered thinner, and a thick group, or constellation of plants not opened up, but merely deprived of such trees as are becoming smothered by the rest.
6914. Improving neglected plantations. Though it has been more or less fashionable, for upwards of a century, to form plantations; yet it has been also so generally the custom to neglect their future culture, that by far the greater proportion of the surface covered with trees in Britain may be considered as neglected or mismanaged. The artificial strips and masses have generally never been thinned or pruned; and the natural woods and copse-woods improperly thinned, or cut over. It is often a difficult matter to make much of such cases; and always a work of considerable time. "Trees," Sang observes, "however hardly their natures may be, which have been reared in a thick plantation, and consequently have been very much sheltered, have their natures so far changed, that if they be suddenly exposed to a circulation of air, which under different circumstances, would have been salubrious and useful to them, will become sickly and die. Hence the necessity of admitting the air to circulate freely among trees in a thick plantation, only gradually and with great caution. To prevent a misfortune of this kind, a plantation which has become close and crowded, having been neglected from the time of planting till perhaps its twentieth year, should have only some of the smallest and most unsightly plants removed: one perhaps, in every six or eight, in the first season; in the following season, a like number may be removed; and in two or three years after, it should be gone over again, and so on, till it be sufficiently thinned. It will be proper to commence the thinning, as above, at the interior of the plantation, leaving the skirts thicker till the last; indeed, the thinning of the skirts of such a plantation should be protracted to a great length of time." With thinning, pruning to a certain extent should also be carried on. "If the plantation," Sang observes, "consists of pines and firs; all the rotten stumps, decayed branches, and the like, must be cut off close by the bole. It will be needful, however, to be cautious not to inflict too many wounds upon the tree in one season; the removing of these, therefore, should be the work of two or three years, rather than endanger the health of the plantation. After the removal of these from the boles of the firs and larches, proceed every two or three years, but with a sparing hand, to displace one or perhaps two tiers of the lowermost live branches, as circumstances may direct; being careful to cut close by the trunk, as above noticed. In a plantation of hard wood, under the above circumstances, the trees left for the ultimate crop are not to be pruned so much at first as might otherwise be required; only one or two of their competing branches are to be taken away, and even these with caution. If it be judged too much for the first operation to remove them entirely, they may be shortened, to prevent the progress of the competition; and the remaining parts may be removed in the following season; at which time, as often observed, they must be cut close by the bole." (Plant. Kdl. 467.)

6915. The operation of thinning and pruning, thickening or filling up, or renewing portions that cannot be profitably recovered, should thus go on year after year, as appearances may direct, on the general principles of tree culture. And for this purpose the attentive observation and reflection of a judicious mind will be worth a year's plan, in which must be given with so much latitude. Fontey has noticed various errors in Kennedy's Treatise on Planting, and even in Sang's Kalendar, on the simple subject of distances, which have originated in their giving directions for anticipated cases, which had never come within the author's observation. "Most people," he says, "take it for granted, that if trees stand three feet apart, they have only to take out half, to make the distances six feet, though to do that, they must take down three times as many as they leave. By the same rule again, most people would suppose, that twelve feet distance was only the double of six; but the square of the latter is only thirty-six, and that of the former an hundred and forty-four, or four times the latter; so that to bring six feet distances to twelve, three trees must be removed for every one left." (Profitable Planter, 256; Forest Pruner, 21.)

6916. Copse-woods are sometimes improved by turning them into woods, which requires nothing more than a judicious selection and reservation of those shoots from the stools which are strongest, and which spring more immediately from the collar. But a greater improvement of copse-woods consists in cutting over the overgrown and protuberant stools, by the surface of the soil (fig. 660, a, b, c, d), which has been found by Monteath completely to regenerate them. The operation is performed with a saw, in a slanting direction, which is the common way of keeping young shoots being afterwards properly thinned and pruned, soon establish themselves securely on the circumference of large, and perhaps, rotten-hearted roots. (Forester's Guide, 60.)

6917. Hedge-rows are often neglected, and, like larger plantations, require renovation by cutting down and filling in at vacancies, and by cultivating the soil at their roots. Hedges, Sang observes, which have been long neglected, shoot up to a great height like trees, become naked at bottom, and occupy too much ground, at least for lands in a state of high cultivation. The best method of reducing such to a proper size, and of forming them into an immediate fence, is by plashing.

6918. Plashing. This consists in selecting the strongest and straightest shoots. These are to be dressed up and headed down to four feet, and in such a way that the tops of the whole may range in a neat line. These are called the stakes; and, when they are deficient, either in strength or number, recourse must be had to artificial stakes, which must be driven in to stand firm, and supply the deficiency of natural ones. Having proceeded thus far in preparing the hedge for plashing, the hedger is to begin
at one end, and bend down as close as possible the remaining pliable branches, crossing them in the manner of basket-work. Such as are too strong to be bent, may be cut half through with the bill, which will render them pliable enough to be used; and such as are not required for any of the above-mentioned purposes, must be cut off close to the ground. After the plashing is finished, the hedge should be dressed smooth on both sides by the switching-bill or shears. There is another method of plashing, which has been suggested as an improvement upon the foregoing; and that is, by not cutting any of the stems over as stakes, but weaving in the tops along with the other branches. This method will not have so immediate a tendency to bare the lower parts of the hedge by the growth of the top, as when any of the plants are cut over for stakes; but still, at the bendings, the growth will rush out with vigor; besides this plan is attended with more labor. Indeed, the best security against boring the bottom of a plashed hedge, is by cutting over by the surface as many of the plants as can be at all spared; and the shoots arising from these will soon thicken the hedge at bottom. Plashing can only be effectually and handsomely performed, when there is a good portion of long, pliable, and well feathered branches, and where the hedge has, if not youth, at least vigor, on its side. After the plashing is completed, the ditch is to be scoured out, and the bottom of the hedge cleaned and dressed up, in the same neat manner as if all were new work.

6949. Cutting over old hedges is a much less expensive method of reclaiming or renewing, than any of the above; and, perhaps, in most cases, may be a more eligible one; saving when an immediate fence is the object. In cutting down an old hedge, there is certainly a very fit opportunity of laying the foundation of a complete and durable fence. The nature of the cutting must be regulated by circumstances, according to the age, the strength, or the closeness of the hedge, and whether it have been planted in single or double rows. If the hedge in question be pretty vigorous and branching towards the bottom, and if the stems be cut down closely together, it may be brought into due subjection, without being cut down to the ground. In this case, the sides are first to be switched up with the hook, not altogether close to the stems, but within about a foot of them on each side at bottom, which should be four or five feet high, according to the general height of the hedge: but if the hedge be thin at bottom, it will be advisable to cut more in, in order to make it bushy from the ground upwards. If the hedge is not regularly close from end to end, but ragged, and full of gaps, the best method is to cut it over, within eight or ten inches of the ground, and to fill up the gaps with stout well-rooted plants of the same kind; or the gaps may be mended by the following method: — Let one of the stoutest thorn-plants next to the gap be reserved uncut, and the space be digged over, or it may require to be filled up with rich earth to within three inches of the height of the top of the ditch. Then having cleaned the thorn-plant of all side branches or twigs, cut it half through at the height of the earth in the gap, on the side farthest from it, and lay it down upon the earth, securing the most distant end from rising up by a hooked pin; then cover it all over with rich earth, so as to make it the general height of the top of the ditch: and the thorn-plant so laid down and covered, will take root, and send up a profusion of shoots over its whole length. If one plant will not reach the whole extent of the gap, one at each side probably will. The surface of the bank should be cut out, and the ditch scoured as above directed in plashing.

6950. In other cases, when the hedge is getting thin below or too tall, and when the stems are placed regularly within eight or ten inches of one another, and where it is necessary to retain a fence and at the same time to cut so as to have a supply of young shoots from the bottom, the plan to be followed is to cut away the bottom portion up to within eight or ten inches of the bottom, and the other at four feet high, dressing the bank and scouring the ditch, as directed above. In cases where two rows of quicks have been planted, the front one is to be cut by the surface, and the other at four or five feet high, as circumstances may require.

6921. Neglected hedge-row timber may be improved by pruning according to its age. Blayke recommends what he calls foreshortening, or cutting in, as the best method both for young and old hedge-row timber. "This operation is performed by shortening the over-luxuriant side branches (fig. 661. a), but not to cut them to a stump, as in snag pruning; on the contrary, the top only of the branch should be cut off; and the amputation effected immediately above where an auxiliary side shoot springs from the branch on which the operation is to be performed (b); this may be at the distance of two, four, or any other number of feet from the stem of the tree; and suppose the auxiliary branch which is left (when the top of the branch is cut off) is also over-luxuriant, or looks unsightly, it should also be shortened at its sub-auxiliary branch, in the same manner as before described. The branches of trees pruned in this manner are always kept within due bounds; they do not extend over the adjoining land to the injury of the occupier, at least, not until the stem of the tree rises to a height out of the reach of pruning, when the top branches can do comparatively little injury to the land. By adopting this system of pruning, the bad effects of close pruning on old trees, and snag pruning on young ones, will be avoided; the country will be ornamented; and the community at large, as well as individuals, benefited."
6922. Hedge-rows frequently require to be altered in direction to improve the form, or increase the contents of farm-enclosures. (fig. 662.) Generally, and especially in
662
flat arable lands, this is done by eradicating such as are in unsuitable directions (a), and substituting others (b) in parallel, or at least in straight lines; but in rising grounds, and where the surface will be improved by shelter, it frequently happens that a crooked hedge is superseded by two straight ones, and the interval (c) filled up with plantation. The advantage of straight-lined fields to a farmer is very considerable; and when this object is procured in the latter way, an improvement is produced both useful and ornamental.

6923. Ornamental plantations are no less frequently neglected than such as are considered chiefly useful. Clumps, belts, and screens which have become thin, because they have not been thinned, are almost everywhere to be met with. "In those neglected plantations," says Lord Meadowbank, "where daylight may be seen for miles, through naked stems, chilled and contracted by the cold, the mischief might, perhaps, be partially remedied, by planting young trees round the extremities, which having room to spread luxuriantly, would exclude the wind, and the internal spaces might be thickened up with oak, silver firs, beeches, and such other trees as thrive with a small portion of light. When once the wind is excluded, the weakest of the old trees might be taken out, and the others left to profit by the shelter and space that is afforded." (Life of Lord Kames, by Tyler.) One of the most hopeless cases of improvement in this department is that of an old clump of Scotch pines (fig. 663), from which scarcely any trees can be taken without risking the failure of the remainder. The only way is to add to it, either by some scattered groups in one direction, or in various directions. Where a clump consists of hard wood, either entirely or in part, it may sometimes, if effect permits, be reduced to a group, by gradually reducing the number of the trees. The group left should be composed of two or three trees of at least two species, different in bulk, and some what in habit, in order that the combined mass may not have the formality of the clump.

6924. Scattered trees in ornamental scenery otherwise of very good shapes, and very well managed as to pruning, destroying the browsing line, &c. individually, are often, from want of thinning in some places, and thickening in others, deficient in massiness

(fig. 664.); the obvious remedy is to thin out some (a), and plant others, so as to destroy the straggling non-cooperating appearance which such trees present, and produce something of grouping, massiveness, and character. (fig. 665.)

6925. Wounds, bruises, casualties, and defects of trees. Small wounds, such as are required to be made by judicious pruning, easily heal up of themselves; large wounds, by amputations of branches, above six inches' diameter, should, if possible, never be made. Even wounds of six inches' diameter, or under, will heal quicker by the application of any material which excludes the air and preserves the wood from corruption; and we agree with Sang, in recommending coal-tar, or the liquor produced from coals
in manufacturing gas. It is, however, less favorable to the progress of the bark over the wound than a coating of clay or cow-dung, covered with moss to keep it moist. Pontey recommends putty and two coats of paint over it. In case the wood, at a bruised or amputated place, have by neglect become already corrupted, the rotten or dead wood is to be pared out quite into the quick; and the wound is then to be dressed with tar, or clay covered with a piece of mat, sacking, or moss. A wound, hollowed out as above, may at first appear an unsightly blemish; but, in subsequent years, nature will lay the coats of wood, under the new-formed bark, thicker at that place; and probably may, in time, fill it up to be even with the general surface of the tree.

6926. All fractures, by whatever means produced, are to be managed as the circumstances of the case require. If a large branch be broken over at the middle of its length, it should be sawn clear off close by the lateral which is nearest to the bole of the tree; but, if there is no lateral, or branch, capable to carry forward the main or fractured branch in quito to the bole. In both cases, treat the wounds as above recommended.

6927. Interior rotting, arising from the dampness of the soil, cannot by the art of man be cured; though it might have been prevented by timely draining. The hearts of trees frequently rot, where there is excess of moisture, and especially such as have been produced from old hedges; and it is a previous felling. Such roots, when in good ground, send up very great shoots with few leaves in proportion to their sizes; by the absence of a profusion of these, properly to concoct the juices so abundantly supplied by the roots, the fibre of the wood is loose and imperfect; the next season will supply more leaves in proportion to the supply of juices, yet not a sufficient number for making perfect timber; several years may pass before this event arrive; thus crude and ill digested timber disposed to premature decay, is the foundation over which subsequent coatings of wood are laid: yet, however perfect these may be, they do not prevent the decay in the substance, for the innermost leaves are to the proportion of the solid wood; the cotyledons and subsequent leaves of a one-year-old tree are a thousand times greater, compared to its solid contents, than are the leaves to the solid contents of the first year’s shoots from roots like the above.

6928. Shades from the weight and multiplicity of top branches, and might have been prevented by timely pruning. Shakes or rents in the boles of trees, however, often happen where there is no excess of tops. Sometimes the rain running down from the branches, wets one part of the bole, while the rest is comparatively dry. If this circumstance is succeeded by an intense frost, before the wetted side becomes dry, the bole may be rent for a great length, and perhaps to the depth of the core. Shakes or rents, like the above, are difficult to cure. The best method of helping them, is to trace out their upper extremity, caulk it up with oakum, and pitch it over, to prevent the rain descending that way in future. (Song)

6929. In cases of hollowness, Pontey recommends probing to the bottom, letting out the water, if any, with an auger, drying the cavity with a cloth, filling it with dry sand, plugging it with wood and oakum, and then painting it over.

6930. Distracted trees or branches by lightening, or otherwise, if the soft wood is not much injured, will heal over and become covered with bark; and this the more certainly and rapidly if the air be excluded by a coating of adhesive matter, as cow-dung and quick-lime, or tying on moss or bandages of mat or cloth. Pontey gives an instance in which such treatment was successful in the case of an apple-tree. He has witnessed it as an extensive scale on the trunk of a pear-tree; and we are informed, on the best authority, of other cases now under progress, in the government garden of the Luxembourg at Paris, as matter of experiment, by Du Thure, a most ingenious physiologist. If stumps are left, from improper pruning, or the want of it. We often see it from improper pruning of elms, which, after having been close pruned to their summits for many years, are left entirely to nature; in that case they branch out luxuriantly below, and the top withers. By neglecting to thin out the branches on the stems of other trees, the same effects were produced.

6932. Stinted bushy tops show a deficiency of nourishment; on very tall naked stems it is from these circumstances; and on short stems from defects in the soil. Obliquely placed misconap heads, in detached trees, commonly proceed from the same causes and want of shelter. Stinted growth, both in tops and stems, is also produced by ivy, and by lichens, mosses, the mistletoe, and other parasites. Ivy compresses the bark, precludes its expansion, as well as excludes air and moisture, by which the outer bark becomes rigid and corky. Happily, both men and trees will live a long time under the influence both of deformity and disease.

6933. Excessive exudations of gum and resins are peculiar to resinous and some other trees when over-pruned, or pruned at improper times. Mildew, honeydew, and blight, three popular names applied to the effects of certain insects of the aphid kind, attack the oak, beech, poplar, and many trees; all that can be said is, if proper regimen has been regularly attended to, trees will overcome these and all other enemies.

6934. Insects and vermin. Almost every tree has its particular insect of the hemipterous and dipterous families, and many of the coleoptera family are common to all. The foliage of the small-leaved elm of hedges is often almost entirely destroyed in the early part of the season by teenthrednites; and those of the larch and Scotch pine have suffered materially in some seasons from aphides. The Aphils taricca, L. (Eriosoma of Leach) increased to an alarming extent from 1800 to 1802, on the larch, on account of the excessive growth of new matter, following each other; but, though it retarded their growth, it ultimately destroyed the very few trees. Sang says he has known it since 1753; that it ditties more than injures the tree, and is now (1819) thought little of. Indeed, almost every species of tree has been known to have suffered in one or some seasons, and in particular districts from insects, for which, on so large a scale, there seems little operator remedy but cautiously waiting till their excess, or the force of a few vermin, their natural enemies, or a change of seasons, cause them to disappear. Trees, properly cultivated and managed, generally overcome such enemies. The hane is well known to be very injurious to young trees, and especially to laburnum, by gnawing off their bark. Coating their stems with dung and urine, fresh from the cow, or with a thin mixture of a water of half the size of a small remedy, and mixed with a brush about two feet high; a barrow-load will suffice for a hundred trees, with stems of three or four inches in diameter; and its virtue, after laid on, endures at least two years. (Bull, in Caled. Hort. Mem. iv. 190.)
of the different products afforded by trees, the first is their leaves, which are or may be collected in close plantations for the sake of the manure they afford; and in open groves, parks, and lawns, for that purpose, and to prevent their injurious the grassy surface. Leaves are also gathered on the continent as food for cattle. Though, at first consideration, leaves would appear to benefit pastures by sheltering the roots of the grass during winter, and afterwards rotting into manure; yet experience proves, that in considerable quantities they impede the growth of the grass plants, by bringing on decay at their roots, in all probability owing to their exclusion of air. For this purpose, in well wooded parks, the leaves are carefully collected in the beginning of winter, and carried to rot-heaps in secluded situations, where in two years from the time of gathering, they become the valuable mould so much in demand by the gardener. A very ingenious machine for sweeping together, and at the same time lifting up leaves into a box or receiver, has been invented by Snowdon, a London machinist, and has been partially in use in Windsor Forest and at Hampton Court; it is also calculated for cutting or wrenching off weeds, (as clean cut weeds are found to grow again, the same season, while the roots of the others often rot,) or mowing and lifting the weeds or swath into the cart; but it is not yet sufficiently matured to enable us to describe it as completely answering all its intended purposes. Great credit, however, is due to the ingenious inventor, who has been occupied on it for upwards of two years, and who has spared neither time nor money.

6936. Prunings or spray are the next product of trees; those which they afford at a very early period, and all clippings of hedges or artificial forms, are only fit to be used as leaves; the larger prunings may be used for some of the various purposes to which coppice-wood and the top of trees are applied. On the contrary, the growth of any of all kinds is carefully gathered in summer, dried and sacked for the use of cattle in winter. This was also the practice of the Romans, who preferred the sprays of the elm, as the Swedes do that of the birch.

6937. The thinning, when not beyond a suitable age, and taken up properly (6905.) and at a proper season, may be replaced by single trees and groups, or they may be used as hop-poles, poles for garden-training, for fencing, for props in coeliers, and for a great variety of purposes; those whose barks are useful for tannin should not be cut down or rooted up till May, but the others at any time during winter. It is common to sort them into lots, according to their kind or size; and to taggot up the spray for fuel, besom-stuff, or for distilling for bleachers' liquid. See Coppice-woods. (6940.)

6938. The seeds of trees in general cannot be considered of much use beyond that of continuing the species, and therefore, in very particular cases when it is desired a tree should attain bulk as rapidly as possible, the flowers should be pinched off as they appear. The seeds of the oak, beech, and sweet chestnut, however, are valuable for feeding swine, and where they abound may either be swept together after they drop, and carried away and preserved dry in lots for that purpose; or if other circumstances are favorable, swine may be driven under the trees to collect them. These, and other seeds, as the haw and holly, are also eaten by deer. The seeds of the trees mentioned, and of all the resinous tribe, are in general demand by the nurserymen for the purposes of propagation. The seeds of almost all other trees and shrubs are also in limited or occasional demand; or may be collected for private sowing. They generally ripen late in the season, and are to be collected in the autumn or beginning of winter, with the exception of a few, such as the elm, poplar, willow, and one or two others, which ripen their seeds in May or June.

6939. In swarthgrounds, willows, whether intended for the basket-maker or cooper, should not be cut till the second growth after planting, in order to strengthen the stools; but by the third autumn the crop will be fit for the basket-maker, and the fourth, plantations intended for the cooper (hoops requiring the growth of two years) will be ready. The seasons for cutting are November and March; after the former period, the wood is in utmost perfection, and is fit for the same purpose, but is lost by bleeding, and the buds are developed too suddenly to admit of proper strength in the shoots. The cut should be made within three buds of the point whence the shoot issued, in a sloping direction, and the section on the under-side. (1885.) In cutting hoop-willows, the swell at the bottom of the shoot should be left, that being furnished with abundance of buds for future growth. After being cut, the hoops are trimmed from any side shoots, and tied up in bundles of a hundred, of six scores each, which, in 1820, sold on from four shillings to five shillings a bundle. The willows are sorted into three sizes, and tied in bundles two feet in circumference, within a foot of the lower ends. When to be peeled, they are immediately set on their thick ends in standing water, a few inches deep, and there remain until the growth ascends freely, which is commonly by the end of the succeeding May. “The apparatus for peeling is simply two round rods of iron, nearly half an inch thick, sixteen inches long, and tapered off towards each other at the one end which is sharpened, so as that it may be easily thrust down into the ground. When thus placed in a piece of firm ground, the peeler sits down opposite to it, and takes the willow in the right hand by the small end, and puts a foot or more of the great end into the instrument, the prongs of which presses together with the left hand, and with the right draws the bark from the willow. The stick will at the same time be separated from the wood at the end is then treated in the same manner, and the peeling is completed. Good willows peeled in the above manner, have been sold for some seasons past, at from six shillings and sixpence to seven shillings the bundle of four feet in circumference. After being peeled, they will keep in good condition for a long time, till a proper market be found.”

6940. Coppice-woods are generally cut over when the shoots of the stools have attained from three to five inches diameter at their bases; some grown chiefly for hop-poles, and ware or stuff for cranes, hampers, or hoops, are first gathered when the leaves fall, where for fencing, or for whatever purposes is wanted, are left later. In some parts of Herefordshire, where the oak grows with great rapidity, coppice-woods are cut over every twelve years; in the highlands of Scotland, where it grows much slower, the time varies from twenty to twenty-five or thirty years. “The bark is there considered as having its greatest value, at its highest value, at the age of between twenty and thirty years: under that age, its virtues are weak; above it, the bark becomes coarse and loses its sap. Another important reason for cutting down oak coppe-coop wood about the above period, is suggested in the Stirling-
sire Report, p. 218; namely, "that it is a fact established by experience, that it will not renew itself, if it remains uncut, beyond the space of about forty years." (Gen. Rep. of Scotland, 218.) Where the most marked tract of country is subject to the influence of a dry climate, it is in practice to fall back to the period of cutting. These are to be cut in rotation, so that when the last portion is cut over, the first is again ready for cutting.

693. Of the proper time for cutting the kinds of trees whose barks are not made use of, is winter and early in spring; but the oak and other trees which are peeled, are left till the middle of April or May. Birch and larch woods will be ready nearly a month earlier than the oak. Should there be no frost, birch and larch may be peeled about the beginning of April; but the birch is commonly allowed to stand till July, and larch may be cut in the middle of May. It is observed that of the common oaks, when the sap begins to rise, an outer skin upon birch-bark which requires to be taken off, as it is of no use to the tanner, and renders that part that is of use more difficult to be ground, and the month of July is the only time at which the two barks can be separated with ease, as at this time the juice or sap has made its circulation through the wood. The barks are, consequently, rendered more valuable than if they were cut off in May to the middle of July is the usual time for barking the oak. The earlier in the spring this operation is performed on the oak, both for the growth, if a natural wood, and for the bark, the better. When the sap enters the tree the bark will easily be taken off without loss of time; and if the whole could be taken off before the leaf is completely developed, the bark would be better. After the sap has arisen to the leaf and new growth, the bark becomes more dry, and requires more beating to separate it from the wood. And when what is called the black sap, or sap, as it is called, is off, the bark, if originally taken off, would be better. The bark begins to throw off a scurf, more especially young bark without much cork on it; this outer skin having less of the proper sap or juice, and being much drier when taken off, will weigh less, and consequently will not be so valuable. If possible, oaks should be barked by the middle of June, as every ton of bark taken off after the first of July will be deficient two cwt. per ton, compared with the same quantity taken off in May or early in June.

694. The termination of cutting is generally fixed for the fifteenth day of July, and after this date there should be no cutting. About this date the cutting of the birch is generally commenced, because, at that time, the fifteenth, the whole of the wood and bark should be carried away, that the young growths may not be disturbed or injured, as at this time they will have made considerable progress; at any rate, there should neither be wood nor bark remaining within the new cut hag after the first of August; nor should either be removed or permitted to lie for a single day after the cutting is discontinued. It is observable, that this makes what is termed a lammas growth, and the future prosperity and health of the coppice, in a great measure, depend on the first year's growth, as far as regards form and vigor of the shoots. (Forester's Guide, p. 69.)

695. The best mode of cutting is evidently that of using a saw, and cutting the shoots over in a slanting direction close by the surface. When the stool, after having been cut several times, has acquired considerable diameter, it is customary in the midland counties, Marshall states, to hollow it out in the centre, from the top to the bottom, and remove the outer or coping root, the smaller roots, and every bit of the stump, thereby making it easy, and come as it were separate plants. This is in fact the case in very old copses. For several cuttings, however, it must evidently be the safer policy to keep the stool highest in the middle to throw off the rain, and preserve it sound. 696. He says, "It will be found, upon experiment, perfectly evident, that stools dressed down to the surface of the ground, (taking always not to loosen the bark from the root, or allow it to be peeled off in the smallest degree below the earth, but round down level to it,) that these stools will send forth the most vigorous shoots, and stand the weather, and be the stoutest and best throughout the age of the coppice. The stools of the late season, if cut through the side, or if cut short of the root, are always cut, they often receive considerable injury, both from that circumstance, and the manner in which the operation is performed. Monteath appears to us to have furnished the best directions for executing the work in a safe manner. He first turns the person furnished with an instrument with a sharp cutting-edge (fig. 110.) through the cope, whose business is "to trample down the long grass or foggage all round the root, and then, to make a circular incision into the bark so deep as to reach the wood, at about an inch above the surface of the earth; thus the bark when taken off, will injure no part of that which is below, in its subsequent growth." 697. The root of the tree being thus prepared, the cutters ought to proceed to their part of the work, not with an axe, however, as is most generally recommended, but with a saw, because, in cutting with the axe unless the root of the tree be so small in diameter as to be severed in one or two strokes at most, it is impossible for the roots to be severable, that is, cut so as to that root to fall or fall altogether to grow. Therefore if the diameter of the root be six inches, or upwards, it should always be cut with a cross-cut saw; entering the saw about half an inch above where the circular incision has been made; if a small root, but if the tree be ten or twelve, or more inches in diameter, the saw ought to be entered two inches above it. 698. There are two advantages to be derived from cutting with the saw; it has no tendency to loosen the root of the tree, but leaves it in such a condition as to be more easily and properly dressed; it also saves a portion of the wood that would otherwise be destroyed by the axe. On no pretence should oaks of six inches' diameter be cut with an axe, but always with a saw. Having cut through the tree with a saw, take a sharp adze, and round the edges of the stool or root, going close down to the surface of the earth, taking with the adze both bark and wood, sloping it up towards the centre of the stool, taking particular care always that the bark and wood both slope alike, as if they formed one solid body, being sure always that the bark be not detached from the root. An objection has been made to this mode of cutting with the saw, as taking up too much time; but I have found that two men with a cross-cut saw, will cut one sapling in two men with an axe. (Forester's Guide, p. 65.)

699. The disbarred timber is prepared for sale by being sorted into straight poles of the largest size, and other pieces fit for palings, faggots, fuel, &c. The unbarred wood is similarly sorted, and affords, where there is much hazel or ash, cord-wood or bundles of clean shoots for making packing crates, hammer, and other kind of small furniture. In exceptionally fine woods, it is used for distilling the pyrexyous acid, used in blush-bleches and calico print-works. 700. When wood of this description is cut, the cutters sort it, and, as much as possible, into lengths which, if the purpose of distilling it, it sells readily at from 1s. 2d. to 1s. 10d. per ton; but when there are large cuttings, particularly of young woods, it is worth more to erect boilers near the wood to distil it, as these boil it down to a very great degree, and in the low countries, as it is consumed, at less expense than the rough timber could be; of course it will pay much better. Small wood of this description is also used for charcoal; but in distilling it, there is part of it made into charcoal, which will supply the demand of that article, so that it is by far the most profitable way, when there is a large quantity, to erect distilleries near the wood. Directly the wood begins to dry, the wood will admit of its being shipped at a small expense, and carried to where the works mentioned are carried on. All kinds of wood will give the extract in question, excepting fir; but oak, ash, Spanish chestnut, and birch, are the best. (Forester's Guide, p. 155.) Where the oak grows slow, as in the higher lands, the but-ends of the poles are used for spokes for chaise-wheels. "Long spokes are from thirty to thirty-two inches by three inches and a half broad, and one inch and a half thick, and the short ones for the same purpose, from twenty-two to twenty-four inches long, and the same size otherwise. Cart.
wheel spokes, from twenty-six to twenty-eight inches long, four inches broad by two inches thick. These are the sizes they require to stand when rough-blocked from the axe. Small wood when sold for building purposes is measured by cubic inches, and not feet.

6948. In some cases cope-woods are sown with grass-seeds, and pastured by sheep, horses, and cattle. Some admit the animals the fifth year after the last cutting, others not till the eighth; but Montaeath thinks the latter would never of the value, which by its year. If the farming is put by the stock, the nature of the soil, it can seldom be advantageous to admit any species of stock unless during a month or two in winter.

6949. In the operation of barking trees, "the barkers are each furnished with light short-handled mallets, made of hard wood, about eight or nine inches long, three inches square at the face, and the other end sharpened like a wedge, in order the more easily to make an incision in the bark, which is done all along the side of the tree which happens to be uppermost, in a straight line: and as two barkers are generally employed at one tree, it is proper, that whilst the one is employed in making an incision with the mallet, as above, the other being furnished with the barking-awl (fig. 140.), cuts the bark across the tree, in lengths of from two feet six inches to three feet. Having thus made the incision in the bark, both ways, the barkers being also each furnished with peeling-irons (figs. 136. to 139.), if the tree or piece of timber to be barked is such as the two barkers can easily lift one end of it, this is placed on two pieces of wood, three feet long, and called horses; these are about the thickness of a paling-stake, and have a forked end on each about six inches long, the other end sharpened to go into the ground; two of these horses are placed in a triangular form against one another, one end of the piece to be peeled being raised on the horses, the two barkers standing opposite to each other, and entering the peeling-irons into the incision made by the mallet, and pressing the iron downwards between the bark and the timber. In this way it will be found very easy to take the bark off in one whole piece round the tree; and, if possible, let these pieces be as long as the incisions made in the bark. In some cases, where there is not much sap, the bark may require a little beating with the square end of the mallet, to cause it to separate easily from the wood; but the less beating with the mallet the better, as it has a tendency to blacken the bark in the inside, or fleshy part of it, so that when the tanner sees it, he supposes it to be damaged, and undervalues it. The branches of the tree being previously all lopped off with the axe, the persons, in number according to the extent of the work, with the bill smooth all the branches, cutting them in lengths of from two feet six inches to three feet, down as small as one inch in circumference. The barkers, principally women, are each provided with a smooth hard stone of about six or eight pounds weight, beside which they sit down, and having collected a quantity of saplings, branches, or twigs, they hold it on the stone with one hand, and with the mallet in the other, they beat the piece till the bark be split from the wood, from the one end to the other, and taking it off all the length of the piece, if possible, then lay it regularly aside, till a bundle of considerable size is formed."

6950. Drying the bark. "The point most particularly to be observed in this art is, putting the bark up to dry; which is done by putting the bark upon what is called the lofts or ranges. These are erected by taking forked pieces of the loppings, called boughs, one the other three or four feet long, and four inches thick, with bark on one end, and four inches thick, with bark on both ends, twelve to seventeen inches thick, laid across the ranges. It must be kept up in an airy dry situation, in a high range, to admit of air passing through it. After it has lain in this state for three days, if the weather is dry and warm, the bark must be removed, and the small barks spread out, so as to allow it to sit together, which, if much pressed, is apt to do; and if it does so with the natural sap in it, it has a chance of moulding, which is extremely hurtful to the bark, and both lessens its weight and value. After the bark has stood on the ranges about eight or ten days, if the weather be good, it may either be put into a house or shed, or if intended to be put up into a stack, it may now be done. A stack of bark ought to be made in three or four courses, each one from eight to fifteen feet high, the boughs of the lower course being placed lower down, and those of the course above raised in the middle like a haystack. If it is to stand any length of time in the stack, it ought to be thatched, and in that state may remain all winter. The greatest care ought to be taken to preserve the color of the inner parts of the bark, because the color of it is generally looked to as a principal criterion of its value, and the merchant will pay a particular attention to it. Before it is sent into the compound or stocked, it ought to be dried out of it, in order to prevent its fermenting; because if a fermentation takes place in one part of the stack, it generally goes through and spoils the whole. The same mode of treatment will do for all kinds of bark as well as the oak; but the birch has an outer or shrilly skin upon it, that is of no use, and rejected by the tanner, and, as already observed, must be peeled off.

6951. Chopping the bark. "When the bark is ready for the tanner, it has to undergo the work of chopping, which is done by driving in two or more stakes into the ground, with a fork on the upper end of each stake; the space between the ground and the fork of the wood across between the two, where a number of people stand, and the bark is carried and laid down between the stakes, which, as any part of the bark is made to be cut up, they take up in their hands and lay on the cross-tree, and then, with a sharp whittle or bill in the other hand, they cut it into small pieces, about three inches in length; when this is done, it is trampled in bags, which hold about two hundred weight each bag, in weight. It is weighed with the bale, the tons, hundred weights, quarters, and pounds, and in the average manner delivered to the merchant or tanner."

6952. Pollard-trees, which may be considered in most cases as injurious deformities, are lopped at stated periods like cope-woods, and the top, whether to be barked or otherwise, is to be treated in all respects like that of copse.

6953. The period at which trees are felled, for the sake of their timber, is determined by various causes. By maturity of growth, or where the annual increase is so trifling as..."
to render their standing no longer worth while in point of profit: when wanted for private use or sale; or when defects in the tree, or new arrangements, in its situation, point out the necessity of its removal. "A timbered estate," Marshall observes, "should frequently be gone over by some person of judgment; who, let the price and demand for timber be what they may, ought to mark every tree which wears the appearance of decay. If the demand be brisk and the price high, he ought to go two steps farther, and mark not only such as are full-grown, but such also as are near perfection." In trees, as in the human species, there are three stages, youth, manhood, and old age. In the period of youth, the growth is rapid; in manhood, that growth is matured; and in old age, it begins to decay.

6954. The most profitable season for felling timber is at what may thus be termed the beginning of manhood. After that time, though the tree may appear sound and healthy, its annual increase is so little, that it would be more profitable to cut it down and replant. The number of years that a tree may stand, before it begins to lose its value, may vary somewhat, but the difference, so considerable, will be ascertained—by the annual shoots—of the state of the bark—and by taking the circumference of the tree at the same place for two or three successive seasons, and comparing the difference. In the view of profiting from timber produce, it is of great consequence to cut down plantations at maturity. Many trees will stand half others a whole century, after they are full-grown, appear quite healthy, and, at the same time, make little or no increase of timber. But there are particular cases, arising from the nature and state of the markets, where it may even be more profitable to cut timber before it is arrived at a full growth. (Treat. on Countr. Res. i. 577.)

6955. Preparations for felling. It has been strongly recommended to disabuse trees a year or more before they are taken down in consequence of the result of certain experiments commenced by Buffon in 1737. In May of that year, he disabused three oak-trees, forty feet in height, where they stood. In the course of three years, they lived, and were cut down, the outer wood being found hard and dry, and the inner wood weak and softer. After trying its strength, &c. he concludes, that "timber which has been disabused and dried while standing, will weigh heavier, and prove stronger than timber cut in its bark." Bosc, and other French authors, (in Cours Compl. d' Agric. &c. art. Aubier, Boly, Guercus, &c.) strongly recommend this practice, which is followed in some places on the continent, and in this country with the oak and larch; but not, as far as we have learned, with any other tree. Montefelt finds it by far the most efficient way of seasoning larch-timber. He barked some trees in spring, and did not cut them down till autumn, and others stood in the peeled state for two years. After various and extensive trials, he is decidedly of opinion, that the larch treated in this way at thirty years of age will be found equally durable with a tree cut down at the age of fifty years, and treated in the ordinary way." (Forester's Guide, 122.)

6956. As the dry rot (Merulius destruens, Saw.) is found to arise in a great measure from want of seasoning, or at least to proceed with the greatest rapidity in timber not well seasoned, this practice seems to deserve adoption in that point of view. (Encyc. Brit. Suppl. art. Dry Rot.) In some parts of the north of Europe, the trees are divested of their bark for one or two feet in height from the ground a year or more previous to their being cut down, which they afterwards stand. Like the larch, by the time we made diligent enquiry in Sweden, we could not learn distinctly the extent to which it was practised in that country and Norway. It is occasionally practised in both for the ostensible purpose of hardening the soft wood; but also accompanied by a deep incision made for the purpose of extracting tar; a practice obviously injurious to the timber, and therefore generally in these countries kept out of view. When trees stand close together, a very obvious preparation to felling is lightening the tops of such branches as would do injury in falling to the trees that are to be left, or to other adjoining objects.

6957. The season of felling is commonly winter, for timber not to be disabused; but some for the resinous tribe recommend summer as being the season in which it is generally felled in the north of Europe and in the Alps. But the summer season is there adopted from necessity, as in winter the woods are so filled up with snow that felling is hardly practicable. As the timber of these countries is generally squared for the market; the soft wood is chiefly removed, so that the season of felling does not seem as to them to be of much consequence. Besides, the timber is never so full of sap in summer as it is in spring and autumn, and therefore, next to mid-winter, midsummer may be the next best time for felling all kinds of timber-trees. Where the trees are disabused at the base a year or more before felling, the soft wood will be partially hardened; but this practice is by no means general in the north.

6958. Knowles, in a recent work on preserving the British navy, the dry rot, &c. after collecting the opinions of all the ancient and modern authors who have written on felling timber, concludes, that the common mode of cutting in the north contains less of sap or of the vegetable juices than those cut down at any other season of the year, is not true; and that the method of barking standing trees in spring, and not felling them till the succeeding winter, has not in any way realised the expectations formed of the practice. In all the directions given the sawyers have at length acknowledged that the best mode of seasoning is to "keep it in air, neither very dry nor very moist; and to protect it from the sun and rain by a roof raised sufficiently high over it so as to prevent this by this and other means, a rapid rush of air." (Inquiry into the Means of preserving the British Navy from Dry rot, &c. by Knowles, Sec. to the Con. of Surveyors, chap. iii.)

6959. The operation of felling is performed either by digging an excavation round the stem, and cutting the roots at two or three feet distant from it, or by cutting over the stem at the surface. By the former mode the root is obtained for use, and the ground more effectually cleared and prepared for the roots of other adjoining trees, or whatever crop is to follow. Where the tree is intended to stoile, which can very seldom be advisable in the case of cutting full-grown timber, or where there is some nicey in taking it down so as not to injure other trees or adjoining objects, it is cut or sawn over, and the root, if to be removed, dug out afterwards. In cutting large trees, in order to make the tree fall the way required, enter the cross-cut saw on that side of the tree it is intended to fall, and cut it about a third part through; then enter the saw at the other side, and when it is cut so far as to admit a wedge, place the wedge exactly opposite the way you
want the tree to fall, and keep driving it slowly till the tree is nearly cut through.”

(Montehunt.)

6930. Disbranching. The tree being felled, is next divested of its branches, which are sorted into fence-wood, fuel, ton-wood, &c. according to the kind of tree; and the trunk is generally preserved as entire as possible for the purchaser. Sometimes it is cut in two, and the root-cut, or but-end, being the most valuable, is sold for one class of purposes at a higher price, and the top-cuts for others somewhat lower. Sometimes timber is purchased by private contract by the foot or load in a growing state, or after being cut down; in other cases regular sales are made annually, and the produce exposed for sale by auction. It is measured by the cubic foot, fifty of which are a load; and the calculated tables and 

6931. The roots of trees are the last product we shall mention. These should, in almost every case, be effectually eradicated; to aid in which, in the case of very large roots, splitting by wedges, retting by gunpowder (1941.), tearing up by the hydrostatic press (fig. 211.), or by a common lever and triangle (fig. 666.), may be resorted to. Some compact ash or oak roots are occasionally in demand by smiths, leather-cutters, and others; but in general roots should be reduced to pieces not exceeding three feet long, and six inches in diameter, and put up in stacks not less than three feet every way, but commonly containing two cubic yards. These, when dry, are sold for fuel, or reduced to charcoal on the spot. In eradicating and stacking up coeppice-woods, it is common to allow a certain sum per sack, something for every acre of ground cleared; and if there are no trees to bark, the allowances are also made for the poles, faggots, &c. so that no part of the operation is performed by day-work.

6932. The usual method of charring wood is as follows:

6933. The wood being collected near the place intended for the operation, and cut into billets, generally about three feet in length, the pits or stacks are usually formed in this manner: A spot, adapted for the purpose, of about twenty feet in diameter, of a conical form, is selected, and after being properly levelled, a large billet of wood split across at one end, and pointed at the other, is fixed in the centre of the area, with its pointed extremity in the earth, and two pieces of wood, inserted through the clefts of the other end, forming four right angles; against these cross-pieces, four other billets of wood are placed, one end on the ground, and the other leaning against the angle. A number of large and straight billets are afterwards laid on the ground, to form a floor, each being, as it were, the radius of the circular area; on this floor, a proper quantity of brush or small wood is strewn, to fill up the interstices, when the floor will be complete: and in order to keep the billets in the same position in which they were first arranged, pegs or stumps are driven into the ground, in the circumference of the circle, about a foot distant from one another; upon this floor a stage is built, with billets set up on one end, somewhat inclining towards the central billet, and on the tops of these another floor is laid, in a horizontal direction, as the billets of shorter billets, as the whole is intended, when finished, to form a cone. The whole is then coated over with turf, and the surface generally plastered with a mixture of earth and charcoal-dust.

6934. Previous to the operation of setting fire to the pile, the central billet in the upper stage is drawn out, and pieces of dry combustible wood substituted in its place, to which the fire is applied. Great attention is necessary during the process, in the proper management of the fire, and in immediately covering up the aperatures through which the flame obtrudes itself, until the operation be concluded, which is generally effected in the space of two or three days according to circumstances. When the charcoal is thought to be sufficiently burnt, which is easily known from the appearance of the smoke, and the flames no longer issuing from the vents; all the aperatures are to be closed up very carefully, with a mixture of earth and charcoal-dust, which, by excluding all access of the external air, prevents the coal from being any further consumed, and the fire goes out of itself. In this condition it is suffered to remain, till the whole is sufficiently cooled; when the cover is removed, and the charcoal is taken away. If the whole process is skilfully managed, the coal will exactly retain the figure of the pieces of wood; some are said to have been dexterous, as to char an arrow, without altering even the figure of the feather. (Encyc. Brit. vol. v. art. Charcoal.)

6935. The method of charring wood, for the making of gunpowder, according to an improved system, adopted not many years ago, is however a much more costly operation, though the expense attending it is amply compensated by the superior excellence of the article when manufactured. It is done in iron cylinders, and in so complete a manner, that every particle of the wood is charred. The oily or tarry matter presents no inconvenience, and may, in the quantity goes, be made use of instead of foreign tar or pitch. This mode of charring wood for making gunpowder, is carried to the greatest perfection, near Petworth in Sussex, and there is a manufacture of a similar nature near Chester. (Gen. Rep. for Scotland, vol. ii. p. 332.)

6936. The valuation of trees forms a distinct profession, and can only be acquired after much experience; like other valuations of property, it depends on a great variety of considerations, some of a general, but the greater part of a local nature. All we shall here attempt, is to give a few general ideas which may be of use to the private cultivator or forester.

6937. In valuing any plantation, the first thing is to know its contents in acres; if this cannot be done, the number of plants must be counted. If a young plantation, the trees of which are unfit for present use as timber, is to be valued, then its value at any distant period, not exceeding twenty or twenty-five years, must be estimated; and whatever sum that estimate amounts to, the present value of that sum will give an idea of the value of the plantation, allowing liberally for accidents to the trees and other unforeseen circumstances. Thus, suppose a plantation of oaks, intended as copse, or actually established as
such, to have grown four years, its present value would be next to nothing; but if arrived at its twentieth year, it would fetch fifty pounds per acre. Then the question is, required the present value of fifty pounds, due sixteen years hence, the market price of money being five per cent.? and this, according to any of the modern annuity tables (say Bailey's, 4to. 1808. tab. iv.) is 22l. 18s. This principle is applicable to all kinds of valuing by anticipation; and there is no other mode of valuing applicable to young plantations. The benefits derived from the trees in the way of shelter and ornament, are to be estimated in valuing the territory, and are foreign to the present purpose, which has for its object tree-

6968. In valuing saleable trees of any kind, their number per acre, or their total number by enumeration being ascertained, and the kinds and sizes classed, then each class is to be estimated according to its worth as timber, fence-wood, fuel, bark, &c. 8 In a copice-wood which cannot readily be measured, the reducting the stems is a two step process. First, to cause two moves round as many of the stools as it will enclose, the one man standing still while the others move round a new number of stools, and count always the stools betwixt the two lines, causing the one man to move the one time with the line, whilst the other man stands still, and so on alternately. The valuator at the same time taking care to average every twenty stools they go over, and not losing sight of the counted stools. This way, too, is a very speedy and sure method of counting the number of trees in any plantation. Or, the stools of a copice-wood may be counted and averaged by two men going parallel to each other, and the person valuing going betwixt them; the two men putting up marks with moss, or pieces of white paper, on a branch of the stools; the one man going always back by the last laid marks, and the valuator always counting and averaging the stools betwixt the newly-laid and the late-laid marks; counting and averaging the stools always as the men go on, taking only twenty, or even ten stools, at a time. Those who have been in the practice of doing this frequently, it will be found very easy, and will be done very speedily, and with a very considerable degree of accuracy. The proper method of learning to do this correctly is, when a person cuts an oak wood for the first time (or, even were the work repeated several times), he should then, in order to make himself perfectly acquainted with ascer-

pecting the circumference is any thing, as twelve inches to twenty-four inches, then deduct two inches; from twenty-four to thirty-six, three inches; from thirty-six to forty, four inches; from forty to seventy-two, five inches; and above seventy-two, six inches.5 These deductions, he says, "will be found to answer in almost all trees; unless in such as are very large shoots, and big, and often only the stumps of the barks covered with moss, when an extra allowance is to be made." (Forestor's Guide, 180.) "Many persons," the same author observes, "in valuing measurable oak-trees, proceed on the data that every cubic foot of timber will produce a stone (sixteen pounds) of bark. This," he says, "is not always correct; and he states the following facts from his own experience, with a view to assist beginners in ascertaining the quantity of bark from various trees. "An oak-tree, about forty years old, measured down to four inches and a half side of the square, and weighing only the bark peeled off the timber that is measured, without including any of the bark of the spray, &c. every foot of measured timber will produce from nine to eleven pounds of bark. An oak-tree, of eighty years old, weighing only the bark peeled off the measurable timber, as above, every foot will produce from ten to thirteen pounds of bark. Every foot of large birch-timber, peeled as above, will produce fourteen pounds of bark. Every foot of mountain ash, as above, will produce eleven pounds and a half of bark. Every foot of white birch, and every old tree of birch that produce from nine to eleven pounds of bark. Every foot of larch fir, not exceeding thirty years old, will produce from seven to nine pounds of bark. The timber of trees, particularly the oak, is peeled out, every branch and shoot, down as small as an inch in circumference." (Forestor's Guide, 138.) The price of timber, like that of every other article in general use, varies with the supply and demand, relatively ascertained either by the timber-merchants of the different sea-ports; or by that of bark, charcoal, and fire-wood from the tanners and coal-merchants.

6970. To facilitate the measuring of standing timber, Montechast has invented a very ingenious machine. (fig. 667.) It consists of a wheel, or perambulator, about eight inches in diameter, with a bell (a) on the end of its axle; at the end of every foot gone over by the serrated circumference of the perambulator, this bell is struck by means of a spring (b); the sound of this bell will be heard from the top of the highest tree. A forked handle (c) works on the top of the main axle on each side of the wheel; one of a set of connecting rods (e, h) goes into it, and is fixed with a screw making a swivel joint, and by screwing the nut firm, the wheel can be set to any position, and it will work equally well any way. A small hand (d), in the circle of the triangular spring, points to the inches or quarters of an inch on the wheel, and tells what exceeds the inch after a lesser spring (e), which strikes at every inch, has struck the bell. The circumference of the wheel (f) measures two feet. The rods for working the measuring machine are each three feet long, and one inch in diameter, with connecting screws of brass on each end of them; so that as many as are
required for any length or height, can be easily screwed into each other. The other small rods for taking the length of the tree, as also of its branches, are only five eighths of an inch in diameter: each rod is three feet long, and goes together with connecting screws of brass. The rods are painted black, and divided into feet and inches, with white letters; so that by connecting any number of the rods together may be required, and by applying them to the tree or branches (k), you can take the exact length in a speedy, accurate, and simple manner. (Forester’s Guide, 207.)

6971. The value of the invention turns on the use of the wheel, in taking the girth of the tree. Thus, “after having taken the length of the tree in feet and inches, which length may be taken by the rods as already described, the girth is most generally taken at half the length, which girth we are enabled to take with the aid of the apparatus; this is by first putting up as in the figure, the rods together as will put it up to the required height; then, suppose there are no branches in the way, and having before made a mark on the bark of the tree with the small rods, the uppermost one having a small marking-iron in its end for that purpose; this mark is made where the girth is to be taken, and from where you rear the tree with the wheel being done, press the wheel round the tree, following it, and keeping it as level as possible, which the wheel will in a great measure do of itself, by its having teeth like a saw in the hem of the wheel, unless carelessly attended to. As the wheel goes round the tree, be sure to count the number of times the bell strikes, which it does at every foot; and when you see you have not another twelve inches or one foot more to run, to arrive at the place where you took your departure from, count the number of inches that it strikes over and above the last foot, and thus you will at once have the feet and inches that the tree is in circumference; of which take the fourth, and this gives you the side of the square: but when there are branches in the way of getting round the tree, you must have a spare handle for the machine (e, A), about two feet, or two feet six inches in length, and by altering the swivel-joint at the top of the first rod to any position required, the person working the wheel by the rods can stand in the same place, and put the wheel, half way round the tree, if it is very large, and by turning the swivel-joint, and reversing the wheel, at the same time sending it round the other side of the tree till it meet where it left off, and by counting the feet and inches as above, and adding the two together, you will at once have the extreme girth of the tree. When branches are to measure, or when branches are in the way of getting round the tree with the rods, the person with the small rods stands on the opposite side of the tree, and directs the person when to stop with the wheel. Thus, by a little practice in working the wheel, and paying attention to count the feet and inches as they strike, two men will measure growing or standing trees equally as accurately and expeditiously as if the trees were lying on the ground. In taking the girth with a line, you have first to put it round the tree, then you double it, and apply it to a foot-rule; you then take half for the side of the square, whereas this machine gives you the exact feet and inches from the top of the highest tree, without the help of any other rule” (Forester’s Guide, 208.)

Neither this machine, nor a mechanical dendrometer, invented about twenty years ago, though both of considerable value, and more general use in the former Measure of Bread. (Fig. 15.)

6972. The books of accounts for trees and plantations have already been mentioned. (2340.) Some have proposed measuring the whole of, or at least all the detached and hedge-row trees on an estate periodically; numbering each tree, and keeping a corresponding register, by which the proprietor, when at a distance, might give directions for cutting down particular trees, &c.; but this appears rather too much in the mercantile style for the dignified enjoyment of landed property, and does not promise any very great advantages.

Chap. VII.

Of the Formation of a Nursery-Garden for the Propagation and Rearing of Trees and Shrubs.

6973. Nurseries for rearing trees are commonly left to commercial gardeners, as the plantations of few private landowners are so extensive, or continued through a sufficient number of years to render it worth their while to originate and nurse up their own tree and hedge plants. Exceptions, however, occur in the case of remote situations, and where there are tracts so extensive as to require many years in planting. Besides, as Sang observes, “some are of opinion, that trees, in order to their being rendered sufficiently Hardy, should be reared on the soil and situation where they are ultimately to be planted; and if the design be extensive, and such as may require many years for its completion; a conveniently situated nursery is, in that case, highly desirable, not only as saving the carriage of plants, and facilitating the business of transplanting, but as increasing the chance of success, on account of the plants remaining a much shorter time out of the ground than if brought from a distance. If the situation, however, ultimately destined for the trees be cold, high, and bleak, and the soil of course various, some good, and much of it bad, or of an indifferent quality, there it would by no means be advisable to attempt the establishment of a nursery, and especially a nursery to raise plants from seeds. The chief properties of nursery plants intended for transplanting, consist in their strength and cleanliness of stem, and in their roots having a multiplicity of healthy fibres; and in order to obtain plants possessing these qualities, it is necessary to sow, and plant out to nurse, if not in rich, at least in mellow earth, and in a moderately sheltered situation.” (Plant. Kal. 20.) The following directions by Sang as to the soil, shelter, aspect, and fencing of a nursery-garden are equally applicable to such as are intended for private or commercial purposes:—

6974. In order to have a complete nursery, it should contain soils of various qualities, and not less than eighteen inches or two feet deep; the generality of it should be light friable earth; a part of it should be
of a clayey nature; and another part should be mousy. Each of these will be found peculiarly useful in the raising of the different kinds of young plants. The whole should be well drained, and trenched, and cropped with turnips, and other vegetables for one or even two years previously to sowing tree-seeds. For transplanting, it may be used the first year. A nursery may certainly be over-sheltered; but this is likely to happen only in the case of its being very small; for, if it extend to several acres, unless it be surrounded by very tall trees, the area will be considerably exposed. No part should be either too much exposed, or too much sheltered. Any aspect is as good as east and west, following the course of the sun; but a south aspect, on the unequal surface is most likely to contain the various soils above mentioned. A nursery should, therefore, in general, rise from a level to a pretty smart acclivity; yet no part of it should be too steep, because it is in that case very troublesome to labor. The nursery-ground may be sufficiently fenced by a stone wall, or even a hedge six or eight high; and if it be of small size, an acre or thereabouts, it will require no other shelter; but if it extend to four or five acres, it must have dividing hedges properly situated, to afford shelter over the whole area. The fence, whether of thorns or stone, should be made proof against the admission of hares or rabbits. It should be subdivided into compartments and borders, of proportionate size to the contours of the area, by walks. The compartments should never be encompassed with large trees, as apples, pears, or the like; because, being already established in the ground, they never fail to rob the young trees of their food, and to cause them to be poor and stunted, unworthy of being planted in the foreground. Very conveniently, there is a roll of ground, or to have a small pond, fed by a spring or a pipe, for the purpose of watering. (Plant. Kat. 22.)

6755. In preparing the soil for the culture of trees it will be advisable to trench it to its full depth, and "necessary," the same author continues, "to give it a good dressing of lime or marl and dung in compost. Rank manures, such as stable-litter, should not be applied to nursery-ground, at the time of sowing, with nursery articles; but if it be necessary to enrich it, this should be done by a manured crop of onions, turnips, lettuces, or the like. Potatoes should never before go a crop of seedlings, even of the corny sorts, as ash, oak, or chestnut; because potatoes never can be taken clean out of the ground; and, as they are indelissible to pull up those which rise among the tree-seedlings, many of these unavoidably come up along with them. Hence, crops of lettuces, turnips, cabbages, or the like, should rather precede the crop of seedlings. The best kind of management in this particular case, is to interchange the crops of these vegetables; and generally, perhaps, with the exception of maize, and some sorts of seedling-plants, alternately observing to sow all small seeds, in particular, if not fed a rich, at least in a fine tilth. (Plat. Kat. 24.)

6766. For a private nursery, he continues, "no place, certainly, can be more eligible than a field, which, when used as a kitchen-garden, and plants put in, will be thus, or as a garden, for sale. As for the purposes of nursery, and one or two acres were also required for extra kitchen-ground, or for green crops for cattle-feeding, it would be proper to enclose five or six acres, less or more, according to circumstances; by which means two important objects might be obtained, viz. land of a good quality, and fine tilth, for the raising of green crops; and, at the same time, an equal amount of land available for the purpose of occupying the ground as above advised, in the double character of a kitchen-garden and nursery."

6778. In a cold climate, or blusk situation, "with a poor barren soil, we would by no means advise the raising of seedlings, either in public or private nurseries. It will be found a cheaper, as well as a more rational way to purchase young trees or shrubs from a firm, to have them brought to the nursery; and, even, in this case, a piece of the best, and most sheltered land in the situation, will be necessary for the purpose." (Plat. Kat. 23.)

6779. A rotting-ground will be required for the preparation of certain seeds, by mixing them with sand, ashes, or soil, and leaving them there for different periods, from six months to two years, to rot off their interior coverings. On a small scale, a portion of the compost-ground of the kitchen-garden may be used for this purpose. If the scale is large, an area of a few square poles should be set apart for bedding-in plants taken up for replanting, or what is called setting in by the heels, or shoughing; this is generally called the bedding-ground or (in Scotland) the shoughing-ground.

6894. Buildings. If the situation of the nursery be near to the kitchen-garden, and the latter have the proper office-buildings (1701.), no other erection will be required for the nursery than a working-shed for ordnance, a commodious round-house for propagation, and a frame or frame without glass for propagating; and, even, in this case, a piece of the best, and most sheltered land in the situation, will be necessary for the purpose." (Plat. Kat. 23.)

6811. Stocking with plants. The ground being arranged, and prepared by one or more vegetable crops, the next thing is to stock it with stools, or stock plants, to propagate from by layers, and to procure stocks for grafting or budding, but occasionally, for private trees. In the nursery-garden, of ornamental trees and shrubs (6840. to 6871.), given in the preceding book; and in the general index at the end of the work will be found the particular mode of propagation, and the requisite soil for each tree and shrub; by inspecting these sources it will be seen what plants must be procured for stools. If the nursery is near to the main forest, the few, excepting some of limes, poplars, and planes, will be required; but, if tender trees and shrubs are to be reared, the number will be more considerable. Plant the tenderer sorts in the sheltered borders, and the more hardy in the open compartments; the tree kinds may be planted to the north of the way, and the shrub sorts to the south, in table soils. Stocks for grafting, whether for fruit or barren trees, are to be planted in nursery rows, according to their kinds; those for inarching round the parent plant (2007.) or in pots.

Chap. VIII.
Of the Culture and Management of a Nursery for Trees and Shrubs.

6982. The principal objects of culture in a private tree-nursery are the hardy trees and shrubs of the country, which produce seeds; and the great object of the private nursery-gardener must be to collect or procure these seeds, prepare them for sowing, sow them in their proper seasons, and transplant and nurse them till fit for final planting. We shall arrange the principal trees and shrubs which ripen their seeds in this country; as cones, nuts, berried stones, berries with small seeds, leguminous seeds, and small soft seeds.
Before treating of the gathering, storing, separating the seeds, sowing, and nursery culture, of each of these general divisions, it is essential to remark, that in collecting every kind of tree-seed, preference should be given to that produced by trees the largest and most perfect of their kind, and to the fullest and best-ripened seeds on these trees. The reasons have been too frequently given in this work to require repetition.

Sect. I. Coniferous Trees and Shrubs, their Seeds, Sowing, and Rearing.

6893. The principal hardy coniferous trees and shrubs are as follow:

- Juniperus virginiana, December
- Cupressus sempervirens, January
- Pinus strobus, October
- Abies, November
- Pinus sylvestris, November
- Pinus pinaster, November
- Pinus canadensis, November
- Thuya occidentalis, November

6894. Cones may be gathered in any time between the ripening season and the following April; but the sooner they are gathered the better, as they supply work for the regular hands of the establishment in bad weather during the winter months; or admit of giving industrious money-making persons work by the job in the winter evenings. The general mode of separating the seeds is by kiln-drying, in the same way as in drying malt, but applying a more gentle heat.

6895. The cone-kiln is constructed after the manner of a common malt-kiln: the bearers should be about nine feet distant from the fire, and two inches apart. A wire cloth is spread over them from side to side, and the cones are placed above the wire cloth on the bearers. The door is then applied, and regularly kept up till the cones become opened. During the time of drying, the cones must be frequently turned upon the kiln; and when the seeds begin to drop out, they must be removed to the seed-lofts, and sifted till all the seeds which are loose fall out, and be taken from among the cones. The cones are afterwards to be thrashed severely with failis, or passed through a hand-threshing machine, and sifted as before, and so on, till the seeds are taken out as completely as possible. It is, however, a safer method to split the larch-cones before putting them into the kiln. This operation is performed by a small two-manual spatula, sharpened at the point and cutting-angles; and held like a shoemaker's awl. The cone is held by the fore-finger and thumb of the hand, upon a flat piece of wood, while, with the other, by the splitter, it is split up from the great end; and afterwards each half is split up the middle, which parts the cone into four divisions. This is by far the best and least destructive to the seeds of all the methods of splitting; for when exposed to the heat, it is suddenly opened, and readily discharges the seeds; which, consequently, are less injured by the fire-heat. Besides the above method of splitting, there are others. Some people use a cone-mill, which has large sharp teeth in a conical cylinder, and others fixed in a corresponding roller. The mill is brought by turning the roller by a horse, and by means of this machine, the destruction is very difficult to work, and bruises the seeds very much; many of which are of course destroyed. We have several times made use of the common improved bark-mill, for separating the seeds from larch fir cones; but the cones are thus much compressed and bruised, that the seeds suffer exceedingly; and we would by no means advise it: indeed, among all the methods which we have known adopted, to perform the painful and laborious work of extracting of the seeds of the larch, the plan of splitting them singly is much the best and safest for the seeds, and ought to be adopted by every one who has occasion to use only small quantities of seed. None of the other kinds of cones require so much labor as the larch, excepting, perhaps, those of the cedar of Lebanon, and black American spruce. Cones, which have given out all their seeds, are generally, and very properly, used as fuel for drying other cones. This sort of fuel requires the attention of a very steady feeder; indeed, the most careful and attentive are apt to be defeated in the work, if they are not sufficiently acquainted with the nature of such cones. Cones on fire, from the resinous nature, and tendency to flames, of the empty cones used for fuel. Such kilns should, therefore, be erected in situations far removed from a dangerous neighborhood.

6896. The cones of Scots pine, the larch and the spruce, "are the principal kinds which are opened by kiln-heat. The cones of the silver fir, the balm of Gilead fir, and the Weymouth pine, give out their seeds with very little trouble: indeed, if they be not gathered soon in autumn, and kept from severe weather, they will fall to pieces of their own accord. Seeds of the white American spruce are only procured from those cones on fire, from the resinous nature, and tendency to flames, of the empty cones. Cones of the black and red spruce are brought from America, and sold in the state of cones. These should be split, and exposed in a sieve tilted before a gentle fire, with a sheet of paper below the sieve to receive the seeds as they fall out. The seeds should be removed every quarter of an hour; because they are more or less very easily injured by the heat."

6897. The cones of cedar of Lebanon "should be kept for one year at least, after they are taken from the tree, before the seed be attempted to be taken out. This is necessary, on account of the soft nature of the seeds, and the great quantity of resinous matter which the cones contain when growing, and which is discharged by the keeping. The best way to take out the seeds of the cedar, is to split the cone by driving a sharp conical piece of iron through the heart of them. This work, as well as the taking out of the seeds is greatly facilitated, by steeping the cones in water for a day or two, previous to splitting them. The cones are then taken out of the water, and dried in a well-ventilated place. The cones of the cedar are brought from the Levant, and may be purchased with safety for seed, although it be several years since they were taken from the tree." (Plum. Kat. 325.)

6898. Sowing. April is the best season for all the species; the soil should be in excellent condition, well mellowed by the preceding winter's frost and snow, carefully dug and raked as fine as possible. All the sorts are sown in beds, excepting the cedar of Lebanon and some pines; and the manner of sowing is by cuffing or bedding in, already described. (1875.)

6899. The soil for the Scotch pine, before being dug over in February, should be thickly coated with rotted hot-bed dung: the seeds should be sown so as to rise at the distance of a quarter of an inch from one another. The best preparation for larch-seeds is a previous crop of two-years' seedling Scotch pines, and next, a similar crop of the larch. The soil should be trenched by means of a hoe; for the seedling this is the most proper way of working. If no trenching be previously done, cover them with a light roller along the bed, to press the seeds firmly into the earth; then cover a quarter of an inch thick. The larch should rise at the same distance as the Scotch pine; but the seeds being generally more or less in separating, many do not come up, and they are therefore sown a little thicker than the other.

6900. The seeds of the spruce fir are to be treated like those of the Scotch pine; and the balm of Gilead
fir-seeds, like those of the larch, only the covering should not be less than half, nor more than three quarters of an inch.

The seeds of the silver fir and pinaster require the same sort of treatment as those of the larch. 

"They must not be sown to rise nearer one another than three in an inch. The covering should be a full inch thick, and performed with great accuracy: for if any of the seeds be left too lightly covered, or if the covering be too deeply covered, they will alike be destroyed." (Plant. Kal. 332.)

6982. The Home Gardens. The stone pines may be treated like those of the Scotch pine, but the former covered three quarters of an inch thick, and the latter an inch and a quarter. Sang states, that the only way to get stately trees of these, as of most of the pine tribe, is to sow them where they are to remain afterwards. 

6983. The white American spruce-seeds "are smaller than those of any of the preceding kinds, and therefore require a lighter covering than any of them. One fifth of an inch is quite sufficient. They should be sown on a piece of fine dry sandy loam, and be covered with earth of rotten leaves of trees to the above thickness, by sifting it upon them."

(Plant. Kal. 333.)

6984. The seeds of black and red American spruce fir "are very small and tender. They are still smaller than the seeds of the white American spruce, and therefore require a covering still lighter than mentioned for it. The black and red American spruce should be sown on rich boggy earth, which has been made light by some species of grass. They should be covered very lightly, by the addition of white sand answers best. This should be sifted over the seeds with a fine sieve. Neither of these American spruces will allow the roller to pass over them previous to covering. The whole of them should be shaded from the mid-day sun in the time of coming up, and for some time after, by means of hoops and matting, or spruce fir branches stuck in the opposite alleys, so as to form an arch over the beds." 

(Plant. Kalen. 334.)

6985. Cedar of Lebanon seeds should be sown in boxes of light sandy loam; or on a spot of properly prepared well watered soil, and covered half an inch: the red and white cedar-seeds may be similarly treated, covering a quarter of an inch thick. Arbor-vitae seeds will come up best under a frame or hand-glass: they should be sown on light sandy soil, and covered a quarter of an inch.

6986. The strictest attention should be paid to the foregoing directions, both in regard to quality of soil, and to the methods of treating the seeds. The growth of the young resins is very slow, and they are all very tender in infancy. The raising regular crops of this tribe is, therefore, justly reckoned the masterpiece of nursery culture in the open ground; and is supposed to be best understood in the northern counties.

6997. Transplanting. This tribe benefit less by transplanting than the non-resinous trees; and where circumstances admit, the better plan is, after the seedlings have stood two years in the seed-bed, to remove them where they are finally to remain. The exceptions are those sorts which are transplanted into pots, as the cedars and cyresses, and some of the more delicate pines, which may be kept in the nursing state, in pots, several years, as their roots can be turned out entire. About the middle of April is the proper time for transplanting all the resinous tribe, excepting the larch; and when drawn out by the hand, they may come up with all their fibres entire. The ground, which must be mellow, need not be so rich as for sowing the seeds; being previously prepared, they should be immediately planted in the trench manner. (2085.) The Scotch pine is generally planted in lines twelve inches apart, and the plants a foot distant in the lines; if intended to remain two years in the lines, they should be placed six inches apart in the line; but they always rise with the best roots, after being one year transplanted. The spruce and balm of Gilcird should generally be transplanted at two years; but, if weak in the seed-bed, may remain till the third year. They should be planted at the same distances as the Scotch pine, in humid rich earth. The silver fir may be treated in the same manner, but it requires rather more space. If to be nursed only one year, they may be planted in lines nine inches apart, and at six inches’ distance in the lines; but if to remain two years, then fifteen inches between the lines, and eighteen inches in the line will be necessary. The Weymouth pine should be transplanted at two years into a well pulverised, rich, and sub-humid soil, where it should remain two years before final planting; distance between the lines twelve inches, and from plant to plant eight inches.

6998. The pinaster and stone pine generally rise to well sized plants the first season after sowing, and should then be transplanted into a rich well comminated soil, rather sandy and dry, at nine inches between the lines, and four inches apart in the lines. After remaining there one year, they should be removed to their final situation. Great care is requisite in moving these plants, especially the stone pine, as they are easily injured in a very long root.

6999. The white American spruce, after remaining two years in the seed-bed, should be nursed two years in rich sandy and rather dry soil, in lines distant twelve inches, and the plants six inches apart in the lines. The black and red American spruce are much more delicate than the white. After being two years in the seed-bed, they should be placed six inches apart in the lines. They should stand for one year; at the end of this period, they should be lifted and planted in rows at the same distances as the white American spruce.

7000. The cedar of Lebanon, when one year old, should be lifted and planted in pots of the finest soil; or for potting, in lines distant the same distance as the silver fir; after being two years nursed, it should be removed to its final situation, as it never does much good if planted finally at a greater age, unless in pots, which is much the best method. The red and white cedars and cypress may remain two years in the seed-bed, and then be transplanted into the cedar of Lebanon.

7001. The larch may be moved from the seed-bed into the nursing lines, at one or two years. The soil to receive them should be soft, tender, and prepared by a crop of esculent vegetables with dung the preceding season; but they should never be planted in land newly manured with fresh dung. One year’s seed-bed aged soil; the second one year, and then the third one year. If planted in the fields, one year, five inches; the second year, three years, five inches, and fifteen inches between the lines. The two years’ seedlings should be sized, as in the seed-bed they never all rise to the same height; the larger size may be placed six inches apart in the lines, and twelve or fourteen inches between the lines, to stand one year; the smaller, at five inches, and a foot, for standing the same period: they should then be removed to their final situation.

7002. Care of the roots. No description of tree-plants receive so much injury from the loss of roots;
from the roots being exposed to the air by being kept long out of the soil; or from compression and exclusion of air and moisture by being kept in close bundles, or thick layers, as those of the resinous tribe; they should therefore be finally planted as soon as possible after removal from the nursery; and, indeed, whenever it is practicable, no more should be taken up in one day than can be planted that day or the next. Nor are any plants more easily deprived of the vital principle, by packing and carriage either by sea or land; though, being all evergreens, the larch, they do not readily show it. This has been stated to us, by experienced planters in Wales and other parts of England, as the reason why so few trees are finally produced from the immense numbers of Scotch pine and larch fir annually sent there by the Scotch nurseries.

7003. Pruning is not required by any of the resinous tribe in the nursery, unless to pinch out a contending leader, or amputate a bruised part of the root or top.

Sect. II. Trees and Shrubs bearing Nuts, Acorns, Masts, Keys, &c. their Sowing and Rearing.

7004. The principal hardy trees bearing nuts, acorns, masts, &c. are the following: —

<table>
<thead>
<tr>
<th>Tree</th>
<th>Sowing Date</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>Quercus prinus</em>, November</td>
<td><em>Fagus sylvatica</em>, September, October</td>

<tr>
<td><em>Aesculus hippocastanum</em>, October</td>
<td><em>Corylus avellana</em>, October</td>
</tr>
</tbody>
</table>

7005. Gathering and keeping. These being gathered, if circumstances permit, should be immediately sown; but where this cannot be done, or where they are to be sent to a distance, they should be thinly spread in an airy loft till thoroughly dried, when they may be preserved till spring in bags or barrels, or sent off to any distance in these or other packages. When the seeds of the ash, sycamore, platanus, and hornbeam, are only to be kept for the purpose of spring sowing, the best plan is to take them to the rotting-ground (6979.), mix them with their bulk of dry sand or ashes, spread them in a stratum of ten inches in thickness, in the form of beds, cover with sand to the same thickness, and leave them in that state till wanted for spring sowing.

7006. Sowing. The bedding-in manner (6091.), or by drills, may be adopted for all the kinds. Acorns, horse and Spanish chestnuts, almonds, and hazel-nuts, should be sown in February, in strong loam, in good heart and well comminuted: the seeds should be placed half an inch apart, and covered two inches thick. Walnuts require a similar soil and covering, but should be placed two inches nut from nut. Ash-seeds will come up in soil of middling quality, but it should be well dug, and in an open situation, that the plants may not be drawn. Place the seeds half an inch apart, and cover one inch. Sycamore-plants when young being liable to be killed by the frost, the seeds should not be sown till the end of March or beginning of April; they should be sown in exposed, dry, sandy soil, an inch apart, and covered one inch in thickness. On rich moist land they will rise so tall and soft, that the extremities of their shoots will not ripen in autumn, and the plants will in consequence be unfit for use. Beech-plants, when newly risen, are still more tender than those of the sycamore kind, and therefore should generally be sown in April, but not later than the middle of the month; for if very dry weather set in, they will not rise till the following spring, and so have a great chance of them perishing by the frost. The soil should be tender and rich, previously under a culinary crop with dung; and it should receive a small dressing of well rotted manure previously to digging for seminaria. The seeds should lie an inch apart, and be covered a full inch. The best time for sowing the hornbeam is in October; but it may also be sown in February: the soil should be light, but not very rich: the bed form answers best; the seeds should lie half an inch apart, and be covered half an inch in thickness. The plant is seldom raised from seeds; but when this is done, a soft peat-earth soil is the best, and the covering should not be more than a quarter of an inch. The seeds of the bladder-nut, if sown as soon as gathered, will come up the following spring; if not, a part will not rise till the second year: sow in light rich soil, and cover an inch and a half deep.

7007. Transplanting. The operation of loosening the plants, sorting them into sizes, and pruning their roots and tops, require to be first performed. As these plants have generally long and strong tap-roots, these require to be cut in the operation of loosening; which, for this purpose, must be performed with a sharp spade, and care taken in thrusting it down, that the root is not cut too high; care should also be taken to preserve uninjured all the lateral fibres. In sorting the plants into two or three sizes, the fractured tap-root of each must be cut smoothly off with a sharp knife, and any side shoots on the stem cut close off. If the plants cannot be immediately planted, they may be laid in by the heels, or shoughe; that is, thickly bedded in the bedding-ground (6979.) till wanted. Here they may remain in layers not more than three or four inches thick, for a month or two in the winter season; and for a week or two even in February and March. None of the kinds should remain in the seed-bed longer than two years; but in drills they may remain three years; and more especially if the operation of tapping be performed; that is, cutting through their tap-roots about eight inches below the surface. "This is most effectually and readily done by two men with
sharp spades; _cutting_ or cutting the ground obliquely with their spades, on each side the line at once, and exactly opposite to each other. After this operation has been performed, the plants should be made firm, by a person treading the rows with a foot on each side. These kinds, so tapped, will, in the course of the following season, in consequence of being thus root-pruned, push many more fibres on the upper part of their roots, than they otherwise would have done; and thus will the plants be better fitted for being transplanted into shallow soils, or indeed into any soil, than they would have been by being allowed to remain in the ground untapped till the time of lifting.”

(Plant. Kaf. 135.)

7008. _Trench-planting_ is decidedly the best for all plants to be placed in lines; but more especially for ligneous sorts. Dibbing in is an easier and more rapid mode; but by trench-planting the fibres are spread out and regularly disposed on each side of the main root; whereas, by dibbing, as Sang observes, they are “huddled together into a hole probably not more than an inch and half in diameter.” Dibbing, however, not being suited in the case of many such seedlings as have been robbed of most of their fibrous roots, by being pulled out in thinning beds intended to stand for two years.

7009. _The age at which most of these sorts should be transplanted_ is one year; and the soil most desirable for removing them to, is the same as recommended for the seed-bed. The distances between the lines and the plants in the line depend partly on their kinds, but principally on the length of time they are to stand before retransplanting or final removal. The larger-growing broad-leaved sorts, as the chestnuts and walnuts, to stand only one year, should not be nearer than eighteen inches by six inches; and the oak, ash, beech, &c. not nearer than fourteen inches by three inches; if to stand for three years, the inter-spaces may be two or three inches more; something depends on the openness of the situation, and a good deal on the soil. The judicious nursery-gardener will consider all the circumstances, and adopt such variations of the ordinary distances as shall produce plants with well ripened shoots, and numerous fibrous roots.

7010. _Pruning, culture, and taking up for final planting._ When the plants are to remain two or more years in the nursery lines without removal, dig the ground between the rows in winter. At midsummer cut off the lower side shoots; some defer this work till winter; but, besides the loss of sap avoided by midsummer pruning, the wounds heal the same season. In taking up for final planting, such plants as have been trench-planted must be loosened on the side which was solid at planting; if they have been in training for several years they should be lifted by throwing out a trench on one side, fully to the depth of the roots, and then putting in the spade on the opposite side, so as to get below all the roots.

Sect. III. _Trees and Shrubs with berried Stones, their Sowing and Rearing._

7011. The principal hardy trees with berried stones are the following:

7012. _Rotting._ The whole of these when gathered, require to be taken to the rotting-ground; mixed with their bulk of dry sand or ashes, laid in beds of ten inches in thickness, and then covered with ten inches of sand, light sandy earth, or ashes. Here some sorts, as the holly, will require to remain two years; the haw, mountain ash, and yew, one year; and the other sorts, one winter, or till the following February. During this time the beds of each kind should be uncovered, carefully turned over, and the covering replaced. The advantage of rotting off their exterior covering in heaps rather than in the soil, where they are to germinate, is the saving of ground; for though some of the holly and haw, for example, will come up the next or the second season after sowing, yet, by keeping them one or two years in the rot-heap, we are sure all the seeds will germinate the same spring in which they are committed to the soil. To the above general remarks, the gean forms an exception; for if sown immediately after being gathered in July, it will come up the following spring; but it will keep in the rot-heap a year. When any of these seeds are to be sent to a distance, instead of being carried to the rot-heap, they are spread thin in lofts, dried and packed in barrels; great care must be taken that they are sufficiently dried, otherwise putrescent fermentation will commence, and the vegetative principle will be destroyed by the heat evolved.

7013. _Sowing._ The season is generally February, and the manner by _bedding in_, as before. The haw, the most important of this class, should be sown in the lightest richest land in the nursery; and if not very rich, some dung may be added. Sow in beds three feet four, or three feet six inches apart; the seeds should lie within a fourth of an inch of each other, and be rolled with a roller of fifty or sixty pounds’ weight, and exactly the breadth of the bed, previously to covering, which should be one inch deep. If the seeds are too moist to admit of drawing a roller over them, beat in the seeds with the back of the spade. This operation of rolling in seeds not only fixes them in their places, so as to admit of applying the covering with greater freedom, but by consolidation with calculation to retain moisture, exclude too much air, and thereby promote germination. Holly and yew seeds should be sown on rich friable soil, shaded by a wall or by wattled
hurts, or other means, from the mid-day sun. The distance is the same as for haws; they should be rolled, or beat in, and covered not more than half an inch. If previously rotted for two years, they will all come up the following May; but if only one year in the rotting-bed, a part will not come up till the second year; in this case they should be sown thin, as the growing plants will impede the others in breaking through the soil. Mountain ash seeds require a fine and rather rich soil; the seeds should not lie nearer than an inch, and the covering should be only a quarter of an inch. The gean should be sown, as soon as gathered, in deep sandy loam, the pulp being previously bruised; it need not be very rich, but must be dug deep before sowing: place the seeds an inch apart, and cover three quarters of an inch thick. Gean-stones, which have been preserved in the rotting-ground for spring sowing, will not come up regularly the summer following, but a part will lie till the second spring. The advantage of sowing as soon as gathered, is therefore obvious. Great care should be taken not to sow the cherry for the gean, as the former is not nearly so well calculated for a timber-tree. The seeds of the common and Portugal Laurel, laurel-bay, mezereon, spurge-laurel, phillyrea, and the like, should be sown as soon as gathered, in rich soft soil, on a dry bottom: the seeds should be an inch apart, and be covered an inch. During the severest weather of winter, it will be advisable to protect them by hoops and mats. The seeds of the service, buckthorn, bird-cherry, and other species of prunus, rhamnus, and mespilus, may be treated like those of the laurel, but will not at all require so deep a covering, nor will any of them require protection in winter.

7014. Transplanting. What has been advanced on transplanting plants from nuts, keys, &c. will apply here. Most of these species being smaller, will not require so great distances between the rows and plants. All the deciduous sorts may be transplanted in February or early in March; and all the evergreen species from the middle of April to the middle of May; and during the month of August. The greatest care will be requisite in lifting evergreens from the seed-bed, where they have been already once moved, so as not to injure their fibres; and on no account should more be taken up at a time than what can be planted the same day. Select for them the soils most suitable to their nature (6974.) as far as the limits of the nursery will permit; and in general, rather prefer a sandy situation, especially for the holly, yew, and all the laurales. Hollies having few fibrous roots should be frequently transplanted; but this is not necessary with the yew, which has fibres in greater quantity. In transplanting the deciduous sorts, prefer narrow spaces between the lines, and wider intervals in the rows, to wide rows, and plants crowded in the row. One year's seedling thorns, for instance, to be nursed one year, may stand nine or ten inches by two inches; if for two years, twelve or fourteen inches by three or three and a half inches.

7015. For pruning, culture, and lifting for final planting, see nut-bearing trees, &c. (7004.)

Sect. IV. Trees and Shrubs bearing Berries and Capsules with small Seeds.

7016. The principal hardy berry and capsule bearing trees are the following:——

| Tilia europaena, November | Cornus mascula, October |
| Pyrus communis, October | — virginiana, October |
| — malus, October |

Sials.

Berberis vulgaris, September

Buxus sempervirens, September

Ligustrum vulgare, October

Elaeagnus latifolia, November

Europaena, November

Viburnum lastana, September

Opulus, October

Ribes grossulariafoes, September.

7017. Gathering and keeping. As this class of seeds are only wanted in small quantities, the most convenient way of preserving them is in the seed-loft or root-cellar in dry sand. They should be frequently turned over to separate the seeds from the pulp and husks, and cleaned by siftin and fanning early in February. For sending to a distance, they are to be treated like berried stones; or they may be separated and cleaned previously to deportation.

7018. Sowing. All of them require a soft and rather moist soil, with the exception of the box, which should have a soil rather sandy and dry. They may be sown in February, in beds, and covered not more than a quarter of an inch; and when the seeds first begin to vegetate, it will be an advantage to shade them from the sun, by wattled hurdles; place them across beds which lie north and south, and along those lying in a direction east and west.

7019. Their transplanting and future culture are the same as for the foreign division.

Sect. V. Trees and Shrubs bearing leguminous Seeds, their Sowing and Rearing.

7020. The principal leguminous trees are as follows:——

| Cyclus alpinus, October | Colutea arborescens, October |
| Robinia pseud-acacia, November. | —— crucenta, October |
| — pococilk, November |
| — media, October |

Sials.

Robinia caragana, November

Coronilla emerus, October

Cyclus nigricans, September

Sialis.]

Cyclus nigricans, September

Sessilifolia, October

Austriacus, September

Tomentosus, September

Iabrum, October.

7021. Gathering and keeping. These being collected are to be dried thoroughly in an
PRACTICE OF GARDENING.

PART III.

air loft, and the pods being afterwards threshed or opened, the seeds may be preserved in bags or boxes till spring, or sent to any distance.

7022. Sowing. The season for sowing all of them is February; the soil should be light, deep, and sandy, and the seeds placed an inch apart, and covered three quarters of an inch thick. This should be particularly attended to in the case of the laburnum, the seeds of which, being generally sure growers, if they rise thick, they lose their leaves about midsummer, become mildewed, and die. Attention should be paid not to intermix the tree-laburnum (C. alpinus, W. en.) with the shrubby sort.

Sect. VI. Trees and Shrubs bearing small soft Seeds, their Sowing and Rearing.

7023. The principal hardy trees with small seeds are as under:

Alnus glutinosa, November
Beech, alba, October

Populus nigra, May
— tremula, May

Cistus, various species, September
Philadelphus coronarius, October
Salix pentandra, August
— babylonica, June
Rhia cuspidata, and other species, July.

7024. Gathering and keeping. All these require to be gathered as soon as ripe, otherwise some are apt to drop out of their capsules, as the alder, birch, and lilac; and others to be blown away and lost, as the elm, poplar, willow, and sumach. They should be gathered perfectly dry, and spread thin in a airy loft, till fit to put up in bags or boxes, for keeping or deportation.

7025. Sowing. Most of the sorts may be sown immediately after being gathered, in which case they will be more certain of germinating; and a number of elms, poplars, and willows, will come up the same autumn. But as protection during winter will, in that case, become requisite, the better way, in general, is to defer sowing till March or April, when all the sorts may be sown in light rich earth, rather moist, and covered not more than half an inch. The principal tree of this class is the broad-leaved elm, which, where intended for two-year seedlings, which, in most cases, is the preferable age for transplanting, should be sown to rise at least two inches apart, as the plants grow with great vigor even the first year.

7026. Their transplanting and future culture are the same as directed for berried stones, keys, &c.

Sect. VII. Culture common to all the Classes of Tree-seeds.

7027. Insects and vermin. New-sown seeds of most kinds are greedily devoured by various descriptions of vermin. Mice attack "acorns, sweet chestnuts, hazel-nuts, walnuts, and holly-seeds. They not only eat them on the spot, but they carry to their retreats great numbers of the seeds of which they are most fond. The cheapest, and perhaps the most effectual trap for their destruction, is the well known but neglected fourth figure trap. (fig. 668.) The new-sown haws and mountain ash berries are a prey to the chaffinches, green linnets, and other birds. If the quantity sown be not great, the beds may be hooped over and covered with small-meshed nets. But if a great breadth of ground be sown, it must be constantly watched after sowing. If the watching be vigilantly attended to, for a few days immediately after sowing, the seed will not need much more attention till they begin to break the ground; at which period the watching should be closely and regularly continued. As they are always the strongest and best-ripened seeds which rise first, it is therefore of much importance to prevent these from being picked up." (Plant. Kalend. 230.)

7028. Weeds. Before the tree-seeds come up a crop of weeds will probably have made their appearance; these are to be removed when young, otherwise drawing out their roots will materially disturb the vegetating seeds. "It not unfrequently happens, that the land in which fir and larch seeds have been sown, becomes battered by heavy rains. This will certainly happen if rain fall immediately after sowing before the surface become dry; but if it once be fully dried after sowing, and before the rain fall, it will seldom or never batter. Suppose, however, the seed-beds are battered, so that the tender seeds cannot rise with freedom, the best way to relieve them is to draw over them a wooden roller, stuck over with lath-nails at half an inch distance, and driven in so as to remain half an inch beyond the wood of the roller. The roller should not be more than thirty inches long and not more than thirty pounds weight. By drawing this roller along the one side of the battered bed, while walking in the alley, and returning with it over the other, an ordinary-sized bed will be completely relieved. Some people rake their battered beds, in order to enable the seeds to rise. This is a most dangerous and destructive method of relieving vegetating plants. From their tender state, the smallest twist breaks them over, and consequently destroys them. We have experienced much advantage from using
the light armed roller, here recommended. It is, however, much better when no such are required. The surest way to guard against the need of such means, is to work the land when it is in a proper condition, and to sow the seeds in such weather as that the surface after sowing will be fully dry before rain come on. There is no dispensing with this precaution, when it is wished to secure an equal and good crop of seedlings."

(Plant. Kal. 367.)

7029. Birds. In May the pines and firs will begin to pierce the ground with the husks of the seeds still on their tops, and then watching the birds becomes of the utmost importance; not one ought to be allowed to light on the beds; to prevent which will require unremitting attention from break of day till sunset, for five or six weeks, till the plants are all up, and have thrown off their husks. After the nuts, mast, and haws have come up, they are no longer in danger from mice, but they may be attacked by snails, and grubs of beetles and cockchaffers at their roots. These are to be hand-picked.

7030. Watering and shading. In June severe droughts very often set in, and these are very prejudicial to small seeds, especially those of the resinous tribe, when rising through the soil. At this time watering and shading may be applied with great advantage, provided the former is accompanied by the latter, and daily attended to from the time it is commenced till rain falls. The best mode of shading is by the wattled hurdle. By the end of July the seedlings of most sorts will be out of danger, and excepting a few of the tender sorts specified as requiring protection in winter, or by a hand-glass or cold-frame, will require no other care but weeding till fit to be transplanted.

Sect. VIII. Of propagating Trees by Layers, Cuttings, Suckers, Grafting, &c.

7081. Layering is next to rearing from seeds the most general mode of propagating hardy trees and shrubs. The more common species of forest trees to which this mode is applicable, are the Acer Platanoides, pseudo-platanus, tartaricum, dasyacrum, opalus, negundo, and other species; Betula lenta, populifolia, and rubra; Fagus ferrarugina; Platanus occidentalis and orientalis; Populus græca, monolífera, and canescens; Tilia alba, americana, europaea, and pubescens; and Ulmus campestris, nemoralis, and suberosa. Some of these, as the poplars and planes, are also propagated by cuttings; but layers make the strongest plants. Whenever seeds can be procured, however, it is best to propagate in that way, as likely to produce the largest trees. The other trees propagated by layers, will be found in our Encyclopædia of Plants, and in the arboricultural catalogue; and also all the shrubs so propagated. The situations and distances for planting stools in the nursery have been already mentioned (6981.); and, as there is nothing peculiar in the operation of layering timber-trees or shrubs, we have merely to refer to the general directions as to layers and stools. (1993.) The young or preceding year's shoots of all the sorts above enumerated, if layered in autumn or winter, will be fit for being detached and planted in nursery lines by that time twelve months. They should be transplanted into well comminuted soil, as far as practicable, suitable to the nature of each; the distances should be regulated by the size of the layers and the time they are to be nursed. For ordinary purposes layers need not be nursed more than two years; but for single trees and ornamental plantations, they should be several times removed, and close pruned, till they have attained six or eight feet in height. Evergreen trees and shrubs, as being more tender than the others, should be layered in March and April, and from August to October. Some sorts root most freely when the wood is in a succulent state; and of such the current year's shoots are laid about midsummer. This is practised with Stuarta, Arbatus, Andromeda, Kalmia, Azalea, Magnolia, Alaternus, Phillryea, Laurus nobilis and sassafras, Zanthoxylum, Pyrus japonica, &c. The same practice is adopted with other free-growing sorts that it is wished to multiply as rapidly as possible; as the Rosa (6546.), Hibiscus, Loniceræ, Aristotelia, Mespilus, &c. Layers of the last sorts made during summer from the same year's shoots, will be fit to detach by the winter or the following spring; of the other sorts seldom sooner than the second August or autumn; but even then a season is gained, as the layers of those plants made in autumn, generally require to remain two years before they have made sufficient roots. The layers of all evergreens should be removed at the proper seasons for pruning, laying, or transplanting that tribe; that is, in April and May, and in August and September.

7032. By cutting is the next most general mode of propagating trees and shrubs, and the common forest trees generally so multiplied are as follow: Platanus occidentalis and orientalis; Populus angulata, balsamifera, dilatata, græca, monolífera, nigra, pendula, and trepida; Salix all the tree species; and Šambucus nigra. These are also propagated by layers, and a few of them by seeds; which last, it should never be forgotten, is by far the best mode where timber-trees is the object. The numerous tribe of shrubs propagated by cuttings, will be found in the Encyclopædia of Plants already referred to.

7033. The manner of forming and planting cuttings has been already described. (2063.) The season for deciduous and evergreen woody plants are the same as for layering; and as in the latter mode of
propagation, so in multiplying by cuttings, some sorts succeed best when the current year's wood is taken at midsummer; as for example, Laurus nobilis, benjoin, and sassafras, Bignonia, Euphorbia, Phlomis, Ross, Santolina, &c. Cuttings of some of these sorts, made of year-old wood in spring or autumn, require to stand two seasons before they have made sufficient roots to admit of their removal; by midsum-mer cuttings one year is gained. The same practice may be applied to deciduous sorts; but the plants produced are not so strong as by cuttings of ripened wood. All cuttings require to be planted in a shady situation, and sandy soil, dry at bottom; but kept somewhat moist by occasional watering in dry weather; their lengths are generally made in proportion to the length of the year-old wood, but seldom exceeding six or eight inches. The shoots of some sorts, as poplar, willow, honeysuckle, &c., are divided into several cuttings of this length. An inch of the former year's wood is often preserved in autumn-made cuttings; but this is not essential; as more important points are, making a smooth horizontal section at a bud, and in planting, pressing the earth very firmly to the lower extremity of the cutting. Midsum-mer cuttings should in almost all cases be covered with hand or bell glasses. The older, most willows, the Lombardy, and some other poplars, will grow from cuttings or truncheons of several feet long, and of several inches in diameter. "This method is occasionally adopted, when it is requisite to form expe-diously some rough plantation, to serve as a hedge or screen along an outward boundary. Cuttings for this purpose may consist of long slender rods of one or two years' growth, or as well of large trun-choons or stakes from three to six feet in length. Further, the willow, in particular, will increase from large pole-cuttings of from six to ten feet, planted out at once to form either pollard-stems, or be trained into full standards. (Abcrrombic.)

7034. The season for transplanting suckers into nursery lines, are those already mentioned as the most fit for moving deciduous and evergreen trees, originated by other modes. (6083. to 7023.)

7035. By suckers. A few common trees, and a number of shrubs are propagated by suckers. The timber-trees are the Ailanthus glandulosa, Robinia pseud-acacia, Populus canescens, alba, and tremula, and Ulmus campestris. Of hedge plants, the common sloe and other wild plums, crabs, and pears, are, or may be so propagated. Various shrubs are propagated by suckers. Suckers make better trees than plants raised from cuttings, and also very good hedge plants. To induce a tree to send up suckers, the horizontal roots may be laid bare, notched in different places, and the earth mixed with sand and replaced; a powerful co-operative would be to cut the tree over by the surface, by which means all the sap would be employed in root-shoots. At the end of one, but sometimes not till the end of the second season, the suckers will be fit to slip off, or to separate by the knife with a part of the parent root attached; they may then be pruned as required, and planted in nursery lines.

7036. Grafting, budding, and inarching, are modes applicable to a few hardy trees and shrubs. The common forest trees are the Fraxinus americana, Populus candidans, heterophylla, and lavigata, Pyrus Aria, Quercus exoniensis, and Ulmus campestris and suberosa. These, and the ornamental trees and shrubs so propagated, are worked on stocks of the more hardy species of the same or of the next allied genus; and, probably, make as durable plants for timber-trees as layers; by which mode the above enumerated sorts are also propagated. The stocks should be at least one year established, previously either to grafting or inarching; the operation for deciduous sorts is performed in spring at the rise of the sap. (2010.) Evergreens are almost always inarched either in April, or May, or August. Budding is performed in June and July, and is chiefly used in propagating the rose. (6553.) Some inarched sorts require two seasons before the scion can be detached from the parent plant.

7037. General culture and management of a private nursery. There is nothing material to be advanced on this head, but what has been already recurred to in this chapter, or in treating of the general management of the kitchen-garden. The first grand point is so to arrange the rotation of crops, that a crop of culinary vegetables shall intervene between every crop of trees, where that crop remains on the same soil two or more years; and between every two or three crops, where the crop of trees is lifted annually or the second year. The next thing is changing the surface of the soil, as in horticulture (2557.), weeding, stirring the surface, watering, shading, pruning, training, staking, and protecting. The important points of management are to procure the proper quantities of seeds or stools requisite to produce the quantity of trees to be annually furnished; to proportion the number of plants taken up daily to the number replanted in the nursery or forest the same day, and to attend to general order and neatness.

CHAP. IX.

Arboricultural Catalogue.

7038. In our arboricultural catalogue we mean to enumerate, and shortly describe, the principal timber-trees which may be cultivated with advantage as such, in the climate of Britain, and also the most useful plants for hedges. We shall arrange the whole as resinous, hard-wooded, and soft-wooded trees; including in each section the hedge plants belonging to it, and in the last, the willows proper for osier-plantations; the general culture of the trees contained in each of these sections, has been given in chapters III. IV. VII. and VIII.
Sect. I. Resinous or Coniferous Trees.

7039. The resinous forest trees are comprised in three genera belonging to the natural order of Coniferae, J.; viz. Pinus and Cuppressus, Monac. Monad. L., and Juniperus, Diac. Monad. L. The trees which are valuable as timber are comprehended under the genus Pinus, which comprises the three subdivisions of pines, larches, and firs. The first is distinguished by fasciculated leaves in different sheaths, but proceeding from the same sheathing base; the second by fasciculated leaves from solitary sheaths; and the third by solitary leaves. The branches of the whole genus are frondose or spreading, and caducous; those of the pine tribe spread the least; those of the larch tribe rather droop; and those of the firs are thin and much spread, and are peculiarly frondlike.

7040. The wild or Scotch pine, erroneously denominated Scots fir, is the Pinus sylvestris, L. (Lam. Pin. l. t. 1.) Pin, Fr.; Keifer or Förhre, Ger.; and Pino, Ital. (fig. 669. a) It is an evergreen sub-conical tree; the foliage inclining to dark-blue or grey; shorter and broader than those of the stone pine (b); it is common in most parts of Europe, particularly the northern countries, and is the only species of the genus indigenous to Britain, being a native of Scotland, and naturalised in England and Wales. Under favorable circumstances it attains the height of seventy or eighty feet: it flowers in May, and the cones are fit to gather in December. The finest pine-woods in Britain are at Invercauld, in Inverness-shire, and Gordon Castle, in Aberdeenshire.

7041. Use. The timber of this tree is the red or yellow deal of the north of Europe, and is the most durable and valuable of any of the genus, unless we except the common larch. The universality of its application to building and cabinet work has been mentioned: in Scotland, pine, Sange, states to be not inferior to any imported, either in cleanliness or durability, when it has been grown on a proper soil, and to a sufficient age. "But the planted Lowland pine," he adds, "is seldom applied to offices higher than that of roofed sheds or huts, lining of carts, lathing, or making of packing-boxes; while the natural or self-sown is fit for the finest purposes." The wild or grown wild pine, if properly pruned and grown to a sufficient age, as likely to equal that of foreign growth. The tree is of great value as a nurse-plant, being next to the common birch and bastard mountain ash, or mountain sopp (Pyrus hybrida), the most hardy timber. Among its minor uses we shall only mention the production of tar by incision.

7042. Varieties. Of these, several have been noticed by botanists, and some consider the P. maritima (esp. Wild.) as nothing more. According to Sange, the variety commonly cultivated is least worth the trouble. "The P. sylvestris, var. montana," he says, "is the variety which yields the red wood: even young trees of this heart are smooth and hard, and full of resin very soon. The late distinguished Don, of Forfar, exhibited specimens of cones of each variety to the Highland Society of Scotland, and likewise to the Caledonian Horticultural Society. The variety preferred by Don, is distinguished by the disposition of its branches, which are remarkable for their horizontal direction, and for smoothness of the trunk. The leaves are broader and shorter than in the common kind, and are distinguishable at a distance by their much lighter and beautiful glaucous appearance. The bark of the trunk is smoother than in the common kind. The cones are thicker, and much more durable than the common sort, growing freely in almost any soil or situation, and quickly arrives at a considerable size." Sang says, he has seen trees of this variety at Caristoun and Brechin Castle; and it is much to be wished that he or some other competent nurseryman, in that quarter, would collect the seeds, and propagate it extensively. Thouin (Notes sur la Culture de Pinus, Svo. 1819) mentions a variety, which he calls P. syl. var. pin de rigo, as affording the best timber. Whether the pine which forms the extensive plantations along the sea-coast at Bourdeaux, and is called by foreign authors, P. maritima, be a variety of P. sylvestris or a distinct species, does not appear to be ascertained. The plant is tender, and easily killed by frost when young; but its timber is said to be of excellent quality. (Redeitt's Planter, 220.)

7043. Soil and native site. "This tree is naturally the inhabitant of mountainous districts, and of rocky, gravelly, or poor sandy soils, where its timber becomes most valuable and durable. On the sides of mountains, the plants are stunted, and their wood is of inferior quality; on the heights, beside rapid rivulets or mountain torrents, it is found in high perfection; and if it stand single, it is of great beauty. In many parts of the Scots Highlands, where the soils are extremely various, and much mixed, the Scots pine has arrived at a good size, and often attained remarkable dimensions. In any kind of soil from a sandy to a clay, provided the substra- tum be not too poor for roots. It is grown in most parts of Europe; but in wet lilly soils, it ought never to be planted; because wherever the roots have exhausted the turf or upper soil, and begin to perforate the sub-soil, the tree languishes and dies." (Plant. Kal. 65.)

7044. Insects. The larvae of Noctua pinastri, L. (Xylena, Hub.) are deposited in the leading buds, and often forest the young shoots and leave the tree without a leader. The apalis pinii infests the tender shoots; and various dermestidae live in the bark, and perforate the soft wood.

7045. The Corsican pine (P. laricio, P. S.) is a native of the mountains of Corsica and is nearly allied to the Scotch pine. It is planted in the Royal Parks; planted in 1784 and 86 feet high in 1821, thus described by David Don. "P. laricio is a much handsome and finer tree than P. sylvestris with which however it in some respects agrees. It is of a more pyramidal habit, and its branches are shorter and more regularly verticillated. Its leaves are a third longer, and of a lively green, with their sheaths nearly as long as the leaf; the leaves are two rank straight, with depressed scales; and its bark is finer and much more entire. The enlightened Professor of Agriculture informed us, that it is equally hardy with P. sylvestris, and that its wood is much more weighty and resinous, and consequently more compact, stronger, and more flexible. It grows wild on the summits of the highest mountains in Corsica. It seems to bear cones very freely, which ripen nearly about the same time as those of P. sylvestris."

7046. The pitch or red Canadian pine (P. resinosa) (Lam. pin. 20. t. 4.) is an Ameri-
can tree, introduced in 1756, not unlike the Scotch pine, and "receives its name from the color of the bark. From the high geographical range of this pine, it is well adapted to associate with the P. sylvestris. It has been imported in the form of mastis into this country. Like the P. sylvestris, it affords an inferior timber on a damp and unsuitable soil." (Caled. Hort. Mem. ii. 367.)

7047. The pinaster or cluster-pine (P. pinaster, L.) (Lam. Pin. 9. t. 5.) (fig. 669. b) grows to the height of fifty or sixty feet, with broader, thicker, and longer leaves than the common pine (a) : the branches are also farther apart, and grow more horizontal than in that tree. As the tree advances in age it becomes naked and unsightly below; but the top grows highly picturesque, and may readily be distinguished in the landscapes of the Roman and Florentine painters. It grows naturally on the mountains of Italy and the south of France; in Switzerland it is cut into shingles for covering their houses, and also for making pitch. It flowers in April and May, and the cones are fit to be gathered in December. It was introduced in 1596, but never much cultivated, being less hardy and much less valuable as a timber-tree than the common pine. It is very picturesque, and well merits culture in that point of view. There are some large specimens at Culzean Castle, on the sea-coast of Ayrshire.

7048. The stone pine (P. pinea) (Lam. Pin. 11. t. 6, 7, 8.) (fig. 669. c) grows to a considerable height, with a straight stem and rough bark. The leaves are not quite so long as those of the pinaster, and are of a greyish or sea-green color. The cones are five inches in length, round, thick, and obtuse; the kernels are large, and frequently served up in deserts during the winter season in Italy and the south of France, and they are also much relished by the Chinese, for the same purpose. It is a native of the south of Europe; very common about Ravenna, and forming a distinguishing ornament of the villas of Rome and Florence. It was introduced here in 1570; but as the wood is not so resinous as most of the other sorts, it has been only cultivated for ornament.

7049. The swamp, Georgia, pitch, or long-leaved pine (P. palustris) (Lam. Pin. 27. t. 20.) (fig. 669. d) is a valuable and a lofty tree in America, affording planks, which, imported in this country, are valued 20 per cent. higher than any other American timber excepting the black larch. The leaves are a foot or more in length, produced in tufts at the ends of the branches, and having a singular appearance. It grows in a warmer climate than most other pines; and if it were found to produce equally valuable timber in the low warm situations of England, which it does in America, it would be a most valuable tree. It was introduced in 1730, but has been very little cultivated.

7050. The Weymouth or New England larch, commonly called Weymouth pine, (P. Strobus) (Lam. Pin. 31. t. 22.) (fig. 670.) forms the connecting link between the pine and larch tribe. It is one of the tallest of the genus, attaining in America the height of 100 feet and upwards. The bark is smooth and delicate, and the leaves soft and of a bluish green. Vast quantities of the timber, under the name of the white pine, are imported from America; but the tree seems to be of so delicate a habit, as to prevent our expecting it ever to become a large or valuable tree with us, especially in exposed situations. It was introduced in 1705, and has been a good deal cultivated, having formerly been supposed the most valuable tree of the genus, next to the common pine. The largest specimens are at Mersham-hatch, Sir E. Knatchbull's seat in Kent, and at Whitton Park in Middlesex.

7051. The cedar-larch, or cedar of Lebanon, is the P. cedrus, L. (Lam. Pin. 59. t. 37.) Cèdre, Fr.; Cederbaum, Ger.; and Cedro, Ital. It is distinguished from all other trees of the genus by its strong ramose branches, which, in some cases, deviate from the common character, and become irregular in shape, and permanent in duration. The general character of the shoot, even when the tree is young, is singularly bold and picturesque, and quite peculiar to the species. The tree is a native of the coldest part of the mountains of Libanus, Amanus and Taurus; but it is not now to be found in those places in great numbers. Maundrell, in his journey from Aleppo to Jerusalem in 1696, could reckon only sixteen large trees, though many small ones: one of the largest was twelve yards six inches in girth, and yet sound; and thirty seven yards in the spread of its boughs. The forest of Libanus never seems to have recovered the havoc made by Solomon's forty score thousand hewers: so that we have now, as Professor Martyn observes, probably more cedars in England than there are in Palestine. The tree is supposed to have been introduced here in 1683. The oldest specimens are
two in Chelsea-garden; but there are more magnificent ones at Whitten Park, Zion House, Pains-Hill, Warwick Castle, and other places.

7062. Use. The tree has been very generally planted for ornament, and from its branchy head, and its aversion to pruning, it is not likely ever to become a valuable timber-tree in this country. When planted for that purpose, it should, as Sang recommends, be sown in groves, and thus by proximity drawn up with few branches. Much has been said of the thorn, which borders on the miraculous; as far as experience has gone, it is greatly inferior to that of the common larch, or the wild pine. Its great use is as a single tree in lawns, where it combines beauty and singularity in a degree not to be found in any other tree. It has also an excellent effect in the margin of plantations, and one or two plants will give force and character to the front of round-headed trees, and effect a great deal even in the fronts and sky outlines of plantations with spiry tops. (fig. 560.)

7053. The common larch is the *P. larix*, L. (Lam. pin. 53. 35.) *Larix* or *Mölze*, Fr.; *Lerchenbaum*, Ger.; and *Laricio*, It. It is the only species of the genus, the leaves of which are deciduous; it rises to eighty or a hundred feet high, forming a narrow cone of small white-barked caducous, pendulous branches, with delicate drooping spray. It is native of the Alpine mountains, on the north sides of which, in hollows and chasms, it attains to its greatest height and thickness, and most durable timber. In returning from Italy, by the Simplon, the silver fir will be found in great perfection in the hollows on the south side, the common Scotch pine on the summit, and the larch in descending to the Vallais. It appears to have been cultivated by Parkinson in 1629; and Evelyn, in 1664, speaks of a tree of good stature, "not long since to be seen at Chelmisford, in Essex, (also mentioned by Harte,) which sufficiently reproaches our not cultivating so useful a material for many purposes." Harte, in his excellent essays, published in 1715, gives a figure of the larch, and strongly recommends its culture. It was first introduced into Scotland by Lord Kames in 1734 (Lam. pia. t. 35.), and afterwards in 1741, planted by the Duke of Atholl at Dunkeld, and these last trees have prospered so astonishingly, and the timber produced from such as have been cut down, has so fully answered all the eulogiums that have been bestowed on it, that the larch is now considered on the whole, as decidedly the most valuable timber-tree, not even excepting the oak. Some of the first-planted larches in the low grounds, near Dunkeld, have grown to the height of one hundred and twenty feet in fifty years, which gives an average of two feet four and a quarter inches a-year. It is stated by the Duke of Atholl, in a communication to the Horticultural Society, made in June, 1820, that on mountainous tracts, at an elevation of fifteen or sixteen hundred feet, the larch, at eighty years of age, has arrived at a size to produce six loads (300 cubic feet) of timber, appearing in durability and every other quality, to be likely to answer every purpose, both by sea and land. (Hort. Trans. iv. 416.) Professor Martyn (Miller's Dict. in loco) has brought together a mass of valuable information respecting the history of the larch in this country, and its uses in others. That singularly accomplished agricultural writer, Dr. Anderson, did much to promote its increase by his essays and other works from 1750 to 1790; and subsequently the Bishop of Llandaff, Marshall, Nicol, Pontey, and Sang, have each, in practice, and by their popular publications, contributed to spread the tree; and now several millions are annually planted in the mountainous districts of the empire. The larch, Sang observes, passes all other timber-trees, for the first ten or twenty years after planting, and will arrive at a timber size in almost any situation or soil. It bears, he says, "the ascendency over the Scots pine in the following important circumstances: that it brings double the price, at least, per measurable foot; that it will arrive at a useful timber size in one half or a third part of the time, in general, which the fir requires; and, above all, that the timber of the larch, at thirty or forty years old, when placed in soil and climate adapted to the production of perfect timber, is in every respect superior in quality to that of the fir at a hundred years old. In short, it is probable that the larch will supersede the Scots pine in most situations in this island, at no very distant period." The finest specimens of this tree are at Dunkeld, Blair, and Monzie, in Perthshire.

7064. Use. Much has been said of the durability of larch-timber in Italy: its resistance to fire, according to some (Matthiolius), and its great combustibility, according to others (Du Hamel); its durability under water (at Venice), and its not being liable to warp (Harte). We shall confine ourselves to its uses as experimentally proved in Britain; and perhaps we shall do this with most effect by stating that it may be used for all the purposes for which the best foreign deal is applied; for many of those of the oak; and that it is more durable than any other timber when placed in a situation between wet and dry, especially if the bark be not removed, it being still more incorruptible than the wood. The bark is also of considerable value in tanning; a circumstance of great importance, since it is found that disinfecting a year or more previous to felling is the best mode of seasoning the timber (565.), and preventing it from warping, or being attacked by the dry or wet rot. (5927. and 6894.) One property almost peculiar to the larch is, that the timber is exceedingly valuable at every period of its growth; so that a dead hedge of larch-branches, or a hurdle wattle with larch-spray, will last as long as hedges or rails of any other species of timber. Placed in the open in exposed gardens it forms a useful hedge plant in point of shelter; but in this respect is deficient as a fence, and gets soon naked below. Rods, stakes, palis, rails, posts, and especially gate-posts, of this tree, are therefore more valuable than of any other; the sparse fit approaching the nearest to it in these respects. Turpentine is extracted from it in the Tyrol; but that being always injurious to the timber, can never be recommended for adoption in this country: it is also peculiarly valuable as a nursing-tree.

7055. Variety or species. Of the *P. larix*, there is a variety with red and another with white flowers, one with cincinnous bark, called the Russian larch, and one with pendulous branches. There are also the
black larch (P. pendula) and red larch (P. microcarpa), natives of America, by some considered distinct species; the timber of both of which is said to be harder than that of the common white larch. As these trees grow with the species trees, they are the varieties which are succeeded by being planted as timber-trees. There are, however, a few large specimens at Dunkeld and other places; and from these the trees will probably soon be propagated by seed, and a practical estimate be formed of their value. Some spars from some trees of wood are said at Dunkeld to be nearly as hard as the old third as many cubic feet of timber as the white larch at the same age. The wood is so ponderous that it will scarcely swim on water. (Hort. Trans. iv. 416.)

7056. Soil and site. The larch will grow and attain a large size in every soil and situation, excepting in standing water; but a certain elevation of surface, or coldness of climate and inferiority of soil, is absolutely necessary to produce the timber in perfection. The quality of the timber of all trees is more or less affected by climate and soil; but that of the resinosum tribe particularly so. We pointed out several instances in 1856. (Treatise on Country Residences, ii.) Sang mentions a number as having occurred since 1819 (Pamph, Lumbermen, 1824), and he has observed that a small larch will grow and increase in progress for 30 or 55 years, and though there was no external signs of disorder, yet, when it was felled, the wood had begun to rot in the hearts of the trees; so that there was scarcely a sound tree over a large extent of ground. Here, therefore, the idea of the chestnut, that had been used as a nurse, are not only in the utmost vigor, but their wood is perfectly sound. Some larches in a similar soil and situation had attained seven feet each, and were quite hollow a good way upwards.

7057. Insects. The Coccus laricis, and the others mentioned as inhabiting the common pine.

7058. The Norway fir, or common spruce fir, (P. Abies, L. (Lam. pin. 73. t. 25.) Sapin, Fr.; Fichte, or Tanne, Ger.; Abete, Itali.) is the first species of that section of pine in which the leaves are solitary. It is one of the tallest of European trees, attains from 100 to 150 feet in height but not thick trunk, and throwing out its spreading frond-like branches so as to form an elegant narrow cone of vivid green. It is a native of the north of Europe, and particularly abundant, as the name imports, in Norway: its timber being the white deal received from that country and the Baltic.

7059. Use. The timber is inferior to that of the common pine in durability and bulk; and being often knotty, is not proportionally strong for horizontal bearings with that timber. White Norway deal, however, is used for a great variety of purposes in building; and the entire trees are more prized than any other for masts for small crafts, for spars both for marine purposes and on land. What constitutes the value of this fir is, that its timber is equally durable at any age, like that of the larch; and what renders it peculiarly adapted for masts, spars, scaffolding, poles, &c. is its habit of almost in every case, whether standing single or detached, growing perfectly erect and straight. The tree may be cut for rods, staves, and spars, and the felling of the trunk will be found between the two inches in diameter, and the bark being kept on it, it will prove almost as durable as the larch. Pontey says, that poles of spruce are so far inferior to those of the larch, that they are more apt to crack when exposed whole to the influence of the sun and air; but in all other respects it is nearly equal to it, and in straightness the best passes it. The tree is peculiarly valuable as a nurse, from being evergreen, and closely covered with branches, by which radiating heat is retained; from its conical shape and rigid stem, by which it does not succocate or whip the adjoining trees; from its being valuable at whatever age it is thinned out; and from its being an excellent shelter for the most valuable game. It will not, however, grow in situations where the common pine and larch will flourish. It is also an excellent hedge plant for shelter, but is deficient in point of defence and berth. By incision, it yields a resin, from which, by various preparations, turpentine and Burgundy pitch are formed. The tops or sprouts (sprouten, Ger.) give the flavor to white and red spruce beer.

7060. Varieties and species. Linnæus has five varieties of P. abies; but the principal are, the white (P. alba) (Lam. pin. 39. t. 26.), the red (P. rubra) (Lam. pin. 43. t. 38.), and the black (P. nigra). (Lam. pin. 43. t. 39.). All native in America, and the white, it is said, possesses nearly the same properties as that of the European species. The white spruce rises only to 40 or 45 feet, with pale bluish-green leaves. The black spruce is reckoned the most durable of the tribe. In America, the black spruce is used for knives in ship-building, where neither oak nor black larch can be easily obtained; these knives are not prepared from two diverging branches, as in the oak; but from a portion of the base of the trunk connected with one of the largest diverging roots. The timber of the red is universally preferred throughout the United States for sail-yards, and indeed imported for this purpose into Liverpool from Nova Scotia, where it is also manufactured. It is chiefly from the decocation in water of young shoots of the black, and not exclusively from those of the white spruce, as supposed by Lambert, that the celebrated beer is prepared by fermentation, with a due proportion of sugar or molasses. The essence of spruce of the dealers is prepared by evaporating this decocation to the consistence of honey.

7061. Soil and site. Pontey says it grows rapidly on every description of soil, from a very stift loam, and possessing such a very considerable degree of humidity, to a very dry sand, provided the situation be not very much exposed. Sang says it luxuriates much in deep low situations: in shallow soils and exposed situations, it is not raised. It is also stated of the larch, that it is never be found on higher ground than 20 feet above the sea, or on any groves or groves by itself; otherwise its timber is so coarse and knotty, that it is hardly worth working: but in the mass way, if planted thick, and properly pruned and thinned afterwards, it may be trained to tall clean timber tree.

7062. Insects. The Coccus abietis, and occasionally the others which infest the common pine.

7063. The silver fir (P. Picea) (Lam. pin. 46-t. 30.) (fig. 671. a) is a lofty evergreen tree, forming a cone broader at the base, in proportion to its height, than the spruce, and displaying a more stable and majestic figure than any of the other firs. It is more thinly covered with frond-like branches than the spruce, and differs from it also in regard to the frondlets, which, when they grow old, and begin to decay, do not drop down as in that tree, but remain rigid till the last. The upper surface of the leaves is of a fine vivid green, and their under surface has two white lines running lengthwise on each side of the midrib, giving the leaves that silvery look, whence has arisen the name. It flowers in May, and the cones are ripe in December. It is a native of the Alps and Germany, was known here in 1603, and has been a good deal planted
as an ornamental tree. It grows faster for the first twenty or thirty years of its growth than any other tree of the genus, excepting the larch. Some of the finest specimens in England are at Woburn, in the evergreen-drive, planted by Miller. The tree called the grand silver fir there, measured, in 1810, nine feet ten inches in diameter, at four feet from the ground; it has a clean-pruned stem of seventy-five feet, and the estimated height is upwards of 110 feet.

7064. Use. The timber is reckoned inferior to that of the common pine, and is not of much value till of forty or fifty years’ growth. According to Sang, though till of late years planted only as an ornamental tree, “yet there is, perhaps, none of the genus more worthy of cultivation for the sake of its timber.” It is more prolific in resinous matter than any of the fir kind.

7065. Its soil and site are nearly similar to those most desirable for the common spruce; but it requires a climate rather milder, and a more loamy earth. On poor sands, where the common pine and larch will thrive, it dies off in a year or two after planting. None of the genus are more majestic on a lawn; but its characteristic or natural situation, is in dells, and on the sides of sheltered rocky steeps.

7066. The balm of Gilead fir (P. Balsamea) (Lam. pin. 48. t. 31.) (fig. 671. b) is an American tree of much smaller stature, and more delicate habits than the silver fir. Its timber is of little value; nor can the tree be reckoned very ornamental, though frequently planted for the sake of variety. The balm or resin procured from it possesses no medical properties superior to those of common turpentine; but the tree during summer sends out a pleasing terebinthinate odor.

7067. The hemlock-spruce, or hemlock-fir (P. Canadensis) (Lam. pin. 50. t. 32.) (fig. 671. c) is a drooping, low, evergreen tree, which may be considered as entirely ornamental.

**Sect. II. Hard-wooded non-resinous Trees.**

7068. Of hard-wooded trees we shall give a few descriptive traits of the principal species; the most important of which are the oak, ash, elm, chestnut, and beech.

7069. The oak is the Quercus, L. *Monaco, Polyan. L. and Amentaceae, J. Chêne, Fr.; Eich, Ger.; and Quercis, Ital. The following species and varieties are planted for their timber.

7070. The common oak (Q. robur) (Eng. Bot. 1815.) is a native of Britain. It grows to the height of fifty or sixty feet when in a heavy loam; flowers in April, and ripens its acorns in October and November. The most valuable variety of the common oak is said (Colcut. Hort. Mem. iii. 576.) to be the pedunculata (Eng. Bot. 1340.), or the stalk-fruit ed; by some considered a distinct species. It is distinguished from Q. robur by the acorns being placed on long fruit-stalks, while those of the robur are nearly sessile. Besides, the superior utility and hardness of the timber, the pedunculata is, in fact, the more magnificent of the two British sorts. Miller says, this variety of the Q. robur (and which he calls the *femina*) is more rare than the sessile-fruit ed; but Professor Martyn says, this is not the case, as the *femina* is equally general as the other. It is observed by Du Hamel, that oaks in forests being propagated from the acorn, there are so many varieties that it is difficult to find two resembling each other in every respect. Professor Martyn observes, that the figures in ancient authors have the fruit uniformly on foot-stalks, which shows that that variety had been most common; and Hay considers it as the common oak of England. Du Roi affirms, that the timber of the sessile-fruit ed is reddish, and brittle, whilst that of the stalk-fruit ed is whitish and hard. From these and various accounts, as well as our own observation, we consider ourselves justified in recommending to nurserymen and others, who gather acorns for seeds, to take effectual precautions that only the stalked sort be gathered.

7071. The Turkey oak (Q. cerris) (Du Rol. 2. t. 5. f. 1.), a native of the south of Europe, introduced in 1735. This species is distinguished by oblong, pointed, and frequently lyrate leaves, jagged, and a little hoary on the under side. The acorns are small, and have rough prickly cups. The tree grows from forty to sixty feet high. There are several varieties, but the best is that called the Devonshire or Lucamebe, from the name of the person who raised it from seeds, saved from a tree of the Turkey oak grown in Devonshire.

7072. Other oaks. There are about forty species of exotic oaks introduced in this country, which may be considered as timber-trees, and are such in effect, in their native countries. Of these the greater part are hard and tough, and have been recommended (Colcut. Mem. iii. 575.) to cultivate the Q. tinctoria or Quercitrin on account of its bark, which affords a valuable yellow dye; all these species, however, are either too tender, or too scarce, or too dwarfish, and slow-growing, to warrant us in considering any other than the common and Lucamebe oaks, as fit for the purposes of profitable planting.

7073. Use. The oak cannot be considered so valuable a tree for general purposes as the common pine and larch; but its great strength and durability will probably long maintain its superiority in Europe, and the other temperate regions of the globe, as a material for naval architecture. The timber is useful at every age, and more durable when of small diameter than that of any other of the hard woods; the value of the bark of young trees is greater than that of such as are old.

7074. Soil and site. It grows best in a deep clayey loam, not beyond a moderate elevation above the sea; but it will grow in any soil not marshy, not retaining, however, a large size in poor sands or at a considerable elevation.
PRACTICE

7071. The common ash (F. excelsior, L.) (Eng. Bot. 1692.) is a native of Britain, and grows from sixty to eighty feet in height, with a straight stem. It has pinnate leaves, which come out late in spring, generally from April 22nd to May the 10th, and fall early in autumn; they are round and heart-shaped, with seven or eight leaflets in the set, and are alternatively arranged on the stem. The small nut (Cynips quercus folii, L. Diplapris, L.) (fig. 675.) pierces the leaves with its sting, and deposits its eggs in the wound; the extruded juices rise round it, and form a gall, which becomes hard, and in this the larva lives and feeds, and changes to a pupa. The oak-gall commerce is so formed; the best are imported from Turkey and Greece.

7072. The ash is the Fraxinus, L. Polygam. Drax. L. and Octrine, B. F. Drax, Fr.; Aech, Ger.; and Frasino, Ital. There are two species which may be considered as forest trees.

7073. In England the elm is the Ulmus, L. Pentand. Dig. L. and Amentaceae, J. Orme, Fr.; Ulmebaum, Ger.; and Olma, Ital. There are two species which may be regarded as timber-trees.

7074. The English or narrow-leaved elm, U. Campestris. (Eng. Bot. 1886.) (fig. 674 & c) It is considered a native, or naturalised in England, by Sir J.E. Smith and others; but Dr. Walker considers it as brought originally from the Holy Land. It would be difficult to point out any situation where it has the appearance of having sprung up from seeds; though it is said to be common in the woods of the north-west of England. It is certainly the tallest of the deciduous trees of this country, being often forty yards or upwards of eighty feet high. It develops from April to May, and ripens its seed in a fortnight or three weeks after the decay of the flower. This species requires a well-drained soil, or rather a good loam, and a moderately open situation, and is also a native of Germany. It does not thrive in the north of England, or in Scotland, unless in good soils and moderately sheltered places. Professor Martyn says, it is not found north of Newark on Trent. It grows to a great size in Ireland, and is the tallest of those, and yet one of the slowest growing, of all the trees of Ireland. The biggest elm in England is Piff's elm, near the Bathington oak. At five feet it is 116 feet high; at ten feet it throws out large arms, which rise seventy or eighty feet. Some of the elms in the valley of the Black Mountains of 500 years old. Boucher says, that he sold a line of English elms, about sixty in number, which at twenty-four years' growth were about eighteen inches in diameter, a foot above ground, and forty feet high.

7075. The Scotch or smooth-barked elm (U. glabra) (E. B. 2245.) (fig. 674 & b) is readily distinguished by its smooth, polished bark, and by its leaves, which are nearly smooth on the upper surface. It is the most useful timber-tree of the genus, and is about the only tree of the elm kind planted in Scotland, where it also forms stocks for grafting the Dutch and English elm. A new variety of this species has attracted notice at Dowant, which Selby (Hort. Trans. vi. 146.) proposes calling the Dowant elm. A very elegant cabinet variety, called the Scampston elm, is in vogue in Durham and Northumberland.

7076. Other species. The genus ulmus, like salix, is one of those whose species are so nearly related as to be often confounded. Linnaeus divided all the Ulmaceae into seven, and the Linnaeanists make five British species, besides an equal number from America. The U. campestris and glabra, however, are the only sorts worth cultimating for their timber. (Dow, in Hort. Tour, 539.)

7077. Use. Elm-timber is used in all works where it may be continually dry or wet; as, for water-pipes, pumps, etc.

7078. Soil and site. The narrow-leaved elm requires a light dry soil and warm situation, and will do well in sandy or gravelly soil, in exposed places; but the smooth-barked sort is a very hardy tree, and will grow in thin clayey soil on retentive substrata better than most others. It will also thrive in situations elevated and exposed on all sides.
7088. The beech is the Fagus sylvatica, L. (Eng. Bot. 1846.) Monoc. Polyn. L. and Amentaceae, J. Héter., Fr.; Büche, Ger; and Faggio, Ital. It is a native of England, and grows in its natural soil and situation to sixty or eighty feet high. It is found congregated in forests, in chalky flinty soils, thrives well in sheltered bottoms: but not where it is exposed to the west. There are fine specimens of this tree at Castle Howard, Woburn, Newbottle, and Dalkeith Park. It is not so long-lived as the elm, nor will it grow in situations so much elevated as will the Scotch elms.

7089. Use. The timber is brittle, and decays soon in the air; but under water it is more durable. It is used by the millwright, turner, carver, last and wheel maker, chair and cabinet maker, and more or less in other branches. It is much used by bakers and in glass-houses as billet-wood; and the stack-wood forms an excellent charcoal.

7090. Soil and site. Dryness and some degree of calcareous matter are the characteristics of the soil in which the beech delights; and the declivities of hills facing the east or south are its favorite situations.

7091. The common hornbeam is the Carpinus Betulus, L. (Eng. Bot. 2032.) Monoc. Polyn. L. and Amentaceae. It is a native tree, nearly allied in habits and appearance to the beech, but is less lofty, and thrives in colder stiffer soils, and in rather more elevated situations. It flowers in April, and ripens its seeds in November. "Although Evelyn is perhaps too partial to the hornbeam, yet, raised from seed, it forms a tree of the first rate, equaling the common beech in magnificence; but unfortunately the hornbeam, like several of our best forest trees, may with ease, almost at any period of the year, be propagated from layers, and the usual consequences of this practice, follow,—a stinted, bushy, dwarf-like progeny. This tree, however, retaining its decayed, shrivelled, pale-russet leaves during winter, like the common beech, forms most valuable shelter planted in hedges." (Cal. Mem. ii. 397.)

7092. Use. Chiefly in turnery, being white and tough as the name imports. It is frequently used as a substitute for the beech.

7093. Soil and situation. A dry soil is essential, whether cold or chalky. It is a social tree, and found in natural coope-woods, as in Hertfordshire; but never at any great height above the level of the sea.

7094. The Spanish chestnut is the Castanea vesu, W.; Fagus Castanea, L. (Eng. Bot. 886.) Monoc. Polyn. L. and Amentaceae. It is the Châtaignier of the French; Castanienbaum of the Germans; and Castagno of the Italians. It is one of the most magnificent of European trees, exceeding the oak in height, and equalling it in bulk and extent. It is doubtful whether it be a native of Britain, though it ripens its fruit in sheltered valleys even in Scotland. It seems a very long-lived tree, of which the best proof is the specimen on Mount Etna, two hundred and four feet in circumference. Boucher says, the shade of the chestnut, like that of the ash, is injurious to other plants. The leaves which continue late in autumn are not liable to be eaten by insects like those of the oak. The Spanish chestnut has been already described as a fruit-tree. (4745.) As a timber-tree it is used for the same purposes as the oak; though by some considered as more brittle when old. The roof of Westminster Abbey, and that of the Parliament House in Edinburgh, with many other antient works, are said to be constructed of it; but considering that it is not a native tree, this is extremely improbable; and it is much more rational to suppose, with Professor Martyn and Daines Barrington, that what is by many taken for chestnut, is only oak of a different grain. It is used by the cabinet-maker and cooper; makes an excellent coppice-tree for poles and hoops; the bark is equal in astringency to that of the larch and mountain-ash for tanning; and the leaves and nuts afford food both for men and deer.

7095. Soil and situation. The soil in which it thrives best is a deep sandy loam, and the situation one somewhat sheltered. In Calabria, and on the Apennines between Florence and Bologna, where we have seen it in abundance, it does not attain a great size on the higher and more exposed parts of those mountains, but it, as Sang observes, a surprisingly magnificent tree in the hollows. Pontey says, "on sandy soils, where the oak would make but slow progress, I have seen the chestnut grow extremely quick, and therefore, in such cases, the latter should be used instead of the former."

7096. The oaknut (Juglans regia) has been already treated of as a fruit-tree. (473.) Its timber, when of mature age, is valuable as a cabinet wood, and for gun-stocks, being light, hard, and durable.

7097. The common sycamore is the Acer Pseudo-platanus, L. (Eng. Bot. 303.) Polyg. Monoc. L. and Aceraceae. J. It is one of our hardiest native trees, and equal in magnitude with, though more tame in its outline and form than, the oak. It flowers in April and May, and ripens its keys or seeds in November. Its foliage is earlier than that of most trees, and its decadence is next to that of the ash. It is a quick grower, will endure the sea-breeze better than most trees, and is not liable to grow to one side when exposed to winds that blow chiefly in one direction.

7098. Use. The timber is chiefly used by the turner and millwright, and formerly, when earthenware was less common, it was in great request for treenchers and other table and household utensils. It affords a saccharine juice, like the sugar and other American maples, from which a wine may be made.

7099. The Norway maple (A. platanoides) is a tree common in the native woods of Lithuania; and in Norway it clothes the hills from the sea-shore to their summits. It grows to a large size, and its leaves die to a golden color. Its timber does not differ materially from that of the sycamore.
PRACTICE OF GARDENING. Part III.

7100. Soil and situation. Both thrive best in a soil similar to that preferred by the ash, but will grow in all inferior soils, and exposed to the sea-breeze as well as at a great height above the level of the sea.

7101. The mountain ash is the *Pirus aucuparia*, E. B. (*Eng. Bot.* 337.) *Icos.* *Di-Pentag.* L. and *Rosaceae*, J. It is a low and very hardy native tree, attaining the height of twenty or thirty feet, with a straight, clean, erect stem, and globular compact head. It flowers abundantly in April and May, and ripens its berries in August or October, according to the situation.

7102. Use. In profitable planting it is chiefly valuable as a nurse-tree, growing very fast when young, and enduring the most severe exposures. The timber is used by wheelwrights, and for other common country purposes; the bark is used by tanners; and the berries afford a dye. As an undergrowth it affords tolerable poles and hoops.

7103. Soil and site. It will grow in any soil, dry or wet; and as to situation, it is found on the seashore, and near the tops of the highest mountains. It seems to thrive best on the sides of most rocky depressions.

7104. The whitebeam-tree (*Pirus aria*) (*Eng. Bot.* 1858.) is a very hardy native tree, growing to the height of thirty or forty feet, with an erect stem. Its uses and culture are the same as those of the mountain-ash. Its white leaves, and coral berries mealy to the taste like those of *Pirus terminalis* (4768.), have a fine effect in autumn.

7105. The acacia, or locust-tree. — *Robinia pseud-acacia*, L. (Schmidt, Arb. t. 39.) *Diadelph. Decan.* L., and *Leguminosa*, J. This is a thorny fast-growing tree, of middling stature, a native of America, of no great beauty as a tree, but ornamental when young, and very well adapted for coppice-wood and rough timber. It flowers in June and July, and ripens its seeds in September. The leaves come out late in spring, and fall early in autumn like those of the ash.

7106. Use. The timber is much valued in North America, and said to be superior to that of the laburnum. It is used by cabinet-makers, and in America more valued by the cabinet-maker than any other native timber whatever. Pursh, in his late valuable *Flora*, asserts, that being nearly incorruptible, it is equally useful for posts and gates. We are informed by a friend, that gate-posts of this timber, on a property near Baltimore, have remained fresh for nearly a century. The finely pine-yelled leaves, and white fragrant flowers, add greatly to its beauty. Its value is scarcely known in this country.” (Caled. Mem. ll. 414.)

7107. Soil and site. It prefers a deep sandy soil, and rather sheltered situation; being very apt to throw up long white running roots, and as it stolons freely, it seems peculiarly calculated for coppice-woods. Beaton (Com. to Board of Agr.) has cultivated it in this way to great advantage.

7108. The birch is the *Betula*, L. *Monac. Poly.* L. and *Amentaceae*, J. *Bouleau*, Fr.; *Birchenbaum*, Ger.; and *Betulla*, Ital. There are two species which may be considered valuable as timber-trees. The common birch (*B. alba*, var. *pendula*) (*Eng. Bot.* 2198.) is a middle-sized native-forest tree, distinguished by its white bark, fragrant leaves, and graceful pensile form. It grows in the coldest regions of the north, and farther up the sides of the British mountains than any other timber-tree. In the swampy grounds of Sweden and Russia it grows to a much greater size than in the more temperate climate of this country. It is of importance to cultivate the pendulous variety as a taller and more rapid-growing tree independently of its variety.

7109. The American birch, mahogany-birch, mountain mahogany, or cherry-birch of Canada, is the *B. leuta*. (Mich. Arb. 2 p. 145. t. 4.) (fig. 675.) This is a more lofty tree than the common birch, with a brown-colored bark spotted with white. It abounds most in the middle states of Pennsylvania, New York, and the Jerseys, where it attains a height of seventy feet; but disappears altogether in the higher latitudes of the northern states, and is scarcely to be found in Nova Scotia. It is therefore likely to succeed with us in the moist and deeper soils of our Highland valleys, especially when closely associated with other trees. The probability of this is heightened by various facts already ascertained. The value of the timber is well known to our cabinet-makers; and we have seen tables, bed-posts, and other articles of furniture made of it, equaling in beauty those of mahogany, which it resembles, when some time exposed to the light, the newly wrought boards being of a rose-color. Although of an exceeding quick growth, the grain being naturally close, it takes a fine polish in cabinet-work. We add to this, that the leaves, which appear early in spring, are said to possess a peculiar fragrance, which they retain when dried by means of a stove, affording, on infusion of boiling water, an agreeable diurnal, superior to some of the common teas of commerce.” (Caled. Mem. ll. 380.)

7110. The poplar-leaved birch (*B. populifolia*) (fig. 675 a) and *Hudson's birch* (*P. Hudsonii*) (fig. 676 b) are elegant rapid-growing trees, and when once they are soar and cultivated, will deserve culture as timber-trees.

7111. Use. The timber of the common birch in England is chiefly used as fence-wood, fuel, and occasionally for harrows, &c. and other agricultural implements, the tree being most frequently planted as a nursery tree, either for commerce or variety. This tree, like the mountain ash, will grow in almost every kind of soil and situation.

7112. The wild cherry is the *Prunus avium*, L. (*Blackw. t. 425.*) *Icos.* *Di-Pentag.* L. and *Rosaceae*, J. *Guigne*, Fr.; *Wild Kirschen*, Ger.; and *Ciriegio Silitatia*, Ital. It is a native tree above the middle size, the timber of which is of considerable value. It thrives best in dry sandy loams; and in such situations, Sang observes, its timber becomes of most value. It is of peculiar beauty in spring when in flower, in August
when in fruit, and in autumn when its leaves change to a beautiful red and yellow. Its timber is chiefly used by the cabinet-maker and chair-maker.

7113. The tree-laburnum. — *Cytisus alpinus*, W. en. (Bot. Mag. 176.) Diadalphi. Decan. L., and *Leguminosae*, J. It is a low tree, a native of Switzerland, cultivated chiefly for ornament, but affording also a valuable timber. For this purpose the variety or species (*C. alpinus*), with broad leaves and long racemes, is decidedly to be preferred, as being much more of a tree than the other. Sang says, it has a full claim to the characters of useful and ornamental; is beautiful when in flower, and may, in a grove, be trained to a fine stem of very considerable size.

7114. Use. The timber (the false ebony of the French) is much prized by cabinet-makers and turners, for its hardness, beauty of grain, and durability. The tree is frequently sown in plantations infested with hares and rabbits, who will touch no other tree as long as a twig of laburnum remains. "Though eaten to the ground in winter," as Boucher observes, "it will spring again next season, and thus afford a constant supply for these animals, so as to save the other trees till of a size to resist their attacks. The timber has been sold for upwards of half a sovereign per foot." It becomes most valuable in light loams and sandy soils.

7115. The holly is the *Ilex aquifolium*, L. (Eng. Bot. 496.) Pent. Monog. L. and *Rhamni*, J. *Houx*, Fr.; *Steckbaum*, Ger.; *Agrifoglio*, Ital. It is an elegant, shining, evergreen tree, rising from twenty to thirty feet high, affording a timber of considerable value, and much in use as an ornamental hedge plant. It is a native of Britain, of great longevity, and found growing in woods and forests, as an undergrowth to the oak, beech, ash, and fir. It thrives best in a free deep loam, rather light, as in Needwood Forest, in Staffordshire, and the fir-forest of Blackhall, near Aberdeen. It is a cheerful-looking tree from its shining leaves and coral berries, and peculiarly fit for ornament.

7116. Use. The timber, which is as white as ivory, is chiefly used in inlaying and veneering, and by turners and mathematical-instrument-makers. The straight shoots, of five and six feet in length, make excellent coachmen’s whips. Birdlime is made from the bark by washing and separation of the woody fibre. Sheep and deer eat the cropings. It is the best of all hedge plants. It thrives best in cold loamy soils, and rather sheltered situations.

7117. The hazel (*Corylus avellana*), already treated of as a fruit-shrub (4752.), forms a hardy useful undergrowth in most situations, supplying hoops, crate-ware, basket-stuff, walking-sticks, rods, poles, witties, fence-wood, fuel, &c.; besides the fruit, where the soil is tolerable, is worth something, and an excellent charcoal is made from the stack-wood.

7118. The box-tree (*Buxus sempervirens*, L. (Eng. Bot. 1941.) Monoc. Tetran. L. and *Euphorbiaceae*, J. *Buia*, Fr.; *Buckbaum*, Ger.; and *Bosolo*, Ital.) has some claims to attention as a valuable timber, being in considerable demand for inlaying, turnery, mathematical instruments, and wood-engravers’ blocks. It thrives in any light soil and under the drip of trees. Raised from the seed it will attain the height of twenty or twenty-five feet, and be fit to cut down in thirty years. (Miller’s Diet. in loco.) As an ornamental undergrowth and edging plant, it is of the greatest value.

7119. The elder-tree (*Sambucus nigra*), already treated of as a fruit-tree (4627.), forms an excellent nurse-plant in exposed situations, and a rapid hedge in most places. The wood is very hard, and used by the toy-makers and turners. When grown as a nurse, or for timber, it should always be raised from the seed.

7120. The hawthorn.— *Mespilus oxyacantha*, E. B. (Eng. Bot. c. ic.) Icos. Di-Pentag. L. and *Rosaceae*, J. *Aubépine*, Fr.; *Hagedorn*, Ger.; *Branco spinos*, Ital. It is a native shrub, of great importance as a hedge plant, and is also frequently introduced into narrow plantations as an undergrowth. It will not grow, however, under the drip of trees, and therefore, in a profitable point of view, is only to be considered as affording the impermeable, close, durable, and easily raised fences, called quickset-hedges. The timber of such plants as grow singly, and attain a tolerable size, is valued by the millwright and turner, and the roots by the cabinet-maker. It is often spoiled, Sang observes, through inattention after cutting; if it be allowed to lie in entire logs or trunks, it soon heats, and becomes quite brittle and worthless; it therefore ought to be instantly cut up into planks, and laid to dry. The haws and foliage afford excellent food for deer.

7121. Soil and site. It will not thrive in a wet soil, nor one very dry and poor, much elevated or much shaded; a free deep loam in an airy situation suits it best. For hedges it may be raised from cuttings of the roots, planted where they are finally to remain. Such cuttings are only to be procured in quantities
PRACTICE

where an old hedge is to be removed, and the labor of selecting and preparing them falls little short of the price of good two-year seedling plants; so that unless in a season when thorn-plants are scarce and dear, few advantages attend this practice.

7122. The yew is the Taxus baccata, L. (Eng. Bot. 746.) Polyg. Monoc. L. and Conifere, J. Iff Fr.; Ehenbaum, Ger.; and Tasso, Ital. It is a low, bush-like, dark, evergreen tree, of great longevity, slow in growth, and affording a hard, white, valuable timber. It flowers in April and May, and its berries are ripe in November. It is found in a wild state in bleak situations, and on a variety of soils, dry and moist. It is very common in ancient churchyards, in many of which it has attained a great size and age. Evelyn, and after him, Professor Martyn, have referred to a great number of examples of notable trees of this species.

7123. Use. The timber is used by the cabinet-maker for inlaying, and by the mathematical-instrument-maker, and whipmaker. It is sometimes used as a substitute for box and other hard woods, and every one knows it was formerly used for bows, and the spray as palm-leaves by the ancient Christians. It forms one of the best hedge plants for gardens, topiary work, &c. and for this purpose was much employed when the geometric style of gardening prevailed.

7124. Soil and situation. Almost any soil, not over-wet, will suit the yew, and it will grow on the bleak sides of mountains, and under the drip of trees.

Sect. III. Soft-wooded Trees.

7125. The soft-wooded timber-trees may be considered as characterised by great rapidity of growth, comparatively limited duration, and timber of inferior value.

7126. The horse-chestnut (Aesculus hippocastanum, L. (Schmidt, arb. 1. t. 38.) Hop-tand. Mong. L. and Acerace, J. Marronier, Fr.; Marronienbaum, Ger.; and Marrone, Ital.) is a magnificent and beautiful tree, when in May it is covered with its digitate foliage, and fine large spikes of white flowers. It is of rapid growth, and speedily produces a considerable bulk of timber, which, however, is of no great value. Being highly ornamental as a single tree, and in the outskirts of plantations, it need never be planted in masses for timber. It was brought from the northern parts of Asia into Europe, about the year 1590, and was cultivated by Gerrard and Tradescant. As Gilpin observes, it is far from being a picturesque tree, its outline being that of a parabola: but all beauty is not picturesque beauty, and the foliage and flowers will ever advocate the cause of this tree, (which the Hon. D. Barrington compares to a giant's nosegay,) though "its leaves begin to drop early in summer, and make a litter around the trees during the remainder of the season."

7127. Soil and situation. It requires a good, rather dry soil, and suffers materially from storms of every kind when planted in exposed situations. It used formerly to be much used as an avenue tree, especially by the French, and is particularly adapted for this purpose, and the margins of plantations.

7128. The lime. — Tilia Europeae, L. (Eng. Bot. 610.) Polyand. Monog. L. and Tiliacee, J. Tilleul, Fr.; Lindenbaum, Ger.; and Tiglio, Ital. This is one of the most beautiful, graceful, and fragrant of our native trees, rising to the height of seventy or eighty feet, and finely clothed with pendulous recurved branches, from the ground or the browsing line formed by cattle upwards. It is found wild in woods and grassy declivities, sends out its leaves in April, flowers in May, and ripens its seeds, though sparingly, unless under favorable circumstances, in October.

7129. Use. It was much valued by the Romans for its shade, and the multiplicity of purposes to which the timber was applied. It is now more a tree of ornament than of profit, but the timber is still used for various common purposes in general economy, and by the carver, turner, and musical-instrument-maker. It forms an excellent charcoal for gunpowder; and of its inner bark, macerated in water, is formed, in the north of Europe, the base mats of commerce. This bark is called in Sweden and Russia, bast, whence, by corruption, bass. It is the finest of all trees for avenues, and forms good tree-hedges. The famous Kowno honey is made exclusively from the blossom of this tree.

7130. Varieties and species. There are several sorts noticed in our Encyclopaedia of Plants, but the best, both for effect and timber, is the red-twigged (T. Eu. var. corallina), and the broad-leaved American (T. Americana), which is a distinct species, distinguished by the larger size of the leaves, and elegant pendulous flowers.

7131. Soil and situation. All the sorts prefer a deep loam, and rather sheltered situation, for though patient of cold, they are much injured by storms. In Sweden, the common species abounds among the debris of granite and trap rocks; and in Russia it covers extensive tracts of deep, soft, black earth. In bleak situations, where it is not covered by snow in winter at the roots, or sheltered by other trees, it will not thrive.

7132. The alder (Alnus glutinosa, W. (Eng. Bot. 1505.) Monoc. Tetrand. L. and Amentaceae, J.) is a middle-sized native aquatic tree of no great value, either as timber or ornament farther than that it will grow where few other trees will thrive, excepting the birch, poplar, and willow. It flowers in May, and ripens its seeds in September and October.

7133. Use. The timber is used in water-works, and by the turner, millwright, last-makers, and others, as well as for common country purposes, and charcoal.

7134. The poplar. — Populus, W. Dizec. Dodec. L. and Amentaceae, J. Peuplier, Fr.; Poppelbaum, Ger.; and Poppio, Ital. There are several species which may be reckoned timber-trees.
The variety called the common poplar is distinguished from the common wild poplar by its larger three, four, or five lobed leaves, dark above and downy under, and by the young shoots having a purple bark covered with white bloom. It is a rapid-growing tree, speedily attaining great bulk of timber, a height of 60 or 70 feet, and great extent of branches. The V. pustulosa seems a variety of this tree; and on the banks of the Vistula, particularly at Villeneuve, near Warsaw, grows to upwards of 100 feet high, with a clean trunk and ample head.

The common black poplar (V. nigra) is a native tree, of lofty growth, distinguished by its dark-green leaves, lightly notched on the edges, and ash-colored bark. It is, by some, considered a mere variety of the alba, and for the purposes of profit may be so considered.

The trembling poplar (V. tremula) grows to a lofty tree, occupies little space, and is not so injurious by its shade. It will not thrive, however, in exposed situations, or in very indifferent soils. Some of the largest trees of this species are at Blenheim. Sang and Nicol say it seldom thrives in Scotland.

The black Italian poplar (V. diltata) grows to a lofty tree, occupies little space, and is not so injurious by its shade. It will not thrive, however, in exposed situations, or in very indifferent soils. Some of the largest trees of this species are at Blenheim. Sang and Nicol say it seldom thrives in Scotland.

The Lombardy poplar (V. diltata) grows to a lofty tree, occupies little space, and is not so injurious by its shade. It will not thrive, however, in exposed situations, or in very indifferent soils. Some of the largest trees of this species are at Blenheim. Sang and Nicol say it seldom thrives in Scotland.

The black American or birch-leaved (V. betulifolia), the Canadian (V. manshurica), and the Siberian (V. pallescens) are rapid-growing lofty trees, which, in favorable soils and sheltered situations, speedily produce great bulk of head and timber; but the hoary and the black Italian poplar appear the best for the general purposes of the profitable planter. They are all short-lived trees; flowers from April, and ripen their seeds from a fortnight to a month afterwards.

The wood being soft is used by the sculptor, tanner, and toymaker, and also occasionally by the cabinet and musical-instrument maker, as a substitute for that of the lime. But no limited application of poplar-timber, like the above, can be depended on by the profitable planter, and, therefore, the safest way is to consider it as useful for the common purposes of domestic and rural economy, and more likely to afford profit from bulk than quality. The bark of the black is so astringent, Sang states, as to be used as a laxative. Alluding to the black Italian sort, Pontey says, "In that sort of planting which perhaps may be considered as that of all poplars, the value of a place, previously scantily furnished with that important appendage, wood, this tree is excellent; as, in judicious hands, it may be made to produce very considerable effects, while many others (highly esteemed) would produce them in prospect only. In short, for distant scenery, where wood, not size, is to be considered, this timber, hitherto in many places a stranger, is clearly superior to all the family of the forest." Of the timber of the hoary poplar, he says, Lord Sheffield "has lately made some floors, which, in appearance, are superior to any floor I have seen, whether of deal or oak; and, as to durability, I see no reason to doubt that the density and weight of the article be considered, in conformity to such testimonies as books afford relative to the point. Floors, however, are only one of the many inferior purposes for which it is applicable; as it is certainly proper for almost every article of furniture usually made of mahogany. For the lighter descriptions of it, now so fashionable, it may be made a very good substitute, without any other addition to the natural color of its heart, than the cabinet-makers generally resort to, in order to heighten the color of such wood; and with respect to the sap, and where more of color is required, the aquafortis stain will instantaneously produce it, so far as that it would be difficult to distinguish it from real mahogany. Indeed, it is equal to the best in color and transparency of surface, and much superior to the plain or inferior sorts in those respects, as well as in

Natural soil and situation. None of the sorts mentioned are ever found wild in very poor soils, but generally in such as are deep and moist, but not springy; while rivers and in болотах, the soil being from the surrounding heights, or alluvial deposits have taken place, for ages, poplars are in the greatest perfection.

The willow.—Salix, L. Dioec. Monan. L. and Amentaceae, J. Saule, Fr.; Weidenbaum, Ger.; Salici, Ital. There are two species which seem more immediately to merit cultivation as timber-trees, and several as fit for cultivating in osier-grounds.
7144. The Huntington or common white Lincolnshire swallow-tailed willow (S. alba) (Eng. Bot. 2430.) (fig. 678) grows to a lofty tree, with a branchy stem, and tapering flame-shaped head. It seems common to Europe, being found pollarded by way-sides in Sweden, the south of Russia, and Italy. As a timber-tree it produces a great bulk in a short time; and as a pollard or coppice-wood, on suitable soils, it is prolific in fuel, poles, and bark for the tanner.

7145. The Upland, or red-twigged willow of Pontey (Prof. Plant. 72.) appears to be a variety of the S. alba, being distinguished from it by its hoary or silver-like leaves, and deep red shoots. The timber and mode of growth appear to be the same as those of the Huntington willow, but being of slower growth, the former is to be preferred. Of the red-twigged willow of Sang, there are large trees near Dunfermline, upwards of 60 feet high.

7146. The Bedford willow (S. Russelliana) (Eng. Bot. 1808.) (fig. 679) is also a lofty bulky-headed tree, in general appearance and habits very much resembling the S. alba.

7147. Use. The timber may be used generally in rural economy, and the poles form a light and convenient hurdle. Pontey says, the timber is "considerably durable; a property which, it appears, may be much augmented by steeping some months in water, as is frequently done with os- caplings." The bark of all the sorts mentioned is found to be sufficiently astringent to be now generally used by tanners.

7148. The best willows for osier-grounds are the following:

7149. The common osier, Salix Viminalis. (Eng. Bot. 1898.) (fig. 680) The leaves are long, waved at the edges, but not serrated; shining green above, and silvery underneath. The shoots grow long, straight, and tough, and are well adapted for the larger sorts of baskets, hampers, cranes, and hoops.

7150. The auricled osier, S. stipularis. (Eng. Bot. 1214.) "The two-year-old shoots make excellent rods for baskets, crates, bird-cages, and such articles; and the one-year shoots are used as fillings. The shoots are long, nearly equal in thickness throughout their extent, and somewhat downy, or hoary, particularly at the tops or extremities. The leaves are alternate, with foot-stalks, long and narrow, somewhat notched on the edges, green and smooth above, woolly below. The stipule or leaf-scales are conspicuous and remarkable, resembling a pair of ears."

7151. The green osier (S. rubra) (Eng. Bot. 1145.) is an excellent basket willow. "The shoots are very long, tough, smooth, and of a grey color, occasionally inclining to purplish. The leaves are narrow and very long, from three to four inches, bright green on both sides, and serrated."

7152. The basket-osier, S. Forbyana. (Eng. Bot. 1344.) "The best willow for the finer sorts of basket-work. The shoots are of a yellowish ash-color, sometimes purplish; smooth, very flexible and tough. The leaves are alternate, on foot-stalks, from two to three inches long, somewhat serrated, chiefly towards the top; dark-green above, and glaucous or pale-blush beneath."

7153. The long-leaved triandrous willow (S. triandra) (Eng. Bot. 1454.) is common in osier-beds, and its stools afford most excellent shoots for basket-work, long, slender, pliable and tough; they are smooth, of a brownish color, and towards the top they are fluted or grooved. The leaves are long, and closely and strongly serrated.

7154. The velvet osier, S. mollissima. (Eng. Bot. 1509.) "Its leaves are very smooth and green above, and very silky and soft beneath. Shoots long and very numerous, but not tough; when allowed, however, to remain for two years, they make most capital rods."

7155. The yellow willow, or golden osier (S. vitellina), (Eng. Bot. 1392.) produces "handsome shoots, of a yellow color and shining, and well adapted for basket-work."

---

BOOK IV.

LANDSCAPE-GARDENING.

7156. In landscape-gardening, the art of the gardener is directed to different objects, and some of them of a higher kind than any belonging to gardening as an art of culture. In the three branches hitherto considered, art is chiefly employed in the cultivation of plants, with a view of obtaining their products; but in the branch now under consideration, art is exercised in disposing of ground, buildings, and water, as well as the vegetating materials which enter into the composition of verdant landscape. This is, in a strict sense, what is called landscape-gardening, or the art of creating or improving landscapes; but as landscapes are seldom required to be created for their own sakes, landscape-gardening, as actually practised, may be defined, "the art of arranging the different parts which compose the external scenery of a country-residence, so as to produce the different beauties and conveniences of which that scene of domestic life is susceptible."

7157. What these beauties and conveniences are, must, in different ages and countries, depend on the state of society and climate; and, in the same age and country, on the
wealth and taste of individuals. This art would be a very simple one in rude ages and mild climates, when man had few wants, and scarcely any desires; but, like other arts, would become more intricate as mankind betook to more variable climates, and became more refined in habits and manners. Taking a view, as far as history permits (see Part I.), of the past and present state of landscape-gardening in all countries, the objects desired in the country-residence of a wealthy man, wishing to display his riches, are fundamentally the same. These were and are, adaptation to the habits of genteel life for the time being, as to matters of use and convenience; and distinction from the common scenery of the country, as to matters of taste or beauty in landscape. The first object would principally affect the mansion and accompanying erections for men or cattle; and these would, at first, be merely of greater dimension than those of the common mass of rusticity; but, as society improved, they would be distinguished by more perfect execution, and appendages indicative of the habits of genteel life. The second object, distinction in the surrounding scenery, was and is effected by such dispositions of the common materials of landscape, as ground, water, trees, &c. as indicate the employment of art and expense. In early times, this would produce regularly level or sloping surfaces of ground, and water and trees bounded by straight or geometrical lines, which would distinguish the country-residence from the natural or open unclosed scenery around. In late or modern times, when the general face of the country was disposed in artificial forms, a contrary practice would be pursued, and natural-like scenery would be created for precisely the same object as in the other case; the display of wealth and taste, and the attainment of distinction.

7159. Hence the origin of what are called the geometric and natural styles in landscape-gardening, both evidently founded on the same principle, the love of applause and distinction. The first has been generally condemned as unnatural and absurd; and so it is, if we look upon it as an imitation of nature; but as it never pretended to this, but, on the contrary, was avowedly a display of the power of art over nature, it ought to be judged, like every other work of man, by the end in view; and if, as we have already observed (526.), it be considered as designed to distinguish the garden-scenery of the man of wealth from the common fortuitous scenery of the country in rude or less cultivated times and places, it will be found admirably calculated for that purpose, and just as natural to man as any other part of his habits or manners. But we will even go farther, and maintain that the geometrical disposition of landscape-scenery has powerful beauties, both of the inherent kind, as that of a long broad avenue, or of general or particular associations, as its suitableness to Gothic architecture, very ancient residences, &c. Disapproving, therefore, of that absolute preference of the modern or natural style, which totally excludes the other, we have, in treating of planting (Book III. Chap. IV.), not lost sight of the geometrical dispositions of trees; and we shall, in considering the present branch of our subject, notice also the dispositions of ground, water, roads, &c. peculiar to the geometric style. A knowledge of both will be desired by the liberal-minded practical designer; and the occasional adoption, in part, at least, of the ancient style, will be dictated by general good taste, as well as by the particular tastes of individuals, and the circumstances of peculiar situations. We shall consider, in succession, the principles of composing landscape; the treatment of the materials of verdant scenery; the union of these materials in forming landscapes; and the union of landscapes in connection with scenes of use and convenience in forming country-residences.

Chap. I.

Of the Principles of Landscape-Gardening.

7159. The principles of landscape-gardening, like those of every other art, are founded on the end in view. "Gardens and buildings," Lord Kames observes, "may be destined for use solely, for beauty solely, or for both. Such variety of destination bestows upon these arts a great command of beauties, complex not less than various. Hence the difficulty of forming an accurate taste in gardening, and architecture; and hence, that difference or wavering of taste in these arts greater than in any art that has but a single destination." (Elements of Criticism, 4th edit. vol. ii. 431.) Nor to consider landscape-gardening with a view to these different beauties, but to treat it merely as "an art of creating landscapes," would thus embrace only a small part of the art of laying out grounds, and leave incomplete a subject which contributes to the immediate comfort and happiness of a great body of the enlightened and opulent in this and in every country; — an art, as the poet Mason observes,

"Which teaches wealth and pride,"

"How to obtain their wish — the world's applause."

382
7160. The ancient authors on architecture and gardening have rarely attempted to lay down any general principle of composition. Vitruvius hints obscurely, that the different parts of buildings, should bear some proportion among themselves, like that which subsists between the different members of the human body; that the quantities constituting the magnitudes of temples, should have certain ratios to one another, and he lays down canons for the individual proportions, and collective arrangement of the columns of the different orders. These, however, are not principles, but mechanical rules, formed on very limited associations. The same remarks will apply to the directions respecting the walks, walls, hedges, and borders of the ancient style, laid down by D’Argenville, Claricet, Le Blond, and Switzer. It is in the writings of modern authors, therefore, and chiefly from the enlightened investigations of the Rev. A. Alison, that we are to draw our information as to the principles by which the artists of the ancient style were instinctively guided in their productions.

7161. With respect to the modern style, considered as including what belongs to the conveniences of a country-residence, as well as the art of creating landscapes, Pope has included the principles under, 1st, The study and display of natural beauties; 2d, The concealment of defects; and 3d, Never to lose sight of common sense. Wheatley concurs in these principles, stating the business of a gardener to be "to select and to apply whatever is great, elegant, or characteristic" in the scenery of nature or art; "to discover and to show all the advantages of the place upon which he is employed; to supply its defects, to correct its faults, and to improve its beauties." Repton, whose observations on landscape-gardening bear on the title-page, to be "written with a view to establish fixed principles in these arts," enumerates congruity, utility, order, symmetry, scale, proportion, and appropriation, as principles, "if," as he observes, in one place, "there are any principles." Mason places the secret of the art in the "nice distinction between contrast and incongruity;" Mason, the poet, invokes "simplicity," probably intending that this beauty should distinguish the English from the Chinese style; simplicity is also the ruling principle of Lord Kames; Girardin includes every beauty under "truth and nature," and every rule "under the unity of the whole, and the connection of the parts;" and Shenstone states, "landscape or picturesque gardening" to "consist in pleasing the imagination," by scenes of grandeur, beauty, and variety. Convenience merely has no share there, any farther than it as pleases the imagination. Congruity and the principles of painting are those of Price and Knight; and nature, utility, and taste, those of Marshall. From these different theories, as well as from the general objects or end of gardening, there appear to be two principles which enter into its composition; those which regard it as a mixed art, or an art of design, and which are called the principles of relative beauty; and those which regard it as an imitative art, and are called the principles of natural or universal beauty. The ancient or geometric gardening is guided wholly by the former principles; landscape-gardening, as an imitative art, wholly by the latter; but as the art of forming a country-residence, its arrangements are influenced by both principles. In conformity with these ideas, and with our plan of treating of both styles, we shall first consider its principles as an inventive or mixed, and secondly as an imitative art.

Sect. I. Of the Beauties of Landscape-Gardening, as an inventive and mixed Art, and of the Principles of their Production.

7162. Works of art, Alison observes, may be considered, either in relation to their design or intention — to the nature of their construction for the intended purpose — or to the nature of the end they are destined to serve; and their beauty accordingly will depend, either upon the excellence or wisdom of the design, the fitness or propriety of the construction, or the utility of the end. The considerations of design, of fitness, and of utility, therefore, may be considered as the three great sources of the beauties of works of inventive art. They have been called relative beauties, in opposition to those of nature and imitative art, which are hence denominated natural or independent beauties. There is a third source of beauty common both to arts of invention and imitation, which is that of accidental beauty, or such as is produced by local, arbitrary, or temporary associations. The beauties of objects, whether natural, relative, or accidental, are conveyed to the senses by the different qualities of matter, forms, sounds, colors, scents, and motion; but form is the grand characteristic of matter, and constitutes in a great degree its essence to our senses. In our remarks, therefore, on the beauties of inventive art, we shall chiefly consider design, fitness, and utility, in regard to form.

7163. The expression of design is displayed by such forms and dispositions, as shall at once point out that they are works of art. Thus regularity and uniformity are recognised in the rudest works of man, and point out his employment of art and expense in their construction. Hence the lines, surfaces, and forms of geometric gardening should be different, and in some degree opposed to those of general nature. Irregular surfaces, lines, or forms, may be equally useful, alike works of art, and, considered with reference to other beauties, may be more agreeable than such as are regular; but, if too prevalent,
they might be mistaken for the production of nature, in which case they would lose the beauty of design; but forms perfectly regular, and divisions completely uniform, immediately excite the belief of design, and with this belief, all the admiration which follows the employment of skill and expense. Ground in level or regular slopes, or in hills or hollows of symmetrical shapes; woods of right-lined boundaries; trees, and especially such as are foreign to the soil, planted equidistantly in masses, in quincunx, or in straight rows; water in architectural basins, regular canals, or fountains; walks and woods, of uniform width and perfectly straight; straight walls and hedges are easily distinguished from nature's management of these materials, and are highly expressive of the hand of man.

7164. Regular forms are satisfactory, Stewart observes (Philosophical Essays, 238.), "from the principle of a sufficient reason, adopted by Leibnitz. What is it, that in any thing which is merely ornamental, and which at the same time does not profess to be an imitation of nature, renders irregular forms displeasing? Is it not, at least, in part, that irregularities are infinite; and that no circumstance can be imagined which should have decided the choice of the artist in favor of that particular figure which he has selected? The variety of regular figures, it must be acknowledged, is infinite also; but supposing the choice to be once fixed about the number of sides, no apparent caprice of the artist in adjusting their relative proportions, presents a disagreeable and inexplicable puzzle to the spectator."

7165. Wherever symmetry "is useful to the soul, and may assist her functions, it is agreeable to her; but wherever it is useless, it becomes distasteful, because it takes away variety: therefore, things that we see in succession ought to have variety, for our soul has no difficulty in seeing them: those, on the contrary, that we see at one glance, ought to have symmetry; thus at one glance we see the front of a building, a parterre, a temple; in such things there is always a symmetry which pleases the soul, by the facility it gives her of taking the whole object at once." (Montesquieu.)

7166. The expression of design, in the progress of the arts, though at first difficult, becomes afterwards easy, and renders regularity and uniformity only expressive of common design. Hence, to confer a character of superiority in works of design, variety would be introduced; and as uniformity was the sign of design, so uniformity and variety would become the sign of improved or embellished design. "Considering, therefore, forms in this light as beautiful, merely from their expression of design, the observation of Dr. Hutcheson may perhaps be considered as an axiom with regard to their beauty, viz. that where the uniformity is equal, the beauty of forms is in proportion to their variety; and when their variety is equal, their beauty is in proportion to their uniformity." (Alison's Essays, p.106.) To this stage, in the progress of design, may be referred the architectural ornaments introduced in garden-scenery, such as seats, buildings, statues, urns; and in the later stages of the art, serpentine walks, labyrinths, verdant sculpture, and many other improvements. The variety and embellishment thus conferred on gardens produced in time many absurdities, that we would not wish to see resorted to with a revival of the ancient style, unless in examples considered solely with a view to imitation. The sculpture of trees, however, might, when first introduced, be greatly admired, even by men of sense, for its novelty, and the discovery of a certain degree of skill in the artist; but as, in our times, they would neither be new nor meritorious, they could scarcely be consistently introduced with a view to embellish design.

7167. To prevent variety from degenerating into confusion, and as Professor Stewart characteristically expresses it, "puzzling the spectator," unity of intention must never be lost sight of. This, indeed, is necessarily implied in every work of art, since, without it, the slightest attempt at design would only end in a chaos of materials.

7168. Fitness, or the proper adaptation of means to an end, is the second source of the relative beauty of forms. Considered in relation to the parts of a building, it is generally denominated proportion, and refers to the adequate strength of certain parts to bear certain weights, &c. In the detail of the ancient, and in scenes of relative beauty in the modern style of gardening, it relates to the magnitude and situations of buildings, and other artificial objects, relative to natural ones,—to the extent of the different scenes or constituent parts of a residence, compared to the whole,—to the propriety and congruity of certain objects as ornaments,—and, in general, to the adequacy of means to an end, whatever these means or that end may be.

7169. Utility is the third source of the relative beauty of forms. None of the other beauties will compensate for the entire want of utility in any scene of architecture or gardening. Objects at first thought beautiful, soon lose this expression when they are found to be of no use; and others, with first impressions the most disagreeable, are felt to become beautiful as they are known to be useful. "This species of beauty," Alison observes, "is in itself productive of a much weaker emotion than that which arises from the different sources of ornamental beauty; but it is of a more constant and permanent kind, and much more uniformly fitted to excite the admiration of mankind." (Essays on
PRACTICE and, but but "santest correct Llandscape-Gardening, spot, professional beautiful, command by and bors, appropriation, of simplest their creates notched but those expressions are at variance; when the beauty of the form cannot be produced without sacrificing its utility; that form will be most universally and most permanently beautiful, in which the expression of utility is most fully preserved." (Essays, vol. ii, p. 202.) Some of the various modifications of utility, as applied to country-residences, may be here enumerated.

"To unite these different kinds of beauty; to dignify ornamental forms by use; and to raise merely useful forms into beauty, is the great object of ambition among every class of artists. Wherever both these objects can be obtained, the greatest possible beauty that form can receive will be produced. But as this can very seldom be the case, the following rules seem immediately to present themselves for the direction of the artist: — 1. That where the utility of forms is equal, that will be the most beautiful to which the most pleasing expression of form is given. 2. That where those expressions are at variance; when the beauty of the form cannot be produced without sacrificing its utility; that form will be most universally and most permanently beautiful, in which the expression of utility is most fully preserved." (Essays, vol. ii, p. 202.) Some of the various modifications of utility, as applied to country-residences, may be here enumerated.

1710. For the purpose of habitation, for example, good air and water, a genial climate, fertile soil, cheerful prospect, and suitable neighborhood, &c. are known requisites. Convenience must be joined to use, comfort to luxury, and beauty to propriety. The most distant glimpse of the object which is put into motion, riding, or driving, requires to be provided for; and recreation, whether in the common field sports, athletic games, or in botanical, agricultural, and other useful, elegant, or scientific pursuits, must be kept in view: rural fêtes and amusements might also be enumerated.

1711. Accidentes associations form the last class of relative beauties, and are "such associations as, instead of being common to all mankind, are peculiar to the individual. They take their rise from education, from peculiar habits of thought, from situation, from profession; and the beauty they produce is felt only by those whom similar causes have led to the formation of similar associations. (Stewart's Essays.) Among these may be reckoned those which are connected with the business of the landscape-gardener. It is that interest which the attachment to property creates in men's minds, "rendering them alive to every trifling recommendation belonging to what is their own, while it blinds them to the most prominent beauties in the property of their neighbors." (Stewart's Essays, p. 483.)

1715. Appropriation, or such an arrangement as shall, either in reality or appearance, render all, or the greater part of what we see from a country-seat our own, is a consequence of personal associations. The simplest way of effecting this, is by shutting out all objects which do not correspond with the idea, by means of what is called "the separate view." A separate view is obtained either by surrounding the object with a fence, which secures the beauty of the forms, colors, and arrangements in our own territory (6769.), which appear in those of our neighbors, as seen from the house, or some particular point of view. According to Wheatley, "one property of a riding is to extend the ideas of a seat, and appropriate a whole country to the mansion." For this purpose, he requires the object of the riding to be different from common roads in form and preservation, and distinguished by accompaniments borrowed from a park or garden, &c. Knight strongly objects to appropriation, and ridicules certain attempts of this sort, made by placing the family arms on the inns and public-houses of the neighborhood, and on "a sort of sign, or notice, or recommendation, or prop, by one improver. Girardin also objects to the principle; but Repton, and we believe, almost every other professional man, finds it a very principal object of attention. Repton declines appropriation to be, "that combination of circumstances, which makes visible to the window what is nearest to the place." A view from a London house into a square or into the parks may be cheerful and beautiful, but it wants appropriation; it wants that charm which only belongs to ownership — the exclusive right of enjoyment, with the power of refusing that others should share our pleasure. The most romantic spot in the world is a delightful situation, and the most warlike semblage of nature's choicest materials will not long engage our interest without some appropriation; something we can call our own; and, if not our own property, at least that may be endeavored to us by calling it our own home." ( Fragments of Landscape-Gardening, 3d ed. p. 200.)

"I stick still in the inn of a hired house," writes the amiable Cowley to Evelyn, "without that pleasant work of human industry, the improvement of something which we can call our own."
pole, when he represents it as "proud of no other art than that of softening nature's harshness, and copying her graceful touch." It has also been said, that it is "to poetry and painting, what the reality is to the representation." (Girardin.) But experience proves, that the former (the reality) is always exceeded by the latter, both in respect to natural and picturesque beauty. Suppose, for example, any given variety of ground, rocks, and distance, as the basis to be furnished with wood, water, and buildings; the rocks shown, or concealed, as the gardener may wish, or as the genius of the place may require, and every other purpose effected, which is in the power of gardening to perform.

When all this is done, it will be a scene greatly inferior in beauty to the imitative creation of a painter from the same groundwork and materials; or, let there be a natural landscape, either of mediocrity or of any given beauty, with every circumstance so arranged, as to be alike suitable for both arts; and let a painter and a gardener, each attempt to copy it according to their art, with or without permission, to improve its beauties. Which of the two imitations would be most beautiful, considered in the abstract, and without reference to any selfish or arbitrary association? Decidedly, in our opinion, the production of the painter. In short, no comparison between the powers of landscape-painting and those of landscape-gardening can be instituted, that will not evince the superior powers of the former art. The great source of the beauty of every verdant landscape is wood; and so much of the beauty of all woods depends on accidental circumstances, in their progress from the time of planting, till they attain a considerable age, and which circumstances cannot be said practically to be under the control of the gardener, that however high our aim, however we may study the natural effects of time, and however correctly we may imitate them, at the end of all our labors, any wood of art will always be far inferior to a wood of nature under the same circumstances. For further illustrations, we have only to appeal to such painters as have made landscape their particular study, and who certainly must be considered in this case as the best judges with regard to scenic truth or picturesque beauty.

7177. To what kind or degree, of beauty then, can landscape-gardening aspire? To this we answer, that, abstracted from all relations of utility and design, it can seldom succeed in producing any thing higher than picturesque beauty, or such a harmonious mixture of forms, colors, lights, and shades, as will be grateful to the sight of men in general; and to such, more particularly, as have made this beauty in some degree their study. This harmonious assemblage of objects may be grateful and agreeable, without being accompanied by any, or at all events, by much general expression; for example, of gaiety, melancholy, grandeur, simplicity, or elegance; but it may also combine one or more of these poetic or general beauties in a high degree, and this, too, with or without being picturesque. It may recall many other pleasurable emotions, if we admit the considerations of fitness, novelty, or its contrast to surrounding scenery, and utility or its adaptation to man. Such is our opinion of the capacities of landscape-gardening. If it is lower than that of some authors and artists, we can only say, that it has been formed from the observation and experience of what actually takes place. The artist may and ought to aim at the highest degree of beauty, which his own imagination, the genius of the place, and the views of the owner, will admit of; but let him not proceed with, or hold out to the world, mistaken views of what his art can and cannot perform.

7178. The principles of imitative landscape-gardening, in that view of this term which limits it to "the art of creating landscapes of picturesque beauty;" we consider with Girardin, Price, Knight, and other authors, to be those of painting; and in viewing it as adding to picturesque beauty some other natural expression, as of grandeur, decay, melancholy, &c. we consider it, with Pope, Warton, Gray, and Eustace, as requiring, both in the designer and observer, the aid of poetic mind; that is, of a mind conversant in all these different emotions, or pleasures of imagination, which are called up by certain signs of affecting or interesting qualities, furnished by sounds, motion, buildings, and other objects.

7179. If taking a third view of imitative landscape-gardening, as "the art of laying out the grounds of a country-residence," then, with popular opinion, we comprehend under the term all the above beauties, with those of relative beauty, the principles of which have been the subject of the preceding section. The principles of landscape-gardening then, as an imitative art, we conclude to be derived from nature, as developed by the principles of landscape-painting; and, as recognised by poetic mind, or a mind alive to those general beauties or associations universally felt in civilised society. We consider this, perhaps to many a tedious development of the principles of landscape-gardening, called for by the vague and indefinite manner in which they are spoken of by authors, no less than by artists; and, as a proof of this, we refer our readers to the volumes of the late Mr. Repton, who, whatever may be the merits of his practical taste, has certainly, whenever he has touched on the subject of principles, written in a very unsatisfactory manner.

To those who are conversant with the literature of landscape-gardening, it must appear a very gratuitous task to write a book "with a view of establishing fixed principles" in the
art, and to find in such a book, after the publication of the works of Wheatley, the two Masons, De Lille, Price, and Knight, such a passage as the following: "If any general principles could be established in this art, I think they might be deduced from the joint considerations of relative fitness or utility, and comparative proportion or scale; the former may be referred to the mind, the latter to the eye." (Obs. on L. Gardening by H. Repton, Esq. Introduction, p. 2.) While we disapprove of this disingenuous mode of writing, the frequency of which we must regret in this artist's works, we willingly pay tribute to his practical good taste, and more especially in architecture.

7180. As an illustration of the theory of landscape-gardening, which we have adopted, we subjoin a slight analysis of the principles of a composition, expressive of picturesque and natural beauty. For this purpose, it is a matter of indifference, as far as respects picturesque beauty, whether we choose a real or painted landscape; but, as we mean also to investigate its poetic or general beauty, we shall prefer a reality. We choose then a perfect flat, varied by wood, say elms, with a piece of water, and a high wall, forming the angle of a ruined building; it is animated by cows and sheep; its expression is that of melancholy grandeur; and, independently of this beauty, it is picturesque in expression; that is, if painted it would form a tolerable picture.

7181. Unity is the first obvious principle which pervades this picture. No ideas of gaiety or prettiness are excited by such a scene. All the parts unite in forming a whole, which the eye can comprehend at once, and examine without distraction. "La vue," says Girardin, "le plus vagabond de tous les sens, a besoin de se ravitailler. When this maxim is applied to a garden, every variety of trees, the lake, the building, would only please when considered separately, and the result would be as poor a production as a machine, the wheels of which are accurately finished and nicely polished, but which is so contrived as to be intended merely for the purpose of opening

7182. It is true to nature; that is, the objects or materials are what they appear to be. The trees, which are neither very old nor very young, though in the distance diminished by their remote situation, we discover by their trunks and contour, to be still trees. They are not shrubs placed near the eye, with a view to produce a false perspective; such as in the representation of buildings, where the openings which have once been windows, and is crowned in one part by battlements. The water is natural, its surface being below the level of the adjoining ground, not raised above it, as is often the case in artificial waters. This completes the truth or reality of the scene. The necessity of adhering to truth is still greater in landscape as a whole; for this art, according to what appears to be natural, not only in forms and color, but also relatively to the forms and colors around them. Objects, especially those whose forms and dimensions are familiar to us, as men or horses, painted of different heights in the same plane; as, for example, in the distance, of the same magnitude as that in which they appear in life, would, from the acquired habit of measuring unknown by known objects, give a falsehood to the scene, and appear as animals of a different species, or as monsters. It seems to be from the same principles of being true to nature, that a gradation of scene, or what is called distance, is required, or at least is so satisfactory in landscape. The mind, after being attracted by the effect of contrasts of light and shade in order to succeed, there must be a transition and obvious the arrangement of these parts, therefore, the more readily does the mind accede in their effect. The eye of the artist, seizing on the nearest and most remote parts of a scene, readily marks an intermediate or middle distance; no given extent seems necessary for this purpose:

"To make the landscape grateful to the sight,
Three points of distance always should unite;
And howso'er the view may be confin'd,
Our divisions we should think.

The Landscape, by Knight.

7183. The disposition of the parts is the next object of analysis, and the enquiry is how in this respect they concur in forming a whole. 1. As to forms, we find that their disposition is in groups or masses. The largest group, for example, is placed towards one side of the picture in the foreground, another towards the opposite side of the middle distance, including the building and adjoining lake; and the remote, or rising parts, consists of a large clump of rough wood, and shrubs. 2. As to colors, we find only different shades of yellow and green on the trees and ground. 3. As to the light, we find one large and principal light near the middle of the view, diverging into shade as it approaches the sides; the clearest part is the water, and the next clearest the building, and the third light spreads over a broad space of ground, near the water. The groups in the foreground are all in a deep shadow. One of these, near the water, partakes of the principal light, and those in the third distance are distinguished by a sort of neutralisation of light, color, and shade. Such is the disposition of the groups or parts, in order, in a complex view of the whole, to fix the eye, and prevent it from being distracted by scattered lights, confusion of forms, and inharmonious color.

7184. The connection which subsists between these different parts is a subordinate but important consideration. They are connected in each distance by a real heness of situation; and, 2. In the view as a whole, from the one group to the other, is introduced, in part before the eye, by the same contrariety of objects and apparent proximity. Suppose the reverse to be the case, and that the groups were unconnected either by real or apparent distance of situation, the consequence would be, that each group being surrounded by light, would become a distinct object. The eye would have no resting place, and the assemblage would not compose a whole.

7185. The relation which subsists between the parts, composing each individual group, is next to be examined. 1. In regard to the form of the parts of each group, as they are all groups of the same sort of tree, we find one elementary form prevalent, but differing in magnitude, and in combination, by their contrasted disposition, to such a degree, that each group differs in form from the others, without at the same time being of opposite forms.

7186. In order to follow, the same kind of color prevails in each and in all of the groups, but is varied in degree by the same contrasted disposition. In some parts a yellowish-green prevails, in others a greenish-yellow, in others a russet or red-green, and occasionally a bright-green, as on that part of the turf where the light strikes with the greatest force.

7187. Without further account, the form of the parts, those parts of the groups which rise above the horizon, and are backed by the sky, are dark, and generally darker than such as are backed by the ground, or by other adjoining groups. The prominent parts of each group are lighter than the retiring parts or recesses among the preceding and retirings. The groups in the third distance are lost in the general aerial shade of the group. It may be observed, as a general principle, that trees, from their rough surface, and consequent imperfect reflection of light, are always comparatively darker than water, buildings, or ground. In creating real landscape, they serve in some measure as shades, as the other materials mentioned serve as lights.

7188. The sky, the cows, and the sheep, must be noticed in order to complete the sketch. Suppose, then, that the sky is merely grey and cloudy, and the cattle and sheep grouped in the middle distance,
what will be the expression of the view? We think it would express very little to general observers; but there being nothing glaringly offensive in the arrangement, it would be expressive of some beauty to him who had bestowed some attention to the subject of landscapes; for though it exhibits but little harmony of forms and colors, light or shade, it still possesses enough of these ingredients to render it worth looking at as a picturesque view.

7189. The general or natural expression of melancholy and grandeur remains to be accounted for. For this purpose, let the building be the ruins of an ancient castle, whose lofty quadrangular form may be readily imagined from the walls we mentioned, as composing a part of the scenery. The character of grandeur, then, is not in this instance communicated to the picture, by the picturesque effect of the walls, which have no variety of form, light, or shade, in themselves, but by the mental associations to which they give rise in a cultivated mind.

7190. As another example of picturesque, and poetic, or sentimental expression, imagine the cattle and sheep removed, the surface of the ground covered by smoothly mown turf, and the luxuriant branches of some of the foreground trees nearly reclining on the ground. The first expression would be that of beautiful, or elegant picturesque; the next that of stillness, and consecration to man,—stillness, as being without animals or moving objects; and consecration to man, from the mown surface, greatly heightened by the circumstance of the branches of trees reclining on the ground, which never can happen where sheep or cattle are admitted, and which forms the leading visible distinction between a group of trees in a park, and a group on a mown lawn. It is not from the smoothness of the turf, or any particular mixture of light and shade in the reclining branches, that this expression is produced, but from reflecting on the cause of this appearance.

7191. As a third example, imagine, instead of the smooth turf, uncouth rough ground, covered in some places with furze, briars, brambles, and tangled thickets; the water fringed with rushes, and partially concealed by aquatic shrubs; and wild horses and deer forming the animated part of the scene. The expression would be eminently picturesque; but there would also be an expression of wildness, not resulting from the picturesque qualities as such, but from mental reflection on the difference between this scene and one of cultivation.

7192. As a fourth example, imagine the view deprived of the lake and the building, and consisting only of the wood and ground, with the heads of a straggling row of willow-trees appearing in the middle distance, and the sound of a distant waterfall heard through the trees. Here, to picturesque beauty we have an idea of water—of an immense body of it in the lake or river which supplies the waterfall—and of the rocks, which oppose their powerful obstruction to a body of water. The reader will here remark, how much of the sublime beauty of this scene depends on sound, which can never be included under picturesque beauty. The leading expression is that of sublimity, accompanied by various associations of dignity produced by the rocks, and of grandeur suggested by the stream, after the waters have renewed their tranquil course, and rolling, as we may imagine, majestically along under the shade of the line of willow-trees.

7193. Other examples, of a more striking nature, might be adduced; but these instances we consider as better adapted to show the difference between a composition merely picturesque, and one expressive of general or natural beauty, and to prove our position, that both poetry and painting enter into the principles of imitative landscape-gardening. They will also show, how very little the production of natural beauty is within the power of the landscape-gardener. He may display it to more advantage. In the first example of expression, for instance, the building, or such parts of it as more obviously show its real character, might be displayed by the removal of some over-obtruding branches; and in the second, a garden-seat, and some garden-trees, as the lime, cedar, &c. might add to the idea of consecration to man. In the third, a corn-field or a barn in the distance, would aid the effect by contrast; and in the last, a bridge would determine the situation and reality of the river. But to attempt effecting these expressions by building a ruin, placing a garden-seat in a paddock, or erecting a bridge where there was no water, would, however common in the infancy of the art, be now justly considered ridiculous. Much more, it is true, might be done in improving the picturesque beauty of each of these scenes, provided the trees were already grown to maturity, and too numerous rather than too few; but if the trees are yet to plant, it is evident that only the ground-plans of the masses and groups of trees, and of the breadth of the lawn, could be formed by the artist.

7194. A very common error, since the introduction of the modern style, has been to suppose that picturesque beauty is the only beauty to be aimed at in laying out grounds; but so far from this being the case, it will often happen that the alterations required for
the purposes of convenience and character, will lessen that beauty, whilst it increases that of dignity, refinement, and appropriation to man. As an example, we may refer to Rivenhall Place, in its state before being improved by Repton (fig. 681.), and the same residence subsequently to improvement, or as intended to be improved. (fig. 682.) Every one will allow that its unimproved state (fig. 681.) presents the most picturesque landscape; while its dressed state is the more dignified and desirable as the landscape of a considerable country-residence.

Chap. II.

Of the Materials of Landscape-Gardening.

7195. The materials of landscape-gardening with which we work in order to obtain the desired effect, are the same whatever style we adopt. Those of nature, are ground, wood, water, and rocks; to these, art has added buildings, roads, walks, fences; and animated or moving objects, sounds, &c. may be considered as accompaniments only partially under our control.

Sect. I. Of operating on Ground.

7196. The operations of art on this ponderous material are necessarily of a very limited description. The most extensive and costly operations, to restore or create natural surfaces, even when attended with the desired effect, afford less permanent gratification to personal feeling than most other improvements. If a deformed space has been restored to natural beauty, we are delighted with the effect, whilst we recollect the difference between the present and the former surface; but when this is forgotten, though the beauty remains, the credit for having produced it is lost. In this respect, the operations on ground under the ancient style, have a great and striking advantage; for an absolute perfection is to be attained in the formation of geometrical forms, and the beauty created is so entirely artificial (fig. 683.) as never to admit a doubt of its origin. Long, therefore, after the improvement is finished, the credit and the beauty remain to gratify and charm the owner. Improvements on surfaces, whatever be their object, ought to be made in scenes which are near the eye, or intended to be frequently seen; at a distance they are lost if the effect be on a small scale, and often better effected by wood, if on one of considerable magnitude. Attempts to remove distant inequalities, by lowering heights and
filling up hollows, very seldom are attended by results sufficient to justify the expense incurred; but when art is employed to heighten distant eminences the success is greater; in the last case art may be said to act positively, in the former negatively—to produce or increase a beauty, instead of only removing or lessening a deformity. All operations on ground may be included under, 1. Those which have for their object the beauty of art or design; and, 2. Those where natural beauty is intended to be produced.

7197. Operations with a view to relative or artificial beauty. The forms in use for this purpose are few and simple. They originate in, and are influenced by, those of the house; and, for the greater part, bounded by right lines; and the surfaces are levels or slopes of different degrees of abruptness. The magnitude as well as form of each of the figures in the ground immediately adjoining a house, or in a detached walled enclosure, should be regulated chiefly by the magnitude of the mansion, or extent and grandeur of the whole place, though they are often obliged to conform, in some degree, to the natural surface. When the ground slopes from the house in all directions, narrow parallelograms will be the prevailing forms both of the levels and slopes. The broadest level, and greatest perpendicular depth of slope, will generally be placed next the house, and the next broadest level, &c. in succession, till, after three or four levels, and as many slopes are obtained, the artificial surface shall finally blend with the natural; unless, as is frequently the case in the geometric style, a kitchen-garden wall, or some similar work of art, forms the termination. In this case, separation by some architectural or other accompaniment, will, by forming a break in the order of forms, admit of adopting, in continuation of the artificial surface, such levels and slopes as the character of the scene may require, or a due regard to economy dictate. When the mansion, or scene of operations, is on a surface naturally flat, the levels will be of greater dimensions, the slopes smaller, and both fewer in number. But though parallelograms are the common figures employed, sections of polygons, trapeziums, circles, and curvilinear figures, are frequently admitted. They are used in architectural elevations, and in fortifications, which are the prototypes of this part of ancient gardening; and, therefore, when apparent in the mansion, should be reflected, as it were, by the grounds. (fig. 684.) The forms to be used, however, is a matter easy to determine. The principal difficulty is to arrange them together, so that they may concur in producing a whole, or a good effect. In disposing, connecting, relating, and contrasting them for this purpose, the artist will preserve regularity and uniformity in the complex view of the whole, varying and harmonising the detail according to the degree of beauty and variety he intends to produce. If he has duly prepared his mind by theoretical studies, and practised architectural and landscape drawing, his own feeling of their impression will suggest when he has attained the desired effect; for the models of artificial surfaces which remain of ancient gardens are poor productions compared to what might be created in this way, through the judicious application of the principles of relative beauty. A good deal depends on adjusting the extent of geometrical or architectural surface to the size of the house and surrounding grounds; and in this matter much depends on the regularity or irregularity of the ground plan of the former, and on the evenness or variation of the surface of the latter. A square house on a level, or on a gentle swell, will require least extent of architectural platform around it, and a straggling gothic castle on an irregular declivity the greatest extent of terraces, angles, ramps, and slopes.

7198. Natural beauty of ground. As the right lines and geometrical forms of the architect, take the lead in grounds of artificial beauty, so the flowing and broken lines, and undefined forms of the landscape-painter, take the lead in those of natural beauty. To create them in ground, is generally impracticable and unadvisable; but where they exist concealed by accidental deformities, or incomplete in expression, through dulness in their leading features, art may relieve from the impediments to beauty, even though the situation is at some distance from the eye. In recluse scenes immediately under view, art may aspire to create beauty even from a tame flat, but especially from its opposite, a flat abounding with deformities. In effecting all those purposes, the same principles apply. The first thing to fix in the mind is the desired surface, or that style of natural ground which is best to be imitated. The next thing is to examine on what parts, forms, and lines, the natural beauty of this ground chiefly depends; if undulating, whether the concave or the convex prevails; if broken ground, whether horizontal and perpendicular, or curved and inclined lines prevail. These are then to be imitated in the improvement, ever keeping in view the important principle of a whole as the end of the connection, and harmony of the parts of which it is composed.
7199. The removal of accidental deformities forms one of the commonest operations on ground. Old quarries and other pits, useless cattle-ponds, open drains, mounds of earth, marks of ridges, are to be considered of this description. As they have been raised by art, so in dispersing them, the best general rule is to restore the natural surface; but sometimes the remains of fences are so numerous, that advantage may be taken of the earth to be removed, and some variety given to a surface otherwise dull and featureless. If the fence consists of a great number of turns of different lengths, by removing both the mound and part of the surface on each side of the drain, a small winding hollow or vale may be formed: the effect of which may be heightened, by placing the earth removed on adjoining indications of natural eminences; not so as to form knolls, but so as to connect and harmonise with the prevailing idea of expression. The most simple and obvious improvement of exhausted quarries and dry pits, is to plant them (fig. 685); this, though it will form a series of pleasing scenes, is not always consistent with the general expression to be created, and such groups as would arise from these spots, might destroy breadth of light and connection, independently of excluding distant objects. In this case, they must be filled up by under-growths, or by lowering the adjoining surface in such a way as not to interfere with general effect, or a sufficient descent for the surface-water. Where broken ground enters into the idea of the composition to be effected, open drains, or hollow pits, afford fine sources of picturesque beauty, especially if the ground is dry, or can be readily under-drained. This character, however, can seldom be introduced as an original feature; but in ground naturally leading to abrupt and broken lines, it may be more desirable to improve this expression, than attempt creating a more polished surface. In cases of this sort, almost every thing depends on the introduction of wood, copse, and verdant roughnesses, to harmonise the broken surface; for mere broken ground, without a character of luxuriance and wildness communicated by wood, is seldom better on a smaller scale than a surface deformed by scars.

7200. Natural bumps or exences (fig. 686. a), as well as pits (b), are not uncommon in many grounds which have not been subjected to agricultural improvement.

When these are not large, the process of fallowing with the plough will remove them; when they are of some magnitude, they may often become sources both of polished and picturesque beauty. If they are numerous and favorably distributed, by the removal of some, and the enlargement through that means of others, they may give an impression of undulation, especially if situated on a naturally irregular surface. If on a declivity, and covering rocks or huge stones, a mixture of flowing lines with abruptnesses may be happily introduced.

7201. A varied but yet dull surface may often be improved by a skilful artist. By studying the character indicated by nature, it will generally be found, that the deficiency of expression is owing to the hollows being in part clogged up, either naturally or by long continuation under the plough; and the swells lowered in a corresponding degree by the same process. In this case, the obvious improvement is to remove earth from the hollows, and place it on the eminences, ever keeping in view the natural expression, and avoiding to end the improvement, by leaving the hollows gutters, and the eminences pointed ridges. This sort of improvement is not a very obvious one, though often attended with surprising effects, for every foot of depth taken from a hollow, and laid on an adjoining hill, adds two feet to the height of the latter. All these observations will be understood as referring to grounds near the house.

7202. Distant scenes of a park, as hills, or mountains (fig. 687.), are only to be improved by wood; and these remarks, in so far as they extend, will suggest not what is to be removed, but what must be concealed. Many excellent hints on this part of the subject are to be found in the picturesque tours of Gilpin, referring to ranges of
hilly scenery in different parts of the country, of much of which he has given views. With respect to ground, as respects garden-scenery, almost the only writer who has treated of it at length is Wheatley, whose excellent book, so frequently referred to by all succeeding writers on gardening, ought to be in the hands of every man of taste. In the chapter on ground in that work, the author concludes with a salutary caution, which ought ever be taken in connection with the wisest rules; "a caution which has more than once been alluded to, must always be had in remembrance; never to suffer general considerations to interfere in extraordinary great effects, which rise superior to all regulations, and perhaps owe part of their force to their deviation from them. Singularity causes at least surprise, and surprise is allied to astonishment. These effects are not, however, attached merely to objects of enormous size; they frequently are produced by a greatness of style and character, within such an extent as ordinary labor may modify, and the compass of a garden include. The caution, therefore, may not be useless within these narrow bounds; but nature proceeds still farther, beyond the utmost verge to which art can follow, and, in scenes licentiously wild, not content with contrast, forces even contradictions to unite. The grotesque, discordant shapes which are often there confusedly tumbled together, might sufficiently justify the remark. But the caprice does not stop here; to mix with such shapes a form perfectly regular, is still more extravagant; and yet the effect is sometimes so wonderful, that we cannot wish the extravagance corrected." (Obs. on Mod. Gard. p. 28.)

Sect. II. Of operating with Wood.

7505. Wood produces almost all the grand effects in both styles of improvement; for trees, whether in scattered forests, thickets, or groups, or in compact geometric squares, avenues, or rows, constitute the greatest charm of every country. Trees improve the most varied outlines of buildings (fig. 688.), and without them the grounds of a residence (fig. 689.) would often be nothing more than an unmeaning profusion of winding roads or walks. A tree in itself is, indeed, the noblest object of inanimate nature; combines every species of beauty, from its sublime effect as a whole, to the individual beauty of its leaves; exhibits that majestic uniformity and infinite variety which constitute the essence of relative beauty; and the natural expressions of individual species are as various as are their forms and magnitude, their utility to man, and the situations, soils, climates, and other general and accidental circumstances of which they are indications.

7204. The effect or expression of trees, individually and in masses, has been entered on at length in the preceding book; we shall here, therefore, confine ourselves to a few general observations on the effect of planting in the geometric and modern manners.

7205. In planting in the geometric style, the first consideration is the nature of the whole or general design; and here, as in the ground, geometric forms will still prevail, and while the masses reflect forms from the house, or represent squares,
triangles, or trapeziums, the more minute parts, characterised by lines rather than forms, such as avenues, rows, clumps, and stars, &c. are contained in parallelograms, squares, or circles. In regard to the parts, masses and avenues should extend from the house in all directions, so far as to diffuse around the character of design; and as much farther in particular directions as the nature of the surface admits of, the distant beauties suggest, and the character of the mansion requires.

In disposing these masses, whether on a flat or irregular surface, regard will be had to leave uncovered such a quantity of lawn or turf as shall, at all events, admit a free circulation of air, give breadth of light, and display the form of the large masses of wood. Uniformity and variety as a whole, and use as well as beauty in the parts, must be kept constantly in view. Avenues, alleys, and vistas, should serve as much as possible as roads, walks, lines of fences, or screens of shelter or shade; but where this is not the case, they should point to some distant beauties, or near artificial objects, to be seen at or be beyond their termination. The outer extremities of artificial plantations may either join natural woods, other artificial scenes, cultivated lands, or barren heaths or commons.

7206. When artificial plantations join natural woods, the avenues, alleys, and circular glades of the former may be continued a certain length in the latter, so that the point where the natural wood begins, and the artificial plantation ends, may not be discoverable. In aid of this effect, the sort of tree which prevails in the natural scenes, should also prevail in the adjoining parts of the artificial wood. When artificial scenes join other artificial scenes, nothing can be easier than by the reciprocal continuation of avenues, strips, or masses, so far to unite the two seats, as to conceal the boundaries of each, while the two mansions will thus each borrow a splendor from the other. There are still existing proofs of the attention paid to this subject in former times, an instance of which occurs in the apparent connection by avenues between Blenheim, Ditchley, and Heythrop, though the last mansion is nearly ten miles distant from the first.

7207. When artificial scenes join cultivated lands, if those lands are enclosed, broad strips, hedge-rows, square or round clumps in the angles of the fields, with such reciprocal disposition of lines or forms as the case may suggest, will continue the character of artificial plantation; and where roads are necessary, if utility does not forbid, they should be formed in part as avenues, in continuation of those within the artificial scene.

7208. When artificial plantations are bounded by barren heaths or commons, all that can be done is to advance beyond the boundary of the place portions of avenues, and rows of trees of different lengths. Sometimes an inequality, crowned by a clump or thicker,
may promote the idea. On other occasions, where the heath or waste may be so bleak as to convey no agreeable expression, and therefore is, of course, struck out entirely from the improved scene, a sort of connection may be given, by advancing strips or rows from the boundary plantation into the heath. Even single or scattered trees, if they can be protected in that situation, will have a tendency to produce that sort of connection required; and, while it gratifies the proprietor's love of appropriation, will please the eye of the traveller, who views the country as a whole, and delights to observe the harmony and beauty of its principal features. Having disposed of the whole, and of the parts, as far as respects their general effect and connection, what remains to be considered is, the sort of tree, manner of disposing the plants, fences, and future management.

7209. When the object in view is the expression of art and design, the propriety of employing species of trees different from those which are natural to, or most abound in the surrounding country, is obvious. In a country of common pine, the spruce and silver firs and cedar afford a choice. In a country of oaks or elms, chestnuts, limes, and places, form suitable contrasts. Where the plantations are extensive, the value of the timber must always be a principal object; and, therefore, the contrasted trees should be chosen accordingly. Some species, however, are so happily adapted for this style, and as ornamental trees in both styles, that they ought seldom to be omitted excepting near the house: such for example, as the horse-chestnut, lime, Spanish-chestnut, plane, luccombe oak, cedar, stone pine, &c. As the four last species mentioned are, in exposed situations, liable to injury from extraordinary severe winters, a few harder sorts, resembling them in general appearance, should be intermingled in the plantation, to preserve the larger masses in case of accident, but to conform with the general effect in color and style of foliage, as well as in form. Different species ought not in general to be mixed together in the masses; one, or at most two, conforming varieties are sufficient; more would destroy the breadth of color of the mass, and the character of its surface. Different masses, avenues, and more minute parts, may, however, be planted with different species of trees; rare sorts may be also introduced in lines, along the front of many of the masses, ranged along stars, crosses, &c. The snowdrop-tree, from its beautiful blossoms, and the birch and hazel, for the display of their catkins during winter, are well calculated for walks adapted to that season of the year, and should be planted in front of pines, or other evergreens. Such also is the principal situation for flowering shrubs, and no plants can be more showy than the horse-chestnut, common lilac, acacia, guelder-rose, Portugal laurel, holly, bird-cherry, pyrus, mespilus, and laburnum, in similar situations, and for general purposes. In distributing the species of tree in extensive masses, the same general principles of composition must be attended to, which we have pointed out, as far as respects form. The colors and character of the heads of the trees must be connected, and, at the same time, to a certain degree contrasted, in order to produce an artificial and yet harmonious effect.

7210. Whether the new varieties of American and other trees, obtained since the introduction of landscape-gardening, are to be admitted under this style of improvement may be questioned by some. We answer, certainly, unless where the object is the imitation of an ancient residence (fig. 690); and there can be no doubt that where such is the object, exotic trees will destroy part of the allusion; but we do not contend for the revival of the ancient style solely as producing imitations and allusive characters, or on account of its antiquity, but as a distinct mode of gardening. We would therefore not copy its faults or study its defects, but add to its beauties from all the resources furnished by the present improved state of the arts of design, as well as by the continued accession to our stock of trees and shrubs. If however a positive imitation of an ancient residence is intended, then the species of tree should be limited to those used in ancient times, as well as the forms and lines of their disposition.

7211. The manner of disposing the plants is influenced by the same principle of avowed
art; in rows, equidistant masses, in squares, or in quincunx, and in every case so as never to be mistaken for trees or shrubs sprung up accidentally.

7212. Fences. Here the ancient style has a grand advantage over the modern, in which, as far as respects the imitation of nature, all fences are to be considered as temporary, and, therefore, to a certain degree, looked on as nuisances to be afterwards removed. Besides, their irregular and circuitous line is displeasing to many who do not understand ground-plans, with a view to picturesque beauty, when the trees are grown up. But in geometric gardening, fences are to be considered in many cases as objects, and when not regarded in this light, their directions and limits are so minutely pointed out by the determined outline of the plantations, that the eye_acquirees in their situation and use. Fences of any common and economical description are employed to protect the trees of open avenues, open groves, and single open rows. But the more common kind are walls, which in the prominent parts ought to be well built of shaped stone, and substantially finished by raised or flat copings, bearing some relation to the copings of the simpler parapets of the house. The gates necessary in these walls, as well as in some sorts of permanent verdant fences, supply occasion for such architectural forms and lines, as are advantageous in reflecting those of the mansion, and strengthening the prevailing idea of dignity, art, and design. Every sort of fence belonging to the modern style, may be occasionally employed in the ancient; and besides walls, half-sunk walls, and raised mounds with a walk at top, we may enumerate hedges of holly, yew, laurel, and other shrubs, either simple or chequered, by alternate deciduous or evergreen species, varied by arcades and standards, shorn into shapes, or in their natural growth. Hedges of flowering shrubs may also be introduced; of creepers on open palisades; and various others of great beauty may be invented, or are to be found in books on this style of gardening.

7213. Management. In this respect also, the advantage is greatly in favor of the ancient style; for as all operations of pruning and thinning in the other should be done under the eye of the landscape-gardener, so all these operations here may be performed by any laborer; the object being simply to produce a straight, upright, smooth stem, to a certain height according to circumstances, and allow each particular tree to attain its full size. Shearing or clipping is always a mere mechanical operation; plain hedges and close alleys require only a line for a guide; and in the case of arcades or verdant sculpture, there is, or always should be, a frame of trellis-work of correct design to guide the operator. From the comparative brevity of this view which we have taken of planting under the ancient style, the reader will perceive, that we are far from supposing it to take the lead of the natural method to which we now proceed, referring for more particular information to Le Blond, and other French authors; and to Switzer's Ichnographia Rustica.

7214. In planting with a view to natural beauty, the effect of the whole is here also the first and the grand consideration. All planting, as respects the formation of a country-residence, must necessarily be materially influenced by the character and situation of the house, as the capital feature in the composition. To this feature, the leading masses of wood and lawn, answering the end of light and shade in painting, must invite and direct the eye in the general view of the place. (fig. 691.) Each must embrace it on one or on more sides, and diverge from it in masses suitable to its magnitude and the extent of the grounds, and in forms and characters of woody surface, suitable to the natural situation and the expression to be created. If the mansion is on a declivity, the principal light should embrace the front which looks down, rather than those which look up, or on either side. The views from the windows suggest this arrangement, and will point out in every other situation, whether a flat, a hill, or an irregular surface, on which side or sides the leading masses are to have their origin. To determine their magnitude, form, and number, would be impossible, without
a particular case to refer to. To point out their style is sufficient, which must always be irregular like nature; generally stretch along such rising ground as the situation affords; and, like her, always combine a certain degree of uniformity or recognisable shape, even amidst the greatest seeming deviations from this quality of figures. As the house indicates the commencement of the masses, the character of country surrounding the scene of improvement must determine the limits and style of their termination. If the lands are laid out in regular enclosures, bounded by hedges and hedge-rows, fragments of these (fig. 692.) must prevail in the margin of the park; at least in as many places, and to such a degree, as will produce connection; and, if possible, as much farther as will harmonise the scene within, with the country without. If it is entirely or in part surrounded by forest scenery, the termination is easily and completely effected, by attending to the style of wood and species of tree prevailing without, for a moderate distance within the boundary. If bounded by the sea, or a large lake, an abrupt termination will be as natural as it would be formal on the margin of a cultivated surface. Abrupt terminations, however, are often unavoidable, as in examples of villas, where the owner having no demesne, has no control beyond his boundary fence. All that can be done, therefore, in such cases, is, to create as much beauty and interest as possible within the given limits. Where one villa joins another, this sort of isolated abruptness is avoided or lessened; and, in the case of suburban villas (fig. 693.), it is seldom felt as any deformity, though, even here, connection and general harmony with what is exterior, will add beauty to what is within.

7215. The details of planting in this style have already been given at length in the preceding book.

SECT. III. Of operating with Water.

7216. Water is a material of so captivating and interesting a description in the different characters in which it occurs in nature, that no view can be reckoned complete in which it does not compose a feature. It forms a part of every garden in the ancient style, in the various artificial characters which it there assumes of oblong canals, ponds, basins, cascades, and jeux-d'eau (fig. 694.); and in modern improvement, such is the
value attached to its effect, that no place is deemed perfect without a river or lake; and such the indiscriminate desire of obtaining them, that nature has been too frequently dis-regarded in their form and situation. Of the characters which water assumed under the geometric style, we can only observe, that their names convey, in a great degree, an idea of the forms. Their situations were near the mansion; and their marginal accompaniments of masonry, turf walks, and hedges, were determined by the architectural forms and lines of the capital feature in the scene. The choice, from the most intricate and curious fountains to the plain oblong canal, depended on the splendor of the general design; very little on natural situation. The supply was generally obtained from some concealed reservoir.

7217. To imitate lakes, rivers, or rills, and their accompaniments, is the object of landscape-gardening; and of each of these natural characters we shall remark the leading circumstances in the originals and the imitations. All water is either running or stagnant. Lakes, ponds, and pools, are of the latter class; rivers, rivulets, and rills, of the former description. In certain situations, lakes may be created where their supply is moderate; rivers and rills only when it is abundant. Both characters, when they exist in nature, may be improved by studying the natural characteristics of each species.

7218. Situation, relatively to the character of the ground's surface, is the first consideration respecting water, in whatever form it may appear. No situation in which this material may be supposed to exist and expand itself into a body, can be truly natural, that is not a vale, plain, or hollow. Mountain streams are out of the question; and small lakes or pools, in hollows or elevated grounds, are more to be considered as accidental than as general nature. Even artificial lakes or rivers on a considerable scale, to be natural must either be, or seem to be, situated in the lowest part of the landscape then under the eye. If otherwise, if placed on the side of a declivity over which the eye can range at the same time, it may be attractive to a stranger at first view; but the want of truth or fidelity to the thing to be imitated, will soon bring on an increasing aversion in the mind of genuine taste.

7219. Ponds in different levels, seen in the same view, are very objectionable on this principle. The little beauty they display as spots, ill compensates for the want of propriety; and the leading idea which they suggest, is a question between their present situation and their non-existence. The choice, therefore, as to the situation of water, must ever depend more on natural circumstances than proximity to the mansion. Is then all water to be excluded that is not in the lower grounds? We have no hesitation in answering this question in the affirmative, so far as respects the principal views, and when a lower level than that in which the water is proposed to be placed is seen in the same view. But in respect to recluse scenes, which Addison compares to episodes to the general design, we would admit, and even copy the ponds on the sides or even tops of hills, which may be designated accidental beauties of nature. In confined spots they are often a very great ornament (fig. 695); as a proof of which, we have only to observe some of the suburban villas round the metropolis, where a small piece of water often comes in between the house and the public road with the happiest effect.

7220. A beautiful lake, or part of a circuitous body of water, considered as a whole, will be found to exhibit a form, characterised by breadth rather than length; by that degree of regularity in its outline as a whole, which confers that, which, in common language, is called shape; and by that irregularity in the parts of this outline, which produces variety and intricacy. Supposing the situation to be fixed on for the imitation of a lake (fig. 696), the artist is to consider the broadest and most circuitous hollow as his principal mass or breadth of water, and which he will extend or diminish according to the extent of aquatic views the place may require. From this he
may continue a chain of connected masses of water, or lakes of different magnitudes and shapes, in part suggested by the character of the ground, in part by the facilities of planting near them, and in part by his own views of propriety and beauty. The outline of the plan of the lake is to be varied by the contrasted position of bays, inlets, and smaller indentations, on the same principles which we suggested for varying a mass of wood. To the irregularity of outlines so produced, islands and aits (fig. 697.) may be added on the same principle, and for the same objects as thickets and groups. This will complete the character and beauty of the plan of the water.

7221. But the grand effect of water in landscape, depends on wood as its accompaniment. The variety and intricacy of outline, the reflection of forms and colors, the shady recesses and flickering lines of light, all depend on trees. These are not to be sparingly or indiscriminately scattered around the margin, but liberally in some places, for the sake of a contrasted mass of grateful color or shade, to relieve the brilliancy of the water; and with discrimination everywhere to mark the beauties, and heighten the variety of the outline, without destroying breadth of effect, or a whole, either as respects the water alone, or the entire residence.

7222. The marginal banks of water in nature, are tame or bold, gravelly or sedgy, stony or rocky, according to the character of the surrounding ground. Art, therefore, must imitate each in its proper place, not always by a studious picturesque arrangement of the marginal accompaniments in each case, but by excavating the ground-work, planting the trees and shrubs, and leaving the rest to the motion of the waves of the water. After the effects of one winter, stones or gravel may be deposited in spots suitable for stony or gravelly shores. But to enter into this, and many other circumstances in the imitation of lakes, would exceed the proper limits. We add two cautions: the first is, in all cases of the beautiful picturesque, so to arrange by puddling and under-draining, that a marshy appearance may not surround the lake; and that rushes, and such aquatic plants, may not extend farther than a few feet or yards from the margin of the water. The other respects islands, which are the greatest ornaments to lakes. But that island which is placed in the centre, or in any situation where it does not connect with other islands, or with the shore, so as to form part of a prominence or recess, is injurious to the effect of the whole inversely as its beauty, when properly placed.

7223. Rivers and rills, we have said, are rather to be improved than created; for we cannot sympathise with that taste which directs the mimicry of so noble a character as a river, or is satisfied with a nearly stagnated rill. We do not consider the river at Blenheim as an exception, because that piece of water was formed by widening a considerable brook. We allude to those wavy serpentine canals, which are never mistaken for natural scenes, and, in almost every case, might be advantageously exchanged for a lake. A rill, however, may have its course rendered more varied, may be expanded at proper places into regular shapes, and all the alterations accounted for and harmonised by planting. (fig. 698.)
rivers and rills will readily suggest themselves. Cascades and waterfalls may sometimes be created; and the occasional expansion of natural brooks into pools, affords a fine hint for imitation, when this form of water comes within a scene of improvement. One of the greatest improvements that can be made in many places laid out in Brown's time, and subsequently, consists in widening in some places, and varying the margin in others, of those tame serpentine canals, then so much in fashion. By this means, and by adding islands and trees, they may often, without deranging the place as to other details, be rendered highly beautiful at a moderate expense. (fig. 699.)

A waterfall, or cascade, is an obvious improvement where a running stream passes through a demesne (fig. 700), and is to be formed by first constructing a bank of masonry, presenting an inclined plane (a) to the current, and rendering it impervious to water by puddling (1720.) or the use of proper cements, and next varying the ridge (b) and under side (c), with fragments of rock, so chosen and placed, as not to present a character foreign to what nature may be supposed to have produced there. The adjoining ground generally requires to be raised at such scenes, but may generally be harmonised by plantation.

Where running water is conducted in forms belonging to the geometric style of gardening, waterfalls and cascades are constructed in the form of crescents, flights of steps, or wavy slopes; all which have excellent effects of their kind when appropriately introduced, as at Chatsworth, Hatton, and many other places.

A natural stream may sometimes be improved by altering its direction, and bringing it through a more interesting part of the grounds; and we have known an admirable effect produced by bringing a distant river close to the house, even so much so as to wash the base of its terrace-wall. (fig. 701.)
7228. The imitation of rocks forms no part of the geometric style of gardening, and are a material of the natural style, equally unsuitable to be created. But though rocks cannot readily be imitated, their expression may sometimes be heightened when desirable, and concealed when disagreeable.

7229. The character of rocks may be savage, terrific, sublime, picturesque, or fantastic. By attending to the forms of the milder characters, and their connection with ground and trees, we shall discover whether, and to what extent, they may be improved. Savage rocks are too inhospitable to be permanently admitted, in any extent, near the eye. All rocks convey something of this idea that are not accompanied by vegetation; and, therefore, planting among or near them is, in every case, an improvement where trees do not exist. All rocks are expressive of dignity; those eminently so, are not greatly varied by projections from their surface: their beauty is to be augmented, either by increasing their surface in height or depth, or by connecting it if too scattered. The removal of a few feet of earth, or part of the bushes or trees from the bottom of a precipice or ridge, and the emplacement of a line of wood along its summit, will increase its real and apparent height; a similar process, with respect to the sides, will add to the idea of stability and continuation. If the parts are too much scattered, a few trees placed before, or bushes or creepers planted in the intervals between the parts, will connect them, and give the idea of a whole, partly concealed. But in this case, a considerable breadth of surface is necessary, at least in one place, otherwise dignity must give way to picturesque beauty. But the least indications of rocks that are not very fantastic in their form, even including such whose chief expression is picturesque beauty, are, to a certain degree, expressive of dignity. The slightest indication of a stratum or ledge appearing above the surface, conveys something of this idea, and ought not to be neglected. When they are discovered by alterations in the ground with a view to the formation of roads, fences, and water, or to the erection of buildings, occasional advantage may be taken of their appearance. A road across a declivity may be accompanied by a ledge of rocks instead of a bank of earth. Grounds which are broken and picturesque, will display a more sufficient reason for the appearance. The walls of a terrace evidently in part founded on a rock, will give an idea of dryness, dignity, and security to the house; and the margin of a stream displaying even large stones, increases the idea of impetuosity; or, in lakes, of the action of water in washing away the earth. Among imitations of wild scenery, detached stones heighten the illusion, and carry back the mind to the aboriginal state of the country. Loose or detached fragments of rocks may often aid the effect of real or supposed masses. The appearance of a large rude stone near a wooded steep, unless of one evidently rounded by water or art, always leads the mind to the larger mass up the acclivity from which it has been broken and rolled down; if partly sunk in the ground, and concealed by vegetation, the fertility of the imagination considers them as parts of magnitudes which lie buried under the surface. All this, however, can only be successfully accomplished in a country which, by the character of its general surface, does not preclude the idea of rocks. On a flat or a champaign country, the want of truth, or seeming truth, would render them disagreeable; and, indeed, did rocks exist in such a landscape, they should be hidden rather than displayed, unless of such extraordinary magnitude and effect, as to form an exception to general principles.

7230. The judicious distribution of stones, in situations where they are not evidently foreign to the character of soil and surface, may greatly heighten wildness and picturesque beauty. (fig. 702.) Every thing, however, will depend on the manner in which this is done; they must not be merely laid down at random on the surface (a), or formally joined together (b), or merely connected, which, however, is better (c); but grouped with taste (d), and partially concealed by vegetation and sunk in the soil. (f, g).

7231. Fantastic stones (fig. 703. a) should be avoided in all cases, unless in some peculiar scene; and where there are already indications of stratified or regular masses of rock (b), it can never appear natural to place near them round, water-worn stones (c). Where angular and laminated stones are near; or where
such as can be quanried in forms suitable for building may be procured, grand effects may be produced; either by using them in forming imitations of nature, or by combining them in a mixed style of artificial form and natural conglomeration. (fig. 704.)

Sect. V. Buildings.

7232. Buildings, as materials of scenery, are entirely under the power of man; and, from that circumstance, were carried to an unwarrantable excess in the decline of the ancient, and the infancy of the modern style. Improvements on ground are forgotten by their effect; that of planting may be accounted too distant or too slow by ordinary minds; but a building is complete the moment it is finished. It affords immediate satisfaction to the owner; and being known as a costly object, full credit is given to him for the expense incurred. Thus wealth, confiding in its powers, multiplied garden-buildings to an excess, which ended in creating a disgust, still existing, in some degree, at their appearance in improved scenery. Before proceeding further, it may be proper to offer some remarks on the style or architecture of buildings.

7233. It is a common error to consider nothing as architecture but what is Grecian; to fancy that all architecture must have what are called orders; and to consider the Gothic, Chinese, or Hindoo modes of building, as mere barbarous compositions. But nothing can be more unphilosophical than this mode of viewing the subject; and it may just as well be said that there is no true language in the world but the Greek; that every language ought to correspond with it in the tenses and moods of the verbs; and that every other mode of speech is mere jargon. A style of building, and mode of oral communication, must have a sufficient claim to be considered as complete, when they answer the purposes for which they are intended; and, applying this principle to the architecture and language of different countries, we shall find that each is complete relatively to those countries. That any style of building, or any language can be universally suitable, is to suppose that the same climate and the same degree of civilisation prevails over the whole globe. Thus, as there are different languages, and different manners and customs, so there are different styles of architecture; and though we may prefer the Grecian, as having been used by the most refined nations of antiquity, let us not hastily reject every other style as devoid of congruity, or unsuitable for being applied to constructions of use or beauty.

7234. The origin of the different styles of architecture are usually traced to imitations of temporary structures formed of timber or of rough trees; and thus the Grecian column, with its capital ornamented with foliage, has been called an imitation of the trunk of a palm, with the petioles of its recently dropped leaves still adhering; the Gothic arches and tracery have been likened to wicker-work, or the intersecting branches of an avenue; and the Chinese style to the imitation of a tent supported by bamboo. But the imitation of nature is the last thing that occurs in the progress of improvement; and though the above opinions may not be without their use as a sort of hypothesis for composition; yet it appears much more probable that styles of building have taken their origin, jointly from the materials the country afforded, and the wants of the people. According to this hypothesis, the Grecian may be considered as founded on the use of planks of stone, in the same way as beams of timber (fig. 705. a); the Gothic, by the use of small stones, held together by their position (b); and the Hindoo, by the use of small stones, held together by superincumbent weight (c). The Doric temple (fig. 706.) is easily traced in this way to its prototype of wood; but though the idea be supported by the authority of Vitruvius, it should never be considered as anything more than mere conjecture.

7235. The progress which architecture has made in Britain, in modern times, is matter of greater certainty; and Repton, with his usual taste, has furnished an ingenious
the partiality of individuals, in affixing different degrees of importance to each consideration. Hence it is obvious, that there can be no danger of sameness in any two designs conducted on principles thus established; since in every different situation some one or more of these considerations must preponderate; and the most rational decision will result from a combined view of all the separate advantages or disadvantages to be foreseen from each. It was the custom of former times, in the choice of domestic situations, to let comfort and convenience prevail over every other consideration. Thus the ancient baronial castles were built on the summits of hills, in times when defence and security suggested the necessity of placing them there; and difficulty of access was a recommendation: but when this necessity no longer existed, (as mankind are always apt to fly from one extreme to the other,) houses were universally erected in the lowest situations, with a probable design to avoid those inconveniences to which lofty positions had been subject; hence the frequent sites of many large mansions, and particularly abbeys and monasteries, the residence of persons who were willing to sacrifice the beauty of prospect for the more solid and permanent advantages of habitable convenience; amongst which, shelter from wind, and a supply of water for store fishponds, were predominant considerations." (Enquiry, &c. p. 83.)

7251. In hilly countries, or in any country where the surface is varied, the choice is neither made in the bottoms (fig. 715. a), nor on the summits of the eminences (c), but generally on the south-east side of the latter (b), on a raised platform, the rising grounds behind being planted both for effect and shelter.

7252. The field of vision, or portion of landscape which the eye will comprehend, is a circumstance frequently mistaken in fixing a situation for a house; since a view seen from the windows of an apartment will materially differ from the same view seen in the open air. Much evidently depends on the thickness of the walls (fig. 716. c), the width of the windows (a), and the distance of the spectator from the aperture. Near the centre of the room (b), the spectator will not enjoy above 20 or 30 degrees of vision; but close to the window (c) his eye will take in from 70 to 100 degrees. Hence, to obtain as much of the view from a room as possible, there should not only be windows on two sides of a room, but one in the angle, or an oblique or bow-window on each side, instead of the common form. (Obs. on Landscape Gardening, p. 24.)

7253. The aspect of the principal rooms deserves particular attention in every case, and most so in bleak or exposed situations. The south-east is most commonly the best for Britain (fig. 717.); and the south, and due east, the next best. The south-west, Repton considers the worst, because from that quarter it rains oftener than from any other; and the windows are dimmed, and the views obstructed, by the slightest shower, which will not be perceptible in the windows facing the south or east. A north aspect is gloomy, because deprived of sunshine; but it deserves to be remarked, that woods and other verdant objects look best when viewed from rooms so placed, because all plants are most luxuriant on the side next the sun. "The aspect due east," he considers, "nearly as bad as the north, because there the sun only shines while we are in bed; and the aspect due west is intolerable, from the excess of sun dazzling the eye through the greatest part of the day. From hence we may conclude, that a square house, placed with its fronts duly opposite to the cardinal points, will have one good and three bad aspects." (Fragments on Landscape Gardening, &c. p. 108.)

7254. A mansion for the country, if a mere square or oblong, will thus be deficient in point of aspect, and certainly in picturesque beauty, or variety of external forms, lights, and shades. An irregular plan, composed with a combined view to the situation, distant views, best aspects to the principal rooms, effect from different distant points, and as forming a whole with the groups of domestic offices and other architectural appendages or erections, will therefore be the best; and as the genius of the Gothic style of architecture is better adapted for this irregularity than the simplicity of the Grecian, or the regularity of the Roman styles, it has been justly considered the best for country-residences. Another advantage of an irregular style is, that it readily admits of additions in almost any direction.
7255. Convenience, as well as effect, require that every house ought to have an entrance-front, and a garden-front; and, in general cases, neither the latter, nor the views from the principal rooms, should be seen fully and completely, but from the windows and garden-scenery. Not to attend to this, is to destroy their contrasted effect, and cloy the appetite by disclosing all, or the greatest part of the beauties at once. The landscape which forms the back ground to a mansion, the trees which group with it, and the architectural terrace which forms its base, are to be considered as its accompaniments, and influenced more or less by its style. The classic pine and cedar should accompany the Greek and Roman architecture; and the hardy fir, the oak, or the lofty ash, the baronial castle.

7256. Terrace and conservatory. We observed, when treating of ground, and under the ancient style, that the design of the terrace must be jointly influenced by the magnitude and style of the house, the views from its windows, (that is, from the eye of a person seated in the middle of the principal rooms,) and the views of the house from a distance. In almost every case, more or less of architectural form will enter into these compositions. The level or levels will be supported partly by grassy slopes, but chiefly by stone walls, harmonising with the lines and forms of the house. These, in the Gothic style, may be furnished by battlements, gateways, oriels, pinnacles, &c.; or, on a very great scale, watch-towers may form very picturesque, characteristic, and useful additions. The Grecian style may, in like manner, be finished by parapets, balustrades, and other Roman appendages.

7257. The breadth of terraces, and their height relatively to the level of the floor of the living-rooms, must depend jointly on the height of the floor of the living-rooms and the surface of the grounds or country to be seen over them. Too broad or too high a terrace will both have the effect of foreshortening a lawn with a declining surface, or concealing a near valley. The safest mode in doubtful cases is, not to form this appendage till after the principal floor is laid, and then to determine the details of the terrace by trial and correction.

7258. Narrow terraces are entirely occupied as promenades, and may be either gravelled or paved; and different levels, when they exist, connected by inclined planes or flights of steps. Where the breadth is more than is requisite for walks, the borders may be kept in turf with groups or marginal strips of flowers and low shrubs. In some cases, the terrace-walls may be so extended as to enclose ground sufficient for a level plot to be used as a bowling-green or a flower-garden. These are generally connected with one of the living-rooms or the conservatory, and to the latter is frequently joined an aviary and the entire range of botanic stoves. Or, the aviary may be made an elegant detached building, so placed as to group with the house and other surrounding objects. An elegant structure of this sort (fig.718) was designed by Repton for the grounds of the Pavilion at Brighton.

7259. The flower-garden should join both the conservatory and terrace; and, where the botanic stoves do not join the conservatory and the house, they, and also the aviary and other appropriate buildings and decorations, should be placed here. (See 6076, and 6161.)

7260. The kitchen-garden should be placed near to, and connected with the flower-garden, with concealed entrances and roads leading to the domestic offices for culinary purposes, and to the stables and farm-buildings for manure. (See 2382.)

7261. The situation of the orchard should, all other circumstances being suitable, be near to the kitchen-garden; and between them may be very properly placed the gardener's house, connected with the furnace, sheds, fruit-rooms, &c. (See 2527.)

7262. The lawn, or that breadth of mown turf formed in front of, or extending in different directions from, the garden-front of the house, is, in the geometric style, varied by architectural forms, levels, and slopes; and in the modern by a picturesque or painter-like disposition of groups, placed so as to connect with the leading masses, and throw the lawn into an agreeable shape or shapes. In very small villas the lawn may embrace the garden or principal front of the house, without the intervention of terrace-scenery, and may be separated from the park, or park-like field, by a light wire fence; but in more extensive scenes it should embrace a terrace, or some avowedly artificial architectural basis to the mansion, and a sunk wall, as a distant separation, will be more dignified and permanent than any iron fence. The park may come close up to the terrace-garden, especially in a flat situation, or where the breadth of the terrace is considerable.

7263. The shrubbery generally connects the house and flower-gardens, and forms, strictly speaking, a part of the pleasure-ground scenery. It is a scene in which the object is to arrange a collection of foreign trees and shrubs in a dry border, generally on the north side of a walk, or in dug groups and patches. One very principal consideration is, to connect, partly in appearance only, the dug patches. The distinct unconnected obstruction of such scenes is justly reprobated by Price, who gives excellent in-
structions for creating the beautiful picturesque among dug groups, and preserving all the polish and appearance of high keeping with the most delicate culture of the plants. (See 6187.)

7264. The pleasure-ground is a term applied generally to the kept ground and walks of a residence. Sometimes the walk merely passes, in a winding direction, through glades and groups of common scenery, kept polished by the scythe, and from whence cattle, &c. are excluded. At other times it includes a part of, or all the scenes above mentioned; and may include several others, as verdant amphitheatres, labyrinths, (fig. 719.) a Linnaean, Jussieuan, American, French, or Dutch flower-garden, a garden of native, rock, mountain, or aquatic plants, picturesque flower-garden, or a Chinese garden, exhibiting only plants in flower, inserted in the ground, and removed to make room for others when the blossom begins to fade, &c.

7265. The park is a space devoted to the growth of timber, pasturage for deer, cattle, and sheep, and for adding grandeur and dignity to the mansion. On its extent and beauty, and on the magnitude and architectural design of the house, chiefly depend the reputation and character of the residence. In the geometric style, the more distant or concealed parts were subdivided into fields, surrounded by broad stripes or double rows, enclosed in walls or hedges, and the nearer parts were chiefly covered with wood, enclosing regular surfaces of pasturage. In the modern style, the scenery of a park is intended to resemble that of a scattered forest, the more polished glades and regular shapes of lawn being near the house, and the rougher parts towards the extremities. The paddocks or small enclosures are generally placed between the family stables and the farm, and form a sort of intermediate character.

7266. The farm, or that portion of agricultural surface, retained in the hands of the owner for private cultivation, was, in both styles, placed without, but adjoining the park; and when circumstances admitted, near to the paddocks. In some cases, on a moderate scale, part of the park constitutes the whole, or a part of the farm, and is kept in aration. The trees in this cultivated space are arranged in natural-like masses, so as to give the idea of part of a forest-scene subjected to the plough. When the park is extensive and truly forest-like, the effect of the whole is much improved by the contrast, and recalls to mind those charming scenes in the woody districts of Germany, where cultivation smiles in the glades and recesses of eternal forests.

7267. The riding, or drive, is a road indicated rather than formed, which passes through the most interesting and distant parts of a residence not seen in detail from the walks, and as far into the adjoining lands of wilderness or cultivation, as the property of the owner extends. It is also frequently conducted as much farther as the disposition of adjoining proprietors permits, or the general face of the country renders desirable.

7268. Original arrangement. Though the above arrangement of the component parts of a residence will be found, in general, the most convenient on a flat surface, or one gently varied, we are far from recommending its universal adoption. Situations are always fertile in suggesting new ideas, which

"Start even from difficulties, strike from chance;"

and a mind already stored with a knowledge of every part of the subject, works from principles, and fortuitous suggestions, rather than models. We would rather see an original idea attempted than the most beautiful arrangement imitated.

CHAP. IV.

Of the Union of the constituent Scenes in forming Gardens or Residences of particular Characters; and of laying out Public Gardens.

7269. To complete a country-residence is the end of all landscape-gardening, whether imitative or geometric. In the preceding chapter we have given a general idea of the parts or scenes, and their connection, which enter into a complete residence of the first order. We have now to notice their arrangements in different gradations of residences
and these, we must previously acknowledge, are so intimately blended, that we hardly know how to separate them, and give a distinctive character to each; every country-gentleman, from the occupier of the palace to the cottage, adopting such luxuriant scenes as suit his particular taste, without reference to any thing but his own desires; and this happy circumstance contributes, perhaps, as much as the difference of situations, to the variety in the beauty and style of British country-residences. Mansions, villas, temporary residences, cottages, and public gardens, may be said to include the leading distinctions. Public gardens are much less various than private ones, because there are fewer publics than individuals.

**Sect. I. On laying out Private Gardens, or Residences.**

7270. The specific distinctions of private residences may be considered as the mansion and demesne, the villa, the farm, the temporary residence, and the cottage; but each of these branches out into a number of subspecies and varieties.

7271. The mansion and demesne. The characteristic of the mansion and demesne, is the demesne or surrounding lands in tenancy. Any residence of which the dwelling-house is of a higher character than that of the mansion and demesne, as the castle, abbey, and palace, has the same general arrangement in the grounds, and differs chiefly in extent, and in the arrangements of the courts and other exterior appendages of the house.

7272. As a specimen of this style, we shall give the arrangement at Michel Grove in Sussex, the residence of R. Walker, Esq. from the works of Repton:

7273. In determining the situation for a large house in the country, there are other circumstances to be considered besides the fences and appendages immediately contiguous. These have so often occurred, that I have established in imagination certain positions for each, which I have never found so capable of being realised as at Michel Grove.

7274. I would place the house, with the principal front, towards the south-east.

7275. I would place the offices behind the house; but as they occupy much more space, they will of course spread wider than the front. I would place the stables near the offices. I would place the kitchen-garden near the stables. I would put the home-farm buildings at rather a greater distance from the house; but these several objects should be so connected by back roads as to be easily accessible.

7276. I would bring the park to the very front of the house.

7277. I would keep the farm or land in tillage, whether for use or for experiment, behind the house; I would make the dressed pleasure-grounds to the right and left of the house, in places which would screen the unsightly appendages, and form a natural division between the park and the farm, with walks communicating to the garden and the farm.

7278. The villa may be nothing more than a park with a house of smaller size than that of the mansion and demesne, surrounded by a pleasure-ground, and with the usual gardens. Moderate extent and proximity to other villas, constitute the characteristic of this class of residences; but though adjoining lands are not necessary to the character, they do not, where they exist, change it, unless their extent be considerable. Two villas joined together often mutually aid each other in effect, especially as to water and trees. (fig. 720.)

7279. The villa farm. A villa being originally a farm-house, we think that the Roman arrangement, in which the farm-offices were joined to, or at least so near, as to form with it and the domestic offices one group of buildings, might be adopted as the characteristic distinction of this class of residences. The farm-buildings should, in that case, be dignified with more architectural design than when placed at a distance; but
still in due subordination to the man-
sion. Instead of deer, sheep may
graze the park on the garden-front,
separated from the house by an archi-
technical barrier, or in some situations,
with a platform of gravel, and walks
and knots of flowers. A glacis of
turf, with a light fence below the
slope, will be sufficient protection
from sheep or cattle, and not impede
the view of the lawn from the win-
dows. The entrance-front may be
approached through grass fields, not
separated with common hedges, but
with picturesque fences (fig. 721.)
in the modern, and double hedges
and slips of planting in the geometric
style. All or any part of the other
constituent parts of a mansion and
demesne residence, such as hot-houses,
gardens, orchards, pleasure-grounds,
&c. may or may not be added, ac-
cording to its extent, and the parti-
cular taste of the proprietor.

7280. The ferme orne differs from a common farm in having a better dwelling-house,
nearer approach, and one partly or entirely distinct from that which leads to the offices.
It also differs as to the hedges, which are allowed to grow wild and irregular (fig. 722.),
and are bordered on each side by a broad green drive, and sometimes by a gravel-walk
and shrubs. It differs from a villa farm in having no park. A dry hilly soil is best

suited for this description of residence, of which there are some fine examples in Surrey,
Kent, and the Isle of Wight.

7281. Temporary residences, as marine villas, sporting or shooting boxes, seldom con-
tain much land attached. No hot-houses, and but little pleasure-ground is here required. What land there may be, should be applied to use rather than to beauty. Speaking of hunting-boxes, Marshall observes "a suit of paddocks should be seen from the house; and if a view of distant covers can be caught, the back ground will be complete. The stable, the kennel, the leaping-bar, are the appendages, in the construction of which simplicity, substantialness, and conveniency should prevail."

7282. A cottage ornée, we think, might be characterised by the garden-front opening into a picturesque orchard; or a lawn, varied by groups of fruit-trees, instead of a lawn or park planted with forest trees. It may contain any part of the scenes of the villa, at the will of the owner. If the situation of the house is elevated, so as to give a view from the principal rooms of a great part of the farm, it will be the more desirable. A desirable foundation for this improvement is an old English farmhouse; by adding to which one or two principal rooms, a very interesting group may be formed at little expense.

7283. Cottage en verger. An agreeable variety of this species sometimes adopted in France, consists in surrounding an enclosed space of one or two acres, with an irregular strip of walnut, cherry, chestnut, and other tall-growing trees (fig. 722. a) which produce both fruit and timber; and then planting the interior space (b) with the finer sorts of fruit-trees, especially pears and plums, as standards, on turf. Winding walks are led through the whole, and groups of flowers and kitchen-vegetables introduced.

7284. The citizen's villa (fig. 723.) is a spot of one or more acres laid out in lawn and shrubbery, but without a kitchen-garden. As the space contained is very limited, and often under an acre, only the most select trees, shrubs, and flowers should be employed; and great part of the trees and shrubs should be evergreens. Seats and other decorations may be introduced, of the most select designs, and best workmanship; and what is of the last consequence, none but a good gardener should be employed in order to preserve the whole in the highest order and keeping, at every season of the year. Gardens or residences of this sort are almost peculiar to the neighborhood of London; and the occupant procures his culinary productions and fruits cheaper and better than he can grow them, from that first of all gardens, Covent-garden.

7285. The suburban villa (fig. 724.) is of limited extent, but contains a small kitchen-garden and stables, with a field planted either in the ancient style (a), or modern style (b); with a neat lawn, and groups of flowers (c). Such villas are occupied more by professional men and artists, than by the lesser merchants and rich tradesmen, who (those of the metropolis at least) prefer the citizen's villa. When two or more of such villas can be formed adjoining each other, the happiest effects may be produced if
their owners act in concert at their first planting; and a sort of community of scenery may be enjoyed, without lessening individual privacy and comfort. On the contrary, a gain might result to each proprietor rather than otherwise; for if two villas, adjoining each other, are laid out in the modern style, then by placing the masses of wood of the one, against the masses of the other, less ground would require to be occupied in plantation by each. Office-buildings might be placed against, or near office-buildings, so as to be shut out, or partially concealed with less than the usual quantity of trees, and so on. In the ancient style, avenues and vistas might be contrived to pass through each other's grounds, and the ornamental objects which formed their termination, serving both parties, only half the usual number would require to be erected by each.

7286. The suburban house (fig. 725.) is a large commodious dwelling, in a village-like collection of houses, or streets, on the outskirts of the metropolis, or of large towns; and occupied as the constant residence of wealthy professional men or mer chants. It has a carriage-entrance to the house and stables in front, and a small kitchen-garden behind.

7287. The house with carriage-entrance (fig. 726.) occurs very commonly in the suburban streets of large cities; it contains a small garden behind, not however sufficient to employ a gardener; and it is without stable or coach-house; the fore-court is varied by shrubs and a few trees, and the central circle of turf, ornamented with baskets of flowers or roses; and in the middle a statue, sundial, fountain, pond, or a cedar, or other evergreen tree.

7288. The house with covered entrance (fig. 727.) is similarly situated to the other, but generally further from town, to and from which the occupant passes by the local public conveyances. It contains a garden-court before, and a garden behind the house, like the other; but the former is entered by a porch (a), connected with the house by means of a glass or opaque roofed passage (b); and along the front of the house is an open veranda (c, c) communicating with a vestibule (d). This sort of suburban house is well suited for invalids, who may take exercise, and enjoy the plants under the glass roofs in rainy weather.

7289. The house and conservatory (fig. 728.) is similarly situated to the last, with one or two wings (a and b), as conservatories; or, the one a conservatory, and the other a botanic stove, or a vineyard. These communicate with the two principal living-rooms, and also with the fore-court (c); the latter entrance is that made use of by the gardener. Heat is supplied from the under-ground offices of the house; and if the latter is heated by hot air, in Sylvester's excellent manner, or by the more simple operation of steam, it will be accomplished so much the more readily.
and effectually. They may be also lighted up by gas, if there is a public gasometer in the neighborhood.

7290. The house and flower-garden entrance (fig. 729.) requires a more airy situation than either of the three last varieties; and is generally situated in some road or street, a mile or two from town, or in some suburban hamlet. The flowers may be variously arranged, and may be either florists' flowers or herbaceous perennials, with a mixture of dwarf ornamental shrubs. A very complete mode is to grow the flowers in the garden behind the house, and bring them to the front as they come in flower. This sort of residence is well suited for retired tradesmen, who act as their own gardeners; and some fine examples are to be found at Hammersmith, Hampstead, and round Manchester. The French and Dutch, and also the Germans, excel in this kind of garden, and produce the most pleasing effects by a judicious combination of very few species of flowers. They take care to select such as are showy, of brilliant and distinct simple colors, as white and scarlet lilies, red and white roses, nasturtium, candy-tuft, daisy, larkspur, &c. They admit few yellows, or small scattered flowering plants; but study to have masses of the same colors and forms, contrasted by different colors also in masses. There are many fine gardens of this sort in Picardy and the Netherlands, and some in Hanover.

7291. The house and French parterre (fig. 730.) can hardly be considered a distinct variety from the last; though it differs in this, that the front garden of the latter contains turf around the flower-compartments, whereas the former is composed entirely of earth, and gravel, edged with box, or some other plant.

7292. The common front garden (fig. 731.) is a variety so well known as to require no description; but, like the six preceding varieties, it is introduced here chiefly to suggest, that these humble scenes may be greatly improved in design, and also in cultivation and keeping. There is little danger of the gardens of the wealthy being neglected; but it is of great importance to the advancement of gardening, that the art should be displayed to as great perfection as possible in those gardens which are most universal; which are continually under the eye of a large city population; seen by the whole country-inhabitants, when they visit the towns; and which chiefly come under the eye of foreigners.
7293. The farmer's garden should not be placed adjoining the rick-yard, on account of the straw liable to be blown into it; and should be well enclosed to exclude poultry, pigs, and other domestic animals. Supposing the farm-buildings to occupy three sides of a square, and the farm-house to be placed in the middle of the south side, and the rick-yard to be placed beyond the north side; then the kitchen-garden may be placed adjoining the east or west side of the square; the grass-orchard, which may also be the drying-ground, and area for rearing young poultry, on the opposite and corresponding side; and a small flower-garden may serve as an entrance-court to the farm-house. But in the case of farmeries on a larger scale, where the house is detached from the court of offices, the three gardens should be united with a small portion of lawn, and a pond, so as to form about an acre (more or less, according to circumstances), of garden and pleasure-ground round the house. (fig. 662.) The part destined for the growth of culinary vegetables should be laid out in right-lined plots and borders; the orchard-trees planted in rows or quincunx; and the flowers and flowering shrubs arranged in groups or beds on turf. The most useful and prolific fruit-trees should be chosen; including some plants of hops, and one or two walnut or chestnut trees in the exposed side of the orchard, if the climate is such as will ripen their fruits. No class of men have it in their power to form and cultivate a garden at less expense than that of the farmer; but unfortunately few farmers have a taste for the subject; perhaps, because gardening is not sufficiently contrasted to agriculture, to afford the farmer that sort of relief sought for in recreative and pleasurable pursuits.

7294. The laborers' cottage and garden. This may be reckoned too humble a country-residence for the consideration of the landscape-gardener; but we conceive it to be of very great importance to the general good, that these should be improved, and their inhabitants ameliorated. What we shall advance is founded on the principle, that whatever renders the cottager more comfortable and happy at home, will render him a better servant and subject, and in every respect a more valuable member of society. Besides, one of the most constantly occurring objects in the country is the laborer's cottage, whether detached by the road-side, or grouped in hamlets and villages; and therefore to render such buildings and their scenery more ornamental must, independently of every other consideration, be a very laudable object.

7295. The accommodation contained in the cottage, and the size of the garden, should, no doubt, be regulated by the family of the cottager, and the facilities afforded him by his line of employment to live well, or bring up a large family, &c. But we shall take the lowest case that can occur, and state what we consider to be the minimum of accommodation, which a humane and reasonable employer in England would wish to be enjoyed by his serving laborer, even if he had no other family than his wife.

7296. The whole space to be enclosed, including the garden and the site of the house, cannot be less than one eighth part of a statute acre. The cottage should, if possible, be placed in the centre, fronting the south-east, by which means, if it be a square or a parallelogram, the sun will shine on each of the four sides a part of every day in the year. Its floor should be raised two steps above the level of the garden; its principal windows to the south-east. A gutter should be placed under the eaves, to prevent the ground, at the back of the building, from receiving extreme moisture, and thus rendering the interior damp and unwholesome. The cottage should consist of the following parts:

7297. A porch to throw off the rain from the steps of the door, and prevent it from being blown in by the wind. On the smallest scale, two broad boards, or two slates or flag-stones, placed pediment-wise over the door will answer.

7298. A lobby, broad passage, or other space inside the door, to contain lumber, fuel, garden-tools, and to serve as a place for washing, or working at coarse work, &c.

7299. A living and living-room entered by the lobby or outer room; the fireplace, with an oven and small boiler, both included in a cast-iron grate.

7300. A sleeping-room over the living-room, and entered by a stair from the lobby or outer room.

7301. A garret, or children or lodger's sleeping-room, or small room for any purpose, over the lobby or outer room.

7302. A pantry, taken off the lobby, with a small window to the north-west.

7303. A closet, for utensils and articles used in the living-room, taken off that room, with a window to the north-west or south-east.

7304. A scullery, forming part of the garret over the lobby, and entered by a poultry-ladder, placed against a small opening near the bottom of the outer wall.

7305. In the garden should be a well, with a pump, if deep; unless some other source of good water is near.

7306. A water-closet placed in a hidden part of the garden, behind the house, so contrived that the visitor may neither be seen from the windows of the cottage nor the public road, with a going and returning, or an incidental approach, instead of the direct cul de sac paths which commonly lead to such places.

7307. A pigsty attached to the north-east or south-west front.

7308. A dung-hill, or a small spot adjoining the pigsty, surrounded by a dwarf wall.

7309. A niche in the wall of the south-east front of the house, to hold two or more beehives, with two iron bars, joined and hinged at one end, and with a staple at the other to lock them up to prevent stealing.

7310. The surrounding fence may be a wall, close pales, a holly, thorn, sloe-thorn, or damson-plum hedge, according to circumstances; if a hedge of any kind, then standard plum, pear, apple, or cherry trees, may be planted in it, and trained against it. Next to the fence, a border should be carried round the whole; a similar border may be formed round the house; and the area for culture will then be thrown into two compartments, one behind the house, and one in front of it. The compartments may be surrounded with a line of gooseberries and currants, and a few standard apples or plums (as being the two most useful fruits for the whole. Against the house may be planted currants, pears, or a vine, according to the situation and climate. Honeysuckles and monthly roses may be planted next the porch; ivy against the water-closet; and the scented clematis against the pigsty. The border round the house should be devoted to savory pot-herbs, as parsley, thyme, mint, chives, &c. and to flowers and low shrubs. The wall behind the hedge, should be devoted to early and late culinary crops, as early potatoes, pease, turnips, kidney-beans, &c. No forest trees, especially the ash
and elm, should be planted in, or if possible, even near the cottager's garden; as these are ruinous to crops; the first both by its shade and roots, and the latter by its roots, which spread rapidly to a great extent, close under the surface. The oak is the tree least injurious to gardens.

7311. Variation may be made in this extent of accommodation, by adopting a different form for the ground-plan of the plot; by different inclinations of surfaces, kinds of fence, sort of materials used for the roof and walls of the house, coloring of the walls, and above all, by adopting different styles of architecture. But whatever is done in this respect, no attempt at ornament or picturesque effect should be made which is at variance with comfort;—latticed windows are cold and uncomfortable; chimney-flues tortured in their direction, with a view to fixing the stack of chimney-tops in some particular point, occasion smoky apartments. A variety of other deviations from common practice made to gratify the eye of the beholder, without any reference to the inhabitant, might be mentioned; but we shall only add, that whatever is most comfortable and durable will please the best in the long run.

Sect. II. Public Gardens.

7312. Public gardens are either designed for recreation, instruction, or commercial purposes. The first include equestrian and pedestrian promenades; the second, botanical and experimental gardens; and the third, public nurseries, market-gardens, florists' gardens, orchards, seed-gardens, and herb-gardens.

Subsect. 1. Public Gardens for Recreation.

7313. Public parks, or equestrian promenades, are valuable appendages to large cities. Extent and a free air are the principal requisites, and the roads should be arranged so as to produce few intersections; but at the same time so as carriages may make either the tour of the whole scene, or adopt a shorter tour at pleasure. In the course of long roads, there ought to be occasional bays or side expansions to admit of carriages separating from the course, halting or turning. Where such promenades are very extensive, they are furnished with places of accommodation and refreshment, both for men and horses; this is a valued part of their arrangement for occasional visitors from a distance, or in hired vehicles. Our continental neighbors have hitherto greatly excelled us in this department of gardening; almost every town of consequence having its promenades for the citizens à cheval and also au pied. Till lately, Hyde Park, at London, and a spot called the Meadows, near Edinburgh, were the only equestrian gardens in Britain; and neither were well arranged. But in 1810, the Regent's Park was commenced from a suggestion of W. Fordyce, Esq., the late surveyor of woods and forests, and it promises to be a scene worthy of the metropolis. It is only to be regretted, that the space available to the public is so much curtailed by interspersed villas, and surrounding rows of houses and gardens: for though from the number of trees, the wealthy citizen who can view the scenery from his horse or coach may recognize the park character; yet by rendering so great an extent of the surface private property, the wanderings of the pedestrian are limited, and his views of the scenery confined.

7314. The public garden of Carlsruhe (fig. 732.), and the town, founded by the Margrave Charles William in 1715, are formed to correspond with each other. The palace (a) is noticed by Sulzer (Théorie des beaux Arts, &c.) and by Hirschfield (Théorie des Jardins, &c. vol. iv. p. 416.), as one of the finest in Germany, and remarkable for having the wings at an oblique angle to the main building. Behind, exactly in the centre of the circular carriage-promenade (b), is a tower (c), which commands a bird's-eye view of the whole park, pleasure and kitchen gardens (d), and the town and church (e). The whole is on level ground, and joined to a natural forest. In the town many English and other foreign artisans were settled. Among the trees near the palace, are some of the finest old tulip-trees, planes, bignorias, sumachs, acacias, cedars, and other exotic trees in Germany.

7315. Boulevards (Boulevard, Fr., or round work; a bulwark, or great bastion, or ram-
part, generally round). Many of the continental cities have a species of equestrian promenade within their boundaries, which is deserving of imitation. These are broad roads, accompanied by rows of trees, near the margin of the city, originally formed on the ramparts, or surrounding fortifications, and completely encircling it. They are highly interesting promenades, especially to a stranger, to whom they give an idea of the topography and most remarkable points of the scene in the most agreeable manner. The boulevards at Paris, Vienna, and Moscow, are particularly to be admired in these respects.

7316. A promenade might be formed in the margin of London, of a very interesting kind, by continuing the street called the New Road through Hyde Park, entering close to where Kensington Gardens leave off, proceeding thence across the Serpentine River, and coming out exactly opposite Sloane-street: then along this street and part of the King’s Road, to the road leading to Vauxhall Bridge; from this bridge along roads already formed, and as may be seen by the map, well suited to lead to Blackheath; then turn towards London through Greenwich Park, so as to display the best views of the metropolis over Greenwich Hospital; form a viaduct or road, on a cast-iron colonnade, across the river, sufficiently high to admit ships in full sail to pass under: descend this, and join the City Road, which joins the New Road, and completes the circle. This course which, with the exception of the bridge, might be formed at no great expense or de-}

rangement of property, would give a grand view of the metropolis, and by now and then deviating from the direct road and returning to it, Kensington Gardens, Hammer-smith Nursery, the King’s Road Gardens, Chelsea Garden, the garden of Loddigies at Hackney, the Regent’s Park, Highgate, Hampstead, and all the most interesting gardens, scenery, and objects close to London, might be rapidly glanced at in one day.

7317. Mountain promenade. One of the finest equestrian promenades that can be imagined might be formed on the hill of Arthur’s Seat at Edinburgh. From the base at Holyrood Park, let a road ascend winding round the hill, including the appendage of Salisbury Craigs, and the knoll to the east, if desirable, to the summit, at a rise not greater than two inches in six feet. Having arrived at the summit, let it wind down again at a similar slope, intersecting the other road, and arriving also at Holyrood Park. Then let or sell the ground to individuals to build on or plant, each according to his taste. The slope of the road would be found so gradual that a two-wheeled chaise might be driven up or down at a trot, which can be done on the Simplon road, where the slope is 2½ inches in six feet. Taking the height of the hill from the park at 700 feet, this would give less than five miles of ascending promenade, and the same number descending. By the formation of these two roads, hundreds of the finest situations in the world, for summer villas and cottages would be formed, and probably in time let or sold, so as to cover much more than the expense, both of purchasing the hill as it now is, and forming the roads in the very best manner.

7318. Public gardens, or pedestrian promenades. These, with very few exceptions, have been in all ages and countries laid out in the geometric style. The Academus at Athens is an ancient example. The summer garden at Petersburg, a modern one. Even in China, where irregularity in gardening is so much desired in general, Ellis (Journal of the Embassy of 1816) informs us, that “the Fatee gardens at Canton, the resort of the fashionable, consist of straight walks.” And however much our gardening has been praised and copied by private persons on the continent of Europe, yet, with the exception of Count Rumford’s walk at Munich, and the late Earl of Findlater’s at Carlshad, almost all the others are very properly in straight lines. The object of public gardens is less to display beautiful scenery than to afford a free wholesome air, and an ample uninterrupted promenade, cool and shaded in summer, and warm and sheltered in spring and winter. In a limited extent, these must be attempted in one principal walk, which, for that purpose, should as much as possible be laid out in a north and south direction. In more extensive scenes, certain covered walks may be devoted to summer, and certain east and west open walks, to spring and winter. The broad open, and narrow covered avenues of the ancient style, are valuable resources on a large scale; these conjoined and laid out in a south and north direction, give in the centre an open, sheltered, sunshine walk in mid-winter; and a close or covered avenue being lined out along each side of the open central one, will afford shady walks for summer, and occasional places of retreat from casual showers in spring. Oxford and Cambridge afford some fine open and covered avenues, though far inferior to many on the continent.

7319. Public squares, of such magnitude as to admit of being laid out in ample walks, open and shady, are almost peculiar to Britain. The grand object is to get as extended a line of uninterrupted promenade as is possible within the given limits. A walk parallel to the boundary fence, and at a short distance within it, evidently includes the maximum of extent; but if the enclosure is small, the rapid succession of angles and turns becomes extremely disagreeable, and continually breaks in upon the pas
des promeneurs, the conversation of a party, or individual contemplation. The angles, therefore, must be avoided, by rounding them off in a large square; in a small one, by forming the walk into a circle; and in a small parallelogram, by adopting an oval form. In laying out a large square (fig. 733.), four objects ought to be kept in view.

1. Sufficient open space (a), both of lawn and walk, so as the parents, looking from the windows of the houses which surround the square, may not at a long time lose sight of their children; 2. An open walk, exposed to the sun, for winter and spring (b): 3. A walk shaded by trees, but airy for summer (c): 4. Resting-places (d); and a central covered seat and retreat (e), which, being nearly equidistant from every point may be readily gained in case of a sudden shower, &c. The statues of eminent public men are obvious and appropriate decorations for squares.

7320. Russell Square, laid out from a design of Repton in 1810, is one of the most complete in this respects in London. It has been objected to as over-plantèd; but this is only a piece of vulgar injustice, applied indiscriminately to every rural artist, all of whom, as a matter of course, conclude, that when magnitude effects the purposes of number, the superfluous plants will be rooted out.

7321. Of the figurative and the more Spenserian, as laid out as a botanic garden, by which means the surrounding inhabitants have an easy opportunity of blending recreation with instruction. This plot being a parallelogram or long square, and the ground being low, Repton proposed to form it into a winding valley, containing a piece of water; the walks to be winding, the trees grouped, and the whole contrived so as to produce an appearance of nature sublime and grand; but his essay was not carried out. The late poet laureate, Pye (Essays), purposed to lay out a square, in imitation of a wild overgrown quarry or gravel-pit, and plant it with thorns, hollies, furze, brambles, ferns, &c. This mode he would adopt on account of its open air.

7322. Edward's Square, Kensington, was laid out, in 1819, in groups and winding walks, in a manner different from most other squares, by Aiglio, an eminent landscape-painter. A small city square might be laid out in terraces, like the Isola Bella, or the gardens of Babylon, and the space beneath usefully disposed of as vaults for goods, or a cattle-market.

Subject 2. Public Gardens of Instruction.

7323. Botanic gardens. The primary object of botanic gardens is to exhibit a collection of plants for the improvement of botanical science; a secondary object to exhibit living specimens of such plants as are useful in medicine, agriculture, and other arts; and a third is, or ought to be, the acclimating of foreign plants, and their dissemination over the country. In choosing a situation for a botanic garden, the leading object must be proximity to the town, city, or university to which it is to belong; and the next, if attainable, a variety of soil, to aid the necessary formation of composts and aspects for different plants. In general, however, there is little choice in these respects, it being sufficiently difficult to procure an adequate extent of surface of any kind near large towns. As the leading object or feature in the view of a botanic garden is the range of hot-houses; and as these must always face the south, it is generally desirable that ground on the north side of the principal public street or road by which it is to be approached, should be preferred to ground on the south side. In the latter case, the hot-houses must be approached from behind, and then the spectator must turn round to look at them, by which their grand effect is lost. The Liverpool and Oxford gardens are in this respect unfortunate; that of Edinburgh fortunate.

7324. The extent requisite for a botanic garden depends upon that of the collection intended to be formed; as well as on the magnitude to which the tree-plants are intended to be grown. A good deal will depend also on whether tender exotics are to be principal or secondary objects of collection, and also on the manner of growing the hardy herbaceous plants. An immense collection of herbaceous plants may be included in a small space, if the soil is loamy, rather inclined to moisture, and if the plants are separated from each other in the rows by bricks or thin tiles, which at once completely divides them and stints their growth, so as to admit a great number being planted on the same space. The extent of the Chelsea garden is little more than three acres; that of the Liverpool garden is five acres; and in both are extensive collections of Mesuri. Lodges have above a thousand species of herbaceous plants, which they keep constantly in small pots, set on beds of scoria. These occupy very little space, and the plants thrive well. Of course the larger-growing kinds are excluded.

7325. The form of a botanical garden is a matter of very little consequence: where the extent is small, a square or parallelogram may undoubtedly be made to contain most plants; but where it exceeds four or five acres, any form will answer; and, indeed, if there is a sufficient quantity of ground, the more irregular the more useful. In the most irregular botanical gardens, both as to form and surface, with which we are acquainted, are those of Königsberg, and Warsaw. A small rill runs through the former, with the most irregular wavy banks on each side; and the latter is on the steep, broken, and almost inaccessible banks of the Vistula.

7326. In laying out the area of a botanic garden, the objects already mentioned, and various others, must be kept in view. If it be merely desired to have a general collection, then a surrounding border for the trees and shrubs; internal compartments for the
beds of herbaceous plants; and a space at one end or side for the hot-houses, frames, compost-yard, &c. will be sufficient; surrounding the whole with a walk, which may also cross the garden in one or more places. Such a walk to display in succession every remarkable feature, is essential to all gardens, whatever may be their extent or kind.

7327. In a complete botanic garden, the following seem to be requisites:

1. A curator's house, with seed-room, office for business, library of reference, herbarium, room for lectures or demonstrations. This is most generally situated at or near the entrance of the garden. Some consider it preferable to place a lodging-house for the gardener, and to place the curator's house with its accomplishments as above, in connection with the greenhouse houses; and this the more especially as botanic gardens are rarely family men, at least in Britain.

2. A group of hot-houses, either in one line, or in a semi-circle, circle, square, half-square, &c. according to taste and other circumstances; or a line of greenhouses, which has all the usual purposes of such, including rooms for the journeymen, where there is no lodge; and lodgings for one man, even if there is a lodge, in order to the farther face.

3. An adjoining arrangement of pits and frames, but not in front of the range of hot-houses, as in a nursery.

4. A compost-ground for all the usual purposes.

5. An aquairst, including a bog pond, spring, and salt-water easters, for marine algae.

6. A rock-work and underneath pendent walls, tunnels, vaults, and caves, open in different degrees and directions for the growth of mosses, ferns, fungi, &c.

7328. Various other sub-arrangements or compartments of this nature may be contrived, as for creeping plants, climbing natives of particular countries, succulents, bulbs, &c.; and the association of plants in this way by strong natural and artificial (alluding to their use) affinities, is well calculated to facilitate both their culture and study. The most complete arrangements of this kind are to be found in the Paris, Dublin Society's, and Glasgow gardens. The size and shape of these sub-arrangements will, of course, be various, which will add greatly to the interest of the walks. They will, in general, be most advantageously placed round the outskirts of the garden, within the marginal plantation, and should be separated by different sorts of rustic walls, or mounds of rock-work, hedges, thickets of evergreens, and other means. They should all be connected by a walk in such a way as that a general spectator may see each scene without being obliged to enter minutely into it; and that whilst none can escape the botanist, he may have an easy opportunity of entering minutely into each or any of them.

7329. The central, or principal part of the ground, should be devoted to one general arrangement of all the phanerogamous plants, including hardy exotic trees and natives. The trees may be kept dwarfed, by being propagated from cuttings, or layers, and by planting in pots, and pruning; and the stave, and other exotics, will of course only be plunged in their appropriate places for a few weeks in the warmest part of each summer, as in the Paris garden. Every plant ought to have its name painted on strong cast-iron tallies, on a bevelled face, in letters so large as to be legible without stooping. If to the name, systematic and English, could be added the Linnaean and Jussieuan class, native country, and time of flowering, it would obviously greatly facilitate the peripatetic study of plants. The tallies once placed there, should never be removed, excepting when the arrangement is to be enlarged, because the name will show that the plant exists, or ought to exist, somewhere in the garden; and will or ought to be placed there in the proper season. Such a collection should, in short, be a transcript of the catalogue of the garden; some of the filices, and most of the fungi, algae, and musci excepted.

7330. Whether the arrangement in the compartments or main area of such a general collection ought to be Jussieuan or Linnaean, must depend on the opinion of those concerned. In the present state of botanical science, that of Linnaeus is the best for the study of nomenclature and technology; it is that generally adopted in Britain and the north of Europe; whilst that of Jussieu is almost universally adopted in France and Italy.

7331. The botanical arrangement in the hot-houses, and as far as that kind of arrangement is applicable, in the different subsidiary or habitat arrangements, should, in our opinion, decidedly be Jussieuan, as presenting the strongest natural affinities, and calculated to promote variety in general appearance, facility in recollecting names, and often answering as to kind of culture. The Paris garden is the most complete in Europe as to comprehensive arrangement, though the collection of plants is inferior to that at Kew or Liverpool. It is remarkable also for its menagerie, containing a collection of living animals of many kinds, lodged in appropriate buildings with surrounding enclosures of different degrees of extent. It also contains specimens of all the different soils, composts, and operations of horticulture and agriculture. A plan of this garden, which contains about seventy acres, and was arranged in its present form by the chevalier Molinos, has been given by Professor Thouin, in the Annales du Musée; and another published more recently by the professor's brother, G. Thouin (Artiste Jardinier), in Plans Raisonnés des Jardins, &c. This plan (fig. 734.) not only contains the ichnography of the garden (1 to 21), but in the margin are placed elevations (22 to 42) of the houses in which the living animals are kept, of the immense buildings in which the
museum of natural history is contained (24), and of the hot-houses (23), and entrance-gates (32).

7332. The entrance to the garden is through a handsome iron railing between lodges (1, and the elevation 32), opposite the bridge of Austerlitz (40). On the left is the menagerie, commencing with the ferocious animals, in a long building, with wings and a fore court; and next in order is a number of small irregular-shaped enclosures of pasture, covered by trees, each devoted to one genus of animals, and containing a building in the centre for their repose or shelter (2 and 3). Passing these we arrive at the dwelling-houses of the professors of natural history; and the large amphitheatre (4, and elevation 35) in which the lectures are given. Here is also the hot-house department (7, and elevation 33), with a sunk area in front for pots and frames; a space called the seed-garden for raising seeds, and for nursing them till they flower. Adjoining is an artificial mount, crowned with a kiosque (5), which overlooks, not only the whole garden, but great part of Paris; it contains a sundial, which, by means of a lens, is contrived to discharge a cannon every day at noon. The museum of natural history is a large building at the upper end of the garden, exactly opposite the entrance (6, and elevation 24); it is separated by a handsome low wall and iron rails from the open garden, which consists of 36 plots, enclosed by lattice-work from the walks, which are all times open to the public. These plots contain specimens of the mode of propagating all herbaceous vegetables, all trees and shrubs (8)—a department which is particularly rich in specimens of grafting and inarching (9); a large basin for aquatics, and aquatic birds and reptiles, situated at the bottom of an excavation, more than ten
feet below the level of the general surface of the garden (10); the sides of this excavation are planted with marsh trees and shrubs. The next divisions consist of florists' flowers arranged according to their colors, heights, and positions (12); of the different productions of agriculture on plants, as the different kinds of hedges, live fences, rows, &c. (13); all the sorts of fruit-trees, vines, and fruit-shrubs, which grow in the open air in France, with different modes of pruning and training them (14); all the sorts of vegetables used in rural economy throughout Europe, the more tender sorts, as the convolvulus battatas, being protected early in the season by glass (15). The general arrangement of all the plants grown in France, tender and hardy, occupies ten plots (16); the classification adopted is that of Jussieu. The tender species are brought from the hot-houses in June, and plunged in their plains. Those of a tender kind and shrubs, which are also pruned by pruning, and brought into flower by ringine. The different sorts of annual plants, and the mode of raising seeds of every kind, is displayed in a large plot (18). There is a general arboretum (17); one of winter or evergreen trees (19); of trees in perfection in autumn (20); of summer trees (21); and of spring trees. The conservatory (22) was for foreign plants only; the botanical gardens (23); museum (24); lodge for East India deer (25); lecture-theatre (26); near which is situated the office of administration for the garden; retreat for buffaloes (27); stable for the equus tribe, with pigeon-house over it (28); flower-shed (29); for goats (30); for camels (31), for elephants (32); for foreign oxen (37), for red deer (39), for the dromedary (40), for packing plants (41), and for a public coffee and milk-house, situated at the base of the mount (38). There is a restaurateur in the spring arboretum (23), also a number of other buildings of less note; and so complete is this establishment, that in some of the rooms destined to show certain branches of culture, there are lodges containing specimens of all the implements in use in that branch. (Annales du Musée; Reyer's Descriptive History of the Paris Garden.)

3734. In the office of administration, which is remarkably complete, is the botanical cabinet (fig. 735.), thus described in the Horticultural Tour: "In the staircase (a) is preserved a tall palm-stem from South America, which had been naturally clasped in a very extraordinary way by some line or twining shrub, and evidently by the root of its invader. Professor Dohrn's room (b) adjoins, and next, the working-room for the professor's assistants (c). Here a respectable-looking female was now employed in fixing dried specimens of plants to sheets of white paper, after they had been arranged for that purpose by Professor Dohrn. As one of the objects of the museum is the display of the specimens of dried plants. They are contained in close presses, and so accurately and conveniently arranged, that the specimens composing any particular genus can be produced for examination the moment they are called for. Another (d) contains specimens of wood, which has been dug up in almost all the provinces of the empire; it is arranged by Sepp of Amsterdam, and edited by Dr. Houttayan, and of many unknown to these laborious Dutchmen. The samples are in general smoothed with the plane, the better to display the grain, and the extreme beauty of some kinds. A vase, nicely formed out of the stem of a date-palm, is a curious object: it is about a foot and a half in diameter, and somewhat more in height. A large apartment (f), extending the whole breadth of the building, contains the seeds and seed-vessels of plants, with specimens of vegetable products in general. In the same room several commodious presses and drawers are appropriated to the reception of the seeds saved in the gardens from the most rare or tender plants, particularly those of only annual duration. We may add, that the great attention paid to this part of the business of the garden, the saving of seeds, and keeping them in the nicest order, received our unqualified approbation. A glazed frame containing numerous skeletons of leaves and flowers, had a very pleasant effect. It was the palm of Ceylon (Coraypa umbraculifera) decorate the ceilings of two of the rooms." (Hort. Tour, 333.)

SUBSECT. 3. Commercial Gardens.

7335. Public nursery-gardens come first in order. In choosing a situation in which to establish a nursery, two points are to be considered, fitness as to the disposal of the produce, and fitness as to shelter, aspect, and soil. Where it is intended to attempt a general nursery business, regard must be had to the leading roads of the district, the means of carriage by land or water, the kind of objects that will be most in demand, whether seedlings, fruit-trees, or tender exotics, or all of these. Where a local business is to be commenced, it is evident much will depend on the choice of a conspicuous situation in some line of road of general resort, and as near as possible to some town or city. As far as respects shelter, aspect, and soil, the remarks already submitted in reference to private nurseries may suffice. The best general soil is evidently a free tender loam; and the best general aspect or exposure, one inclining to the north; as precocity is no advantage in a nursery, but the contrary, and all seedlings and tender plants will be the safer till they come up, and come up more vigorously, when brought on not so much by the direct rays of the sun as by his indirect influence on the atmosphere. Another great advantage of a northern exposure is, that plants and trees may be taken up, as well as planted, later in the season, than in one of a contrary nature. Grafting also, and making good deficiencies and other nursery-operations, which are generally deferred to the last moment, may be done with less injury to the trees and plants.

7376. The extent of a nursery must depend on the means of the occupier, and the probable extent of market. It will also depend, in some degree, on the kind of articles to be chiefly cultivated, and the mode of cultivation to be pursued. Where manure is scarce, such a system of alternate nursery and market-garden crops must be adopted as shall preserve the ground in heart; but where manure is more abundant the severe crops may succeed one another more closely. Where thorns and seedling forest-trees are to be the chief articles grown, it is evident less ground will be required than when transplanted forest-trees are to be the chief article produced.

7377. In laying out a nursery, the objects to be cultivated, and the kind of business to be expected, must be leading guides in the design, and the duration of the tenure will naturally have a material influence on the execution. The following seem objects desirable for a complete nursery: 
PRACTICE then and but, and. A seed-shop and counting-house or office, which should be connected with the house for the master’s convenience; but, at the same time, have each distinct entrances. The counting-house should have a large room, or a bell placed over, or in some conspicuous situation for regulating the hours of labor; also a speaking-pipe to the packing-court and centre of the hot-houses.

A journeyman’s living-room, and a number of sleeping-rooms for the whole or a part of the jour- neymen employed by the year, or otherwise, communicating with the packing-court, or in some cases, on a small scale, occupying part of the ground-floor of the house. From this appendage should be a speaking-pipe and bell to communicate with the counting-house and the master’s sleeping-room.

A tool-house, efficiently furnished and arranged, and with the seed-shop. The tools should be at least weekly examined by the foreman before paying the men. The larger number-sticks or tallies, not in use, should also be kept here.

A museum and herbarium-room, in which models (in plaster, Roman cement, or paper mâché) of all the fruits, and different species of plants, should be hung in the nursery, so as to be kept, in order to show to purchasers, in seasons when the plants to be purchased are not in fruit or in flower.

Packing-sheds, surrounding a part or three sides of a packing-court, one of these being open to, or commanded by, the window of the office and common living-room of the house. Over these should be a range of seed and store loft.

A stable, cart-shed, cow-house, and pigsty, if such conveniences are desired, communicating on one side with the packing-court, and on the other with the wall: a coal-shed, a horse-dung-heap, and other similar objects in the back area of the dwelling-house.

A store-room, or laying-in-ground, three or more times the size of the packing-court, in which to inhum the roots of plants taken up, to be ready for sale or packing.

A plot for the hot-houses, square, octagonal, or polygonal in the circumference or boundary, and the frames and beds, and the green-house, having the space sufficient for the green-house plants during summer. If the whole boundary cannot be at once, or perhaps not at all, covered with glass, the naked part may be a wall for training fruit-trees, and the north border for auricula frames. The most convenient cutting is four in a plot. Should the in the middle of a square may be very properly covered with glass, facing the centre; that of northern aspect being well adapted for striking plants, and preserving, or retarding such as are in flower. The exterior of this boundary line should be arranged for pots, potting, tau-furnace, and general working sheds; or, if this be not wanted on the north, the same portion of the wall may be devoted to the training of fruit-trees.

A compost-ground for different sorts of earths, gravel, manure, and the rubbish-heap.

A rotting-ground for depositing tree-seeds, in layers of sand or ashes, in order to rot off their external coats, and promote the decay of nuts or other hard covers of seeds. (679.)

A parterre for the culture and display of such of the border and florists’ flowers as are grown in the nursery, and for a specimen of rock-work, a flower-stage, aquarium, apiary, and covered seat for visitors.

The main area of the nursery should be laid out, as nearly as the circumstances will admit, in parallelograms, of any convenient dimensions, but not wider than the ordinary length of a garden-line, say under 150 feet, which allows of a row sufficiently long for any purpose. The chief reason for the parallelogram form is, that all rectangular figures are most easily cultivated and measured, and the reason for their being all of the same size is, in order that the master may readily, after a little experience, form a tolerably accurate idea of the quantity of every kind of nursery labor requisite for a plot of this shape and size. Thus, supposing each division to contain half an acre; then one man will dig it in one day, trench it in two days, hoe it, if in wide rows, in a fourth of a day, if in narrow rows, in half a day. A woman, if in beds, will weed it, if very thick of weeds, in two days; if thin of weeds, in one day, and so on. The compartments should, as much as possible, be cropped with one general class or kind, and by rotation. As, for example, for seven years: 1st, Break up from grass with turnips after trenching; 2d, Transplanted forest trees, two years; 3d, Green crop, one year; 4th, Annual flowers, for seed, one year; 5th, Seedlings, one year; 6th, Transplanted fruit-trees, four years; 7th, Bedded thorns, two years; and so on. Some compartments must be set apart for common stooks; and if the circumferential borders are not sufficient or proper for stooks of rare or peculiar sorts, others must be contrived by means of hedges, pales, or walls, to produce shelter and shade for cuttings, fit situations for bog-earth borders, American stooks, bog plants in general, and similar purposes. If the borders are all of the same width, say ten or twelve feet, it will simplify all future calculations as in the compartments.

A grand central, and a circumferential walk, with some cross walks, should be contrived to display the whole nursery to the best advantage. A narrow or common sized border should accompany these walks, excepting where the broad circumferential border comes in; and in the narrow borders should be displayed single specimens of all the more rare trees and shrubs grown either from seed, or by other means, for sale, and of all the perennial, biennial, and annual border-flowers sold to the public in the form of plants, roots, or seeds. Those may be excepted which are grown in the flower-garden, rock-work, and aquarium.

A nursery-orchard should be formed of some compartments near the house; and in these, one or better two plants of each of all the hardy standard fruit-trees should be planted, in order to come into bearing, and admit of proving the kinds; and from which alone the grafts and buds should be taken, (unless on the introduction of new and valuable sorts, in which case such grafts as can be got must be taken till some of the progeny moved to the nursery-orchard come into a bearing state,) which are to be used in the nursery. This
orchard should be surrounded by a wall, on which to grow specimens of such sorts of plums, cherries, and pears, as do not ripen well as standards; thehardier sorts of grapes, and peaches, nectarines, and apricots. The tenderer sorts of vines, and some few peaches, which are tender in the northern counties, may be grown, one of a sort, under each rafter in the range of hot-houses.

7353. The compartments for stools of every description, and the borders for cuttings, should be as near the house as possible, as on these, men are employed a greater number of days in the year than on any other of the compartments, and therefore it is desirable such compartments should be more immediately under the eye of the master.

7354. Fruit-tree and seed-bed compartments should come next; then transplanted shrubs; next young forest trees transplanted; and, in the most distant parts, the larger forest trees, as requiring least culture of all. But a proper attention to rotation will not admit of this arrangement being completely attended to; and to keep the ground in good heart is as essential to success as keeping the men at work.

7355. In some of the principal nurseries which have risen to their present degree of eminence by degrees; and where consequently one building or additional object has been added to another, without having any general plan in view, the greatest confusion in appearance, and a considerable loss of labor, is the final result. The best way in such a case is to pull down great part of the hot-houses and outbuildings, and re-arrange the whole on some plan which will admit of a regular tour of inspection, either by the master or stranger-visitants. A fine example of this has recently been given by Messrs. Lodgives; whose arrangement, and mode of displaying the whole to strangers, is so perfect, that the time saved in conducting visitors through the premises will be no small gain.

7356. The Hackney nursery (fig. 736), or commercial botanic garden, affords an example of a small irregular layout, laid out both with due consideration as to effect botanical science, and economy as to culture. The entrance (a) leads to the range of hot-houses, and commences with the stoves (b), proceeds to the grand palm-house (c), thence to the dry-stove bulbs, and other articles (d), to the double camellia-house (e), and the green-house plants (f). The area enclosed by these buildings is devoted to the culture of plants in pots, raised from seeds of rare American and herbaceous plants, and to collections in pots ready for sale. The outside space on the north side (g) is used as a depository for soils, pots, and other agents of culture; and for propagating-pits (h), and nursery-plantations of delicate articles. The visitant having arrived at the end of the artificial climate (i), next enters on the course of the arborium (j, k), which is arranged alphabetically, and occupies one side of a winding walk, till it has exhausted all the trees and shrubs, which will grow in the open air, with the exception of some of the more common species, of the roses, and American select shrubs. This walk crosses a public lane (k), on an elevated bridge, and entering an irregular piece of ground, winds round it till it terminates in an American ground in the centre (m), composed of a series of revolutions of grass-walks, with intervening beds of bog-earth, displaying a complete collection. The arborium alphabet is only carried along the right hand of the arborium walk (l, l), and on the left hand is a complete collection of roses for a certain length, and then herbaceous plants for the rest of the space. The beauty of this arrangement is, that there is no interruption to the series when once entered on, while at the same time any of the genera along the winding paths may be gone to at once by small paths, which occur here and there across the borders. A visitant wishing to see the American collection only, will proceed at once to its commencement (l), and wind along it till he arrives at its termination (m), and so on. The arborium contains a number of species and varieties not before introduced, or hitherto neglected in this country. Every species commences with a named specimen, left to attain its natural size and shape next the walk; behind, in a line, are stools for laying or stocks for grafting, and the next are three lines are devoted to the reception of the young plants till sold or disposed of. This mode saves much trouble in culture, and at once shows the purchaser the sort of tree he is to get; and assures him that he is getting its real progeny. The names of the trees, American shrubs, and the numbers of the herbaceous plants and roses, are painted on the ends of bricks, which are let half their length into the ground, in an oblique manner, so as their ends may meet the eye at a favorable angle.

7357. Of florists' gardens there are two sorts; the first for the purpose of forcing flowers in pots, for drawing-room gardens, and raising others in the open air for the flower-market; the second for the propagation and culture of florists' flowers, in order to vend their bulbs and plants.

Both should be situated near a large town, as a market for the produce of the first kind; and to ensure visitors to the flower-shows of the second. A low situation, if possible near the sea, but at all events with a humid atmosphere, is to be preferred for the culture of bulbs; and no florists'
flower will thrive in an atmosphere impregnated with coal-smoke. Very little skill is requisite for laying out either of these gardens to those who understand the culture they require. The hot-house, pit, and frame departments should be kept together; close to them the compost, dung, and tan grounds or sheds; next the ground where pots of roses, &c. are plunged; and the least near parts remain to be devoted to the culture of flowers or flowering shrubs in the open ground. For the conveniency both of culture, without treading on the plants, and of gathering the flowers, the whole is generally laid out in beds, sometimes with box-edgings, but more commonly without any, which for bulbs and plants to be annually removed, admits of more effectual culture.

7358. Market-gardens are of two kinds; those cultivated by manual labor, and those wholly or in part by the plough. In choosing a fit situation for a market-garden, regard must not only be had to the requisites for a good kitchen-garden, as to shelter, soil, water, &c. (2382. to 2430.), but to the probable market-kind of produce to be grown, &c. The smallest extent must depend jointly on these circumstances and the capital to be employed. The smallest extent of surface and capital is that in which a man performs the whole of the labor himself, and this so entirely depends on the articles cultivated, the nature of the soil, and mode of culture, that it may vary from one to two acres, and where grain and seed crops are introduced, to a greater number. As to the quantity of ground which a man of capital may manage by this way, no limits can well be assigned to an active and vigilant master. Some London gardens of this description, entirely cultivated by manual labor, exceed 100 acres. In laying out a market-garden there cannot be said to be anything peculiar: the general points of order, distinctness of compartments, and keeping the plots as much as possible in squares and parallelograms, are of obvious importance.

7359. Public orchards are of various kinds; garden-orchards, where the ground is cultivated and cropped with culinary vegetables or small fruits; arable orchards, where the trees are in rows, and the spaces between in aration; and pasture-orchards, where the trees are scattered over pasture-lands. In fixing on a situation for either kind, the three chief points are soil, sub-soil, and shelter, which have been already considered in treating on private orchards, as well as the planting and kinds of fruit-trees.

7360. Physic or herb-gardens, if for growing aquatic herbs, as mint, should be situated in a low moist soil; if for aromatic herbs, as lavender, rosemary, &c. on a dry poor soil; and if for roses and similar plants, for producing flower-leaves, for the distiller, the soil should be loamy and rich. In laying out this kind of garden, the only point in which skill is requisite, is the contrivance of a system of irrigation for the mints.

7361. Seed-gardens, or seed-farms, require a dry soil; and two should never be situated together, if destined for the same sorts of seeds. All the art in them consists in cropping, so as to ensure seeds true to their kind. Indeed, the culture is by far the most important consideration, not only in this, but in the four preceding descriptions of public gardens; and this is still more the case with respect to gardens for peculiar crops, as for the bulbs of white lily, rhubarb-roots, licorice, &c. which, as to laying out, require no further notice.

---

Chap. V.

Of the Practitioners of Landscape-Gardening.

7362. The practice of landscape-gardening has been thought such a simple business, that every proprietor might perform it for himself. The same thing, indeed, may be said of the practice of medicine, law, or cookery, for every one can prescribe a cure, decide a quarrel, or boil an egg. "Had the art of laying out grounds," Repton observes, "still continued under the direction of working-gardeners or nurserymen, the proprietor might suprisedede the necessity of such landscape-gardeners, provided he had previously made this art his study; but not (as it is frequently asserted,) because the gentleman who constantly resides at his place must be a better judge of the means of improving it, than the professor, whose visits are only occasional; for if this reason for a preference were granted, we might with equal truth assert, that the constant companion of a sick man has an advantage over his physician. Improvements may be suggested by any one; but the professor only acquires a knowledge of effects before they are produced, and a facility in producing them by various methods, expedients, and resources, the result of study, observation, and experience. He knows what can and what cannot be accomplished within certain limits. He ought to know what to adopt, and what to reject; he must endeavor to accommodate his plans to the wishes of the person who consults him, although in some cases they may not strictly accord with his own taste." (Observ. on Landsc.
A more wise plan than that of doubting on the subject would be to have the separate opinions of different landscape-gardeners and architects; for no opinion need be followed if disapproved of; while the probability is, that there would be something valuable in each, and the proprietor might finally, aided by the artist he preferred, decide for himself, never, however, forgetting the idea of a consistent and beautiful whole. As to the expense of opinions, Girardin observes on this subject, “N’allez pas le regarder — il vous en coûtera bien davantage pour des variations, et des retouches continues.”

The intimate connection between landscape-gardening and architecture; the propriety and advantage of the joint consultations of the landscape-gardener and the architect, as to the situation, aspect, and style of the house; together with the almost unavoidable encroachments of the former on the latter, by designing and executing garden-buildings, has given rise to an opinion, that the landscape-gardener ought to combine the functions of the architect. Repton justifies the idea, by referring to the many excellent houses built by Brown, with no other knowledge than that acquired by observation of all the best houses; and of Kent, who was at once landscape-gardener, architect, and historical painter. We are of opinion, that in the case of garden-buildings and small villas, or ornamented cottages, the knowledge both of the theory and practice of architecture, which it is necessary every landscape-gardener should possess, may sometimes enable him to combine the duties of both professions; but such are the advantages of a division of labor in the fine, as well as in the useful arts, that in all more extensive buildings, and indeed even in those we have mentioned, we would recommend the employment of a regular architect, jointly with a landscape-gardener, as a surgeon consults with a physician in important cases. — The duties of the landscape-gardener resolve themselves into the formation of a plan or design, and the carrying of it into execution.

Of the Study of the given Situation and Circumstances, and the Formation of a Plan of Improvement.

Whatever may be the situation and circumstances where the opinion of a landscape-gardener is desired, he should be furnished with a written or verbal instruction as to the points to which he should chiefly direct his attention; with a complete map of the estate, and an accurate detailed history and description of its localities and peculiarities. From these, from topographical and county surveys, and a residence of a few days or weeks, according to the extent of the subject and season of the year, (spring, before the leaves expand, being the most favorable time,) he will be able to procure every requisite information, and to establish in his memory every thing relating to the situation and vicinity. He is then, and not before, to embody and mature his ideas of improvement; directing his attention first to the situation and aspect of the house and offices, the extent of the park, and the emplacement of the kitchen-garden; next to the general masses of wood; and then, successively, to the breadth of lawn, the situation and character of water, the pleasure-ground, farm, and other details. Before making up his mind on any part of the subject, he will often find it of importance to have sections taken of the grounds in different directions, levels of springs, and rills, &c.; and most frequently he will have occasion for stakes, for marking out lines on the ground; of flagstaffs or poles, from six to fifty feet high, to represent the effect of trees (fig. 737.) and other objects; of strips of white sheeting, to show the effect of water, by forming a white outline on a perfect level; of frames partially covered with boards, to show the effect of buildings; and he may even require boring-irons, or pits dug, in order to enquire into the nature of the subsoil. Being furnished with a plan of the present state of the grounds, (such as fig. 351.) he will, as he makes up his mind on particular improvements, mark them down on this map in pencil, and when the whole is finally adjusted, he will put them in red, or in any distinguishing color. And on one or more general or panoramic views (fig. 355.), as well as on the particular views which he may have taken on different spots, he will also mark
in red the outlines that will be made by the improvements adapted to the different situations. In addition to these, he will show the effect, by geometrical sections taken in different directions across the grounds, to show the ground's surface. His next operation is to make a vertical profile (figs. 533, 354.), showing the effect of the whole, supposing the alterations to be fifteen or twenty years completed, with corresponding, panoramic, or general views (fig. 355.), and with particular landscapes.

7365. It remains for him to give reasons in writing for all that he proposes; a practice which no employer or artist should ever omit to have done, as such opinions remain as data, to be referred to concerning the management and future effects; as well as in point of present or future justification of the taste, both of the artist and proprietor. This may be done in the following order: 1. Recapitulating the given instructions; 2. The characteristic features, and other details, of the given situation and vicinage; 3. A description of, with the reasons for, the general outline of improvement; 4. The description of, with the reasons for the detail; 5. An outline of the future management; 6. Directions for the execution; and, 7. An estimate of the expense.

7366. In all these discussions proper references will be made to the maps and sketches. Simple language will of course be employed in describing future effects; but, above all, simple sketches, which shall owe little of their effect to shading, and none to coloring, or finishing, are essentially necessary.

7367. Girardin seems to have been the first who suggested this mode of obtaining an opinion systematically; and his remarks on the fallacious effect of beautiful drawings instead of outlines, are well deserving of attention. "Vous savez bien mieux que cette esquisse ne soit qu'un simple trait, et ne présente d'abord que les formes principales des objets, et la disposition générale des grandes masses de votre ensemble. Un dessin bien finie ne manquera pas de vous seduire par l'agrement de la touche d'un habile artiste; vous vous déterminerez d'après un dessin dont vous ne réussissez peut-être pas à obtenir l'effet dans la nature, et il faut bien mieux avoir d'abord une large idée dans l'esprit, pour esquisser ensuite en détail..."

7368. Repton has the merit of first employing this system elegantly and extensively in England, and, of adopting, instead of one entire landscape to show the previous taste, and another to show the effect of the alterations, a slip paper of the size and shape of those parts of the landscape which require alterations. This is fixed at one edge of the entire landscape, and lies flat over part of it, so that when lifted up it shows the full effect. It must be confessed, however, that, though an elegant mode, it is not perfectly fair, since the view in which the cut paper forms a part can never look so well as the other, even from the mere circumstance of the bounding line of the paper. For some cases, however, it may be used, though in general it will be found, that two entire landscapes afford the most impartial means of judging of the effects of an improvement. The discussion and sketches of the place, and improvements being finished, and bound in a book, the ground or working plan may be copied on canvas, or copied on parchments, of the same size as the plan of the alterations. The other plan will be painted on rollers, to be preserved along with the book of notitia. These being delivered to the proprietor, he will determine, after mature deliberation, whether or not he will adopt the whole, or any part of the improvements, previously consulting those friends whose taste or judgment he considers adequate to forming a judicious opinion on the whole, or any one part of the subject. "Lorsque l'esquisse de votre ensemble sera faite, alors vous réfléchirez, vous concerterez, vous discuterez avec des gens de goût, l'ordonnance générale de la disposition qu'elle vous présente."

In this example of forming a plan, we have had in view a dull and nearly flat site, where nothing has been done; but it is evident that the same general principles are applicable to such places as are to be altered, diminished, or enlarged.

7369. By a general plan, accompanied by others more detailed, of the kitchen-garden, pleasure-grounds, terrace, &c. and by the explanatory details of the book of notitia, any gardener of ordinary intelligence may execute the most intricate design, and if this design has been carefully formed from inspecting the premises, and proper general views have been minutely taken from different points, the landscape-gardener may show the effect of future improvements with confidence, and leave behind him the Notitia, or Book of Improvements, or, in other words, such plans, sections, views, and written instructions, as may enable the gardener gradually to produce them, with nearly as much certainty as an architect directs a builder to raise an elevation of masonry. Distantly situated proprietors, ambitious of displaying some refinement of ideas on rural matters, might in this way first procure, and then work to a general plan; instead, as is often the case at present, of working according to their own crude notions; and producing scenes which afford no pleasure to any one but their owner, and only to him whilst he remains in statu quo as to taste.

Sect. II. Of carrying a Plan into Execution.

7370. Whether a plan be carried into execution by contractors, or by the proprietor at his own risk, must depend on circumstances, both respecting the knowledge, taste, and leisure of the proprietor, and the nature and extent of the improvements. Where an entire new house and grounds are to be created, an eminent substantial contractor for the buildings, and another for the ground operations, will be found the most speedy and certain as to expense; the work, in both cases, being liable to be regularly examined at stated periods by a neutral surveyor, accompanied by the original designers of the improvements. If this mode is not adopted, the whole or greater part may be done under the eye of the owner and his steward; various, and as many parts as possible, being let by the job. We shall take a cursory view of the chief objects of alteration or addition; and indicate some things in each, which in most cases may be more profitably done by the job, premising, that whenever the cost or intricacy of any piece of work is consider-
able, unless a contractor of some respectability is employed, the work is much better done by the laborers of the proprietor.

7371. Buildings. All alterations or new erections may be readily estimated and executed by contract, and, almost in every case, at less expense to the proprietor. The mere difference between the trade price and the gentleman’s price of the materials and labor, and between the hours kept, and quantity of work done in a given time by a journeyman to a master-tradesman and to a gentleman, will (if the former should, by error in estimating, find no other gain), afford a certain profit to the tradesman; and thus, suppose a contractor to estimate a piece of work at 1000l., and which the proprietor, changing his mind, instead of letting to the contractor, executes himself, and finds the amount 1100l., the contractor, had he got the job, would have actually had a profit, and the owner been a gainer of 100l. The mansion, domestic and farming offices, garden-walls, and hot-houses, may all be separately contracted for.

7372. Ground. The removal of ground, fences, or digging, may in every case be let by the job, and with decided advantage to both parties. The extent of particular contracts should, of course, be in proportion to the responsibility of the contracting parties.

7373. Planting. The enclosures and the preparation of the soil may, in all extensive cases, be executed by contract; but the planting or insertion of the plants, on which so much depends, should uniformly be done by day-work; excepting, however, those cases in which a respectable nurseryman will engage to put in a certain number of plants of a certain kind, size, and age, and maintain them there for at least three years. In some extensive cases, the land may be prepared by fallowing, which the adjoining farmers will generally undertake at a very moderate price per acre. In most cases, the contractor for fences, of whatever description, should undertake to uphold them for a given number of years; and in cases of thorn-hedges, or other live fences, until they become sufficient barriers.

7374. Road and walk making may frequently be contracted for; but in this case, as in every other, much will depend on the skill, activity, and experience of the gardener or general overseer. This subject will be found illustrated at greater length, and in a manner incompatible with the nature of this work, in the second edition of our Treatise on Country-Residences, 4to.

---

PART IV.

STATISTICS OF BRITISH GARDENING.

7375. After having considered gardening as to its history, as to the scientific principles on which it is founded, and the application of these principles to the different branches of practice; it remains only to take a statistical survey and estimate of its present state and future progress in the British isles.

---

BOOK I.

OF THE PRESENT STATE OF GARDENING IN THE BRITISH ISLES.

7376. The present state of British gardening, as to knowledge, has been the subject of the former parts of this work; but its importance, in the general economy of society, can only be learned by a statement of the manner in which it is actually carried on; the modifications to which it has given rise in the pursuits of those who have embraced the art as a source of livelihood; of the kinds of gardens employed by men of different orders in the state; of the principal gardens as distributed in the different counties of Britain and Ireland; of the British authors who have written on gardening, and of the private or professional police, and public laws relative to gardeners and gardens.
Of the different Conditions of Men engaged in the Practice or Pursuit of Gardening.

7377. Gardeners may be arranged as operators or serving gardeners; dealers in gardening or garden-tradesmen; councillors, professors, or artists; and patrons.

Sect. I. Of Operators, or Serving Gardeners.

7378. The garden-laborer is the lowest grade in the scale of serving gardeners. He is occasionally employed to perform the common labors of gardening, as trenching, digging, hoeing, weeding, &c. Men for the more heavy, and women for the lighter employments. Garden-laborers are not supposed to have received any professional instruction, farther than what they may have obtained by voluntary or casual observation. In all gardens where three or four professional hands are constantly employed, some laborers are required at extraordinary seasons.

7379. Apprentice. Youth intended for serving, or tradesmen-gardeners, are generally articled or placed under master or tradesmen gardeners, for a given period, on terms of mutual benefit: the master contracting to supply instruction, and generally food and lodging, or a weekly sum as an equivalent; and the parents of the apprentice granting the services of the latter during his apprenticeship as their part of the contract. The term agreed on is generally three years; or more if the youth is under sixteen years of age but whatever may be the period, by the laws as to apprentices it must not extend beyond that at which the youth attains the age of manhood. No one can ever expect to attain to the rank either of master-gardener or tradesman, who has not served an apprenticeship to the one or the other. In general it is preferable to apprentice youths to master-gardeners, as there the labor is less than in tradesmen's gardens, and the opportunities of instruction generally much greater.

7380. Journeyman. The period of apprenticeship being finished, that of journeyman commences, and continues, or ought to continue till the man is at least twenty-five years of age. During this period, he ought not to remain above one year in any one situation; thus, supposing he has completed his apprenticeship in a private garden at the age of twenty-one, and that his ultimate object is to become a head-gardener, he ought first to engage himself a year in a public botanic garden; the next year in a public nursery; that following, he should again enter a private garden, and continue making yearly changes in the most eminent of this class of gardens, till he meets with a situation as head-gardener. The course to be followed by an apprentice intended for a tradesman-gardener is obvious; having finished his period in a private garden, let him pass through a botanic and nursery-garden, and then continue in the most eminent of the class of public or tradesmen's gardens, to which he is destined.

7381. Foreman (before-man, or first man). In extensive gardens where a number of hands are employed, they are commonly grouped or arranged in divisions, and one of the journeymen of longest standing employed as foreman or sub-master to the rest. Whenever three or more journeymen are employed, there is commonly a foreman, who has a certain extent of authority at all times, but especially in the absence of the master. This confers a certain degree of rank for the time being, but none afterwards.

7382. Master-gardener. A journeyman has attained the situation of master-gardener, when he is appointed to the management of a garden, even if he has no laborer, apprentice, or journeyman under him; but he has not attained to the rank of master-gardener till having been a year in such situation. Afterwards should he be obliged to work as journeyman, he still retains the rank and title of master-gardener but not of head-gardener.

7383. A head gardener, or upper gardener, is a master who has apprentices or journeymen employed under him. Out of place and working as a journeyman, he retains the rank and title of master-gardener, but not of head-gardener.

7384. Nursery foreman. This is an important situation, the foreman being entrusted with the numbered and priced catalogues of the articles dealt in; authorised to make sales; entrusted to keep an account of men's time, &c. (see Time-Book, 2938.) and in consequence it entitles the holder to the rank of head-gardener while so engaged, and to that of master-gardener ever afterwards; the same may be said of foreman to public botanic gardens, and royal or national gardens.

7385. A travelling gardener is one sent out as gardener, or collector of plants, along with scientific expeditions; he is generally chosen from a botanic garden; and his business is to collect gardening productions of every kind, and to mark the soil, aspect, climate, &c. to which they have been habituated.

7386. Botanic curator. This is the highest situation to which a serving gardener can attain next to that of being the royal or government gardener. He superintends the culture, and management of a public botanic garden; maintains an extensive correspondence

Part IV.
with other botanic curators; exchanges plants, seeds, and dried specimens, so as to keep up or increase his own collection of living plants, and herbarium sicum. Abroad, for want of sufficiently intelligent practical gardeners, they have what are called directors and inspectors of botanic or other government gardens; but no such office is requisite in this country.

7387. **Royal gardener,** court-gardener, or government-gardener; Jardinier de la Cour, Fr.; Hoffgartner, Ger.; and Giardiniere della Corte, Ital. This is the highest step, the sumnum bonum of garden-ervitude. In foreign countries, the court-gardener wears an appropriate livery, as did formerly the head gardeners of the principal nobility, as well as the court-gardeners of this country. At present this remnant of feudal slavery is laid aside in every grade of British garden-ervitude.

**Sect. II. Tradesmen-Gardeners.**

7388. **Of tradesmen-gardeners,** the first grade is the jobbing gardener, who makes and mends gardens, and keeps them in repair by the month or year. Generally he uses his own tools, in which he is distinguished from the serving gardener; and sometimes he supplies plants from a small sale-garden of his own.

7389. **Contracting gardeners,** or new-ground workmen, are jobbers on a larger scale. They undertake extensive works, as forming plantations, pieces of water, roads, kitchen-gardens, and even hot-houses, and other garden structures and buildings. Formerly, and especially in Brown's time, this branch of trade was combined with that of the artist-gardener, but now since the principle of the division of labor has been so much refined on, they are generally separated.

7390. **Seed-growers** are as frequently farmers as gardeners; their gardens or fields are situated in warm districts, and they contract with seed-merchants to supply certain seeds at certain rates, or to raise or grow seeds furnished to them by the seedsmen on stipulated terms. The great test of excellence here is never to grow at the same time such seeds as may hybridise the progeny by impregnation.

7391. **Seed-merchants, or seedsmen,** deal in garden-seeds and other garden-productions; in general they combine the business of nurserymen or florists, but sometimes confine themselves entirely to dealing in seeds wholesale, or to a sort of agency between the seed-growers and the nursery-seedsmen.

7392. **Herb-gardeners** grow herbs, either the entire herb, as mint, or particular parts, as the bulb of lilium, and the flower of the rose for medical purposes, or for distillation or perfumery.

7393. **Physic-gardeners, herbalists, or simplicists,** not only grow herbs for the purposes of medicine, or perfumery, but collect wild plants for these purposes. Formerly, when it was the fashion among medical men to use indigenous plants as drugs, this was a more common and important branch of trade. They have commonly shops appended to their gardens, or in towns, in which the herbs are preserved, and sold in a dried state.

7394. **Collectors for gardens.** The first variety of this species is the gipsy-gardeners, who collect haws, acorns, and other berries and nuts, and sell them to the seedsmen; the next are those who collect pine and fir cones, alder-catkins, and other tree-seeds, which require some time, and a process to separate the seeds from their covers, and clean them before they can be sold; and the highest variety are those gardeners who establish themselves in foreign countries, and there collect seeds and roots, and prepare dried specimens of rare plants for sale.

7395. **Orchardists of the simplest kind** are such as occupy grass-orchards, where the produce is chiefly apples, pears, and plums, for cider or kitchen-use; the next variety occupy cultivated orchard-grounds where fruit-shrubs, as the gooseberry, currant, strawberry, &c. are grown between the fruit-trees; and the highest variety occupy orchards with walls and hot-houses, and produce the finer stove-fruits and forced articles.

7396. **Market-gardeners** grow culinary vegetables and also fruits; the simplest kind are those who grow only the more common hardy articles for the kitchen, as cabbage, pease, turnips, &c.; a higher variety grow plants for propagation, as cauliflowers, celery, and artichoke-plants, and pot-herbs, as mint, thyme, &c.; and the highest variety possess hot-beds and hot-houses, and produce mushrooms, melons, pines, and other forced articles and exotic fruits. They have often shops at their gardens, or in towns, for the disposal of their produce; and these, when fruit is chiefly dealt in, are called fruit-shops, where culinary vegetables are joined, green-grocery shops. Most commonly, however, the culinary vegetables are carried to market, and there disposed of to such as retail them in shops or on stalls. Occasionally they are deposited for sale in the hands of agents or brokers, and sometimes shops are supplied regularly on certain conditions.

7397. **Florists** are either market-florists who grow and force flowers for the market, and of this subspecies are two varieties, those who grow only hardy flowers to be cut as rose-
gays, and those who deal chiefly in exotics or green-house plants to be sold in pots. The other subspecies is the select florist, who confines himself to the culture of bulbous-rooted and other select or florists' flowers, who has annual flower-shows, and who disposes of the plants, bulbs, tubers, or seeds.

7398. Botanic gardeners are such as devote themselves exclusively to the culture of an extensive collection of species for sale; these may be either limited to indigenous kinds, as was the botanic garden of the late Don of Forfar, embracing all hardy plants, or extending to tender exotics. Botanic gardeners also collect and dry specimens of plants, and also of mosses, fungi, algae, &c. for sale: to this they often join the collecting of insects, birds, and other animals.

7399. Nursery-gardeners, or nurserymen. This is the highest species of tradesman-gardener. Their business is to originate from seed, or by other modes of propagation, every species of vegetable, hardy or exotic, grown in gardens, to rear and train them for sale, and to pack or encase them, so as they may be sent with safety to distant places. The nurseryman is commonly also to a certain extent a seed-grower, and is generally a seed-merchant, supplying his customers annually with what seeds they require for cropping their gardens as well as with the trees they use in stocking them. The simplest variety of nursery-gardener is he who confines himself to the rearing of hedge plants and forest trees; the highest, he who in addition to all the hardy trees and plants maintains at the same time a collection of tender exotics.

Sect. III. Garden Counsellors, Artists, or Professors.

7400. The first species of this genus of gardeners, is the garden surveyor, or valuator. His business is to estimate the value of garden labor and produce, and of garden structures, edifices, and gardens themselves. When a proprietor lets his house and garden to a tenant for a certain number of years, the stock of the garden is valued, and either entirely paid for by the tenant, or it is again valued when the latter quits the premises, and the difference in value paid either by the tenant to the landlord, or by the latter to the former, as the case may be. It is the business of the garden-surveyor to estimate the value of the stock, crop, and business of nurserymen, and other tradesmen-gardeners, quitting or entering on premises, or purchasing or disposing of their establishments. The garden-surveyor is sometimes also a garden-auctioneer; but generally his business is confined to valuing, and practised by nurserymen or other tradesmen-gardeners.

7401. The tree-surveyor, or timber-surveyor, limits his occupation to arboriculture: he measures and values standing timber or copsewood; estimates the value of young plantations, the expense of forming them, of managing them during a certain number of years; of enclosing with live hedges of every kind, and their management till fence high: he determines what trees shall be felled, thinned, or pruned, and directs the manner of performing these operations.

7402. The horticultural architect (Planner, Scotch) gives designs for kitchen-gardens and flower-gardens, with their structures and buildings: he sometimes also lays out shrubberies and pleasure-grounds, when on a small scale. In this case he takes the title of ornamental gardener (Planner of policies, Scotch), or ground-architect.

7403. The horticultural artist is employed in designing and painting fruits, flowers, plants, implements, and horticultural structures and gardens, but chiefly in drawing fruits and flowers, the gardens and structures being more commonly drawn by the horticultural architect, or landscape-gardener.

7404. The landscape-gardener, or layer out of grounds; Artiste jardini, Ingenieur des jardins pittoresques, or Anglais, and Jardiniy paysagiste, Fr.; Garten künstler, Ger.; and Artiste giardiniere, Ital. This species of counsellor gives designs for disposing of the plantations, water, buildings, and other scenery, in parks or landscape-gardens, and generally for every thing relating to the arrangement of a country-seat, excepting the architecture of the mansion, offices, and other buildings; but in what respects the site of these, and the exposure of the principal fronts and apartments of the house, his counsel is required jointly with that of the architect.

7405. The gardening author may be considered the most universal kind of garden-counsellor, since his province extends to every branch of the art. The simplest variety of this species is the author of remarks, or an essay, or treatise on one particular plant or subject; the most comprehensive, he who embraces the whole of the science and art of gardening; but the most valuable, he who communicates original information.

Sect. IV. Patrons of Gardening.

7406. Every man who does not limit the vegetable parts of his dinner to bread and potatoes, is a patron of gardening, by creating a demand for its productions. He is a consumer, which is the first species of patron, and the more valuable varieties are such as regularly produce a dessert after dinner, and maintain throughout the year beautiful nosegays and pots of flowers in their lobbies and drawingrooms.
7407. _Amateurs_ (lovers of gardening). These promote the art by the applause they bestow on its productions, of which, to a certain extent, they become purchasers.

7408. _Connaisseurs_ (critical or skilful lovers of gardening). These promote the art in the same way as the amateur; but much more powerfully, in proportion as approbation, founded on knowledge, is valued before that which arises chiefly from spontaneous affection. By the purchase of books, engravings, and drawings, from which, in great part, this species of patrons acquire their knowledge, they may be said to be eminent encouragers of counsellor-gardeners.

7409. _Employers_ of gardeners, whether of the serving, tradesman, or counsellor classes, are obvious and undoubted patrons of the art.

7410. _Occupiers of gardens_ of necessity employ both serving and tradesmen gardeners, and when they are amateurs or connaisseurs, are often great encouragers of the art; for every one is not so fortunate as to rank among the

7411. _Proprietors of gardens_, who are the most eminent of all patrons, promoting every department of the art, and employing serving, tradesmen, and artist gardeners. A man whose garden is his own for ever, or for a considerable length of time, whether that garden be surrounded by a fence of a few hundred feet, or a park-wall of ten or twelve miles, will always be effecting some change in arrangement, or in culture, favorable to trade and to artists. "I pity that man," says Pope, "who has completed every thing in his garden." "Après mes enfans et deux ou trois femmes que j'aime, ou crois aimer à la folie, mes jardins sont ce qui me fait le plus de plaisir au monde; il y en a peu d'auussi beaux." (Mémoires et Lettres du Prince de Ligne, tom. i. 117.)

---

**Book I. BRITISH GARDENS. 1043.**

**CHAP. II.**

Of the different Kinds of Gardens in Britain, relatively to the different Classes of Society, and the different Species of Gardeners.

7412. In order to form an estimate of the importance of gardening to a people, and of the duties of gardeners in filling different situations, it is not only necessary to notice the different species of gardeners to which it has given rise, but also the different kinds of gardens; the classes of society which enjoy them; and the species of operators and patrons who cultivate and encourage them. In this view, gardeners may be arranged as private, commercial, or public establishments.

**Sect. I. Private British Gardens.**

7413. Of _private British gardens_, the most numerous class of gardens, and those the most regularly distributed over the British isles, are those of the country laborer, or what are usually denominated _cottage-gardens_. Next to his cottage, the laborer finds his garden the most useful and agreeable object, by supplying a part of his food, affording an agreeable source of recreation, and presenting an opportunity of displaying his taste in its cultivation. To the laborer who has no cottage or garden, human life presents no hopes; his future extends only to a few days; he has no consolation but in the contemplation of fixed wages, which the most fatiguing exertions can in no degree increase, and of which, in the case of illness, he has only the amount of a week to interpose between the absolute want of lodging and food. But the laborer who rents a cottage and garden is secure at all events of a roof to cover him; he can multiply his pleasures and pains by the addition of a wife and children; and he knows that he can live for a certain time on the produce of his garden. By these hopes he is consoled. Besides, he has that most desirable object, something that he can call his own; and is thus enabled to participate in the feelings which belong to the love of property and progeny—feelings often, indeed, mixed with pain, but which nevertheless, have been an object of ambition from the earliest ages of the world.

7414. _Cottage-gardens_, in a moral and political point of view, are of obvious importance; attaching the cottager to his home and to his country, by inducing sober, industrious, and domestic habits; and by creating that feeling of independence which is the best security against pauperism.

7415. The _extent_ of the garden of a laborer ought never to be such as to interfere with his employment as a laborer; unless it is sufficiently so to enable him to dispose of part of the produce in the manner of a market-gardener; or to keep a _cow_ and dispose of her produce. But as it will rarely happen that in either case he can compete in the market with the regular market-gardener or farmer, the most useful extent of garden is that which shall occupy his own leisure hours in the operations of digging and planting, and those of his wife and children in hoeing, weeding, and watering. This will generally, as already stated (746), be something between one eighth, and three sixteenths of an acre, including the space on which the cottage stands.

7416. The _vegetables_ which may be most profitably cultivated by the occupants of this description are, cabbages of the early heading sorts, hardy borecoles, as the German greens, early potatoes, parsnips, tur-
nips, carrots, onions, leeks, peas, beans, and kidneybeans; a plant or two of celery (not to be blanched), thyme, mint, and chives for seasoning; and a few plants of rhubarb for tarts.

In a cottage-garden, which ought to be omitted, are the gooseberry, and black and red currant, as standards, in the margins of the plots, or against the walls or pales, if the garden is surrounded by these: the kinds of gooseberry should be those which grow with straight upright shoots, as the Manchester, the Scottish, the Craven and the Wiltshire sorts, and the yellow globe, which is the most useful, and the yellow currant, and the red gooseberry, and the red currant, as standards, which might be added, and the damson, bullace, and wineplum sorts; the may-duke cherries, or yair, and a winter berry may be added. If the coast is favorable, the most southerly sides of the house may be covered with a white muscadine, or black July grape, or otherwise with pears in the best aspects, currants in the worst, and a rose and honeysuckle on the porch. (See 7310.)

7418. In the management of cottage-gardens, no opportunity should be neglected by the cottager of collecting manure from the highways, from the grass, weeds, and mud of ditches and lanes; leaves of trees, sot-ashes, and all household refuse, should be collected, and the whole mixed together in the dunghill (1977.), and turned frequently over before using. In the culture of these gardens, the principle of a change of surface (2549.), and of a rotation of crops (2556.), should be attended to; and also that of continually stirring the soil among growing plants as deep as possible; of watering in dry weather, regularly every evening, and of gathering by hand all worms, snails, slugs, grubs, and other insects, as soon as they appear. Of potatoes only the early sorts should be cultivated in the cottage-garden, because that plant is now so generally a subject of field-culture, that for a main supply the cottager will find it cheaper to purchase from the farmer; or to rent a few square yards of a field devoted to drilled green crops, and cultivate himself as many as may serve his family and his pigs and poultry. Besides, in either of these ways, he is more certain of obtaining potatoes of good quality, as even though the sorts be changed, still the quality is much deteriorated by repeated culture on the same spot.

7419. Improvement of cottage-gardens. It would be a most desirable circumstance, if proprietors who keep head gardeners would desire them to attend to the gardens of the cottagers on their estates; to supply them with proper seeds and plants; to propagate for them a few fruit-trees, and distribute them in the proper places in their plots; to teach them modes of culture suitable for their circumstances; and to enforce them by adequate motives of hope or fear, of reward or removal, as the case might require. In this way, at no additional expense whatever to the proprietor, much happiness might be diffused; and constant recurring objects too often indicating wretchedness, or at east slovenliness, rendered useful, neat, and even ornamental.

7420. Domestic improvement of cottagers. It would also be a very desirable circumstance if some of the female servants, or even some of the charitably disposed females of the family, would instruct the cottagers' wives on their estates in improved modes of cookery, washing, making, and mending. It is astonishing how ignorant and how extravagant the humbler classes are in these respects; it is rare to find in operation any principle of action, or much regard to economy in domestic management. It appears to be all work at random, from the making of soup to the baking of pastry. Much might be done by taking any one cottage's dish, and cooking it in different ways before her. For example, soup from vegetables, water, and a little butter only. How different that made by merely boiling the ingredients as before mentioned! burning to butter; adding the butter to the lumps of the soup, and half a lea of green celery! How few cottagers know how to make the most of their bees, which, besides honey, afford a most refreshing and enlivening drink, little inferior, when properly made, to champagne. Man, in the condition of a day-laborer, is generally so much engaged in procuring the raw materials of his livelihood, that he has little leisure to make the most of the provisions necessary for manufacturing them into the best fabrics. But let him once be properly instructed in this matter; let him once feel the enjoyments of which, even his condition of life is susceptible, and he will not easily afterwards engage in the state of labor and servitude, man is generally so stupid, that almost every degree of refinement, or sensation beyond that of mere animal feeling, is lost on him. The rich man is happily willing to put his hand in his pocket to help him; but that merely affords a temporary relief from evil. To supply instruction in plain practicable economy, and patiently to follow it in it becomes a habit in the cottager to effect any economical improvement in this condition of life, which will be felt by the subjects of it during their lives; and being transferred to their posterity like other habits and customs, must ultimately ameliorate this most numerous and efficient order of society.

7421. Supplying economical knowledge to cottagers. Something in the furtherance of the above ideas might be effected by the following, which is executed on the premises, and is ascertained by growing up in ignorance of them, without the habit of reading, does not readily receive instruction from books. His want of experience in book-knowledge prevents him from discerning what is practicable from what is speculative, and consequently he cannot both know the man who instructs him, and appropriate it to his use. The mind requires a certain preparation before it will receive new ideas; and its faculties must have been exercised on ordinary matters, before reason can be properly employed, on any subject not yet known. Tracts, therefore, among the laboring classes are chiefly useful to their children; and if children were taught the common labors and operations of husbandry and domestic economy at school, which they might easily be by the Lancasterian method of instruction, it would fit them for entering on a life of labor with superior advantages, both in point of performing their labor, and in making the most of its reward.

7422. The cottage-gardens of artificers, that is, of operative mechanics and manufacturers, small tradesmen, and other country artisans, differ from those of the common laborer in being somewhat larger, and in having a larger portion of the space devoted to the culture of fruit-trees and flowers. They are cultivated by the occupier and his family, and very frequently sufficient ground is connected with these gardens to enable the occupier to keep a cow or labor. These indeed are often half-starved animals, producing little benefit to their owners beyond the feelings of satisfaction which the idea of possessing them confers. In several parts, and especially the north of England, and generally in Scotland, the gardens of artisans differ from those of the cottager, in being held on a
long building-lease, and in being situated in or around large towns. The most remarkable gardens of this description for riches, order, and beauty, are at Norwich, where they first originated (1573.); at Spitalfields, near London, among the residences of the silk weavers; at Manchester, and other Lancashire and Cheshire towns; and at Paisley and Glasgow. The occupiers are generally their own masters, having their looms or other implements of trade within their dwellings, and being employed by merchant-manufacturers, or taking their goods to a common market. They are generally an industrious, industrious class of men, who take great delight in their gardens, and the point of practice in which they excel is in the production of florists’ flowers. Norwich is, or used to be, noted for carnations. Spitalfields is still noted for all the competition flowers, but especially for auriculas and tulips. Manchester for auriculas and polyanthuses, and also for the production of new varieties, and large specimens of gooseberries; and Paisley and Glasgow for pinks. The florists in Lancashire, indeed, excel in every branch of their profession, and are also famous for their success in cultivating the potatoe, which was in general use in this county long before it was known in many others. The artisans of Paisley are, perhaps, the most intelligent of their order in the world; even the speeches of what were called the radical reformers of this town, astonished by their argument and style; and the success of the florists, and the laws of their association, are not less surprising. (See Lancashire and Renfrewshire, in the succeeding chapter.)

7423. The farmer’s garden (7293.) varies in extent from an eighth part to a whole acre or upwards, according to the kind of farm. Lord Kames (Gent. Farm. 297.) considers a fruitful kitchen-garden as the chief accommodation of a farm; yet farmers in general pay very little attention to their gardens, even where the best systems of agriculture are preserved. They are managed in the smallest farms by the farmer himself, with the occasional assistance of his men, and of the female part of his family; in those of a higher kind, where the farmer is not personally an operator, they are managed by a laborer, who is generally kept on the farm for cleaning hedges, clearing out furrows, and doing such extra field-work as cannot be performed by the regular hands of the farm.

7424. In tradesmen’s farms, large, or what are called gentlemen’s farms, villa farms, and fermes ornées, the one or other of these gardens are common. The gardener, who is expected to assist in the field during the hay and corn harvests; and, therefore, he seldom ranks high in his profession.

7425. The products of common farmers’ gardens are of the most useful and handy kinds; but those of villa and ornamental farms contain hot-houses, and often produce many of the luxuries of regular villa or ornamental gardens. It is difficult, or even impossible, to excel in the management of this kind of garden, excepting landed proprietors, have an opportunity of indulging their taste so variously and extensively, and at so little expense. In the first place, supposing a farmer to have a lease for twenty-one years, at a free rent; whatever state he finds the farm in; if it be enclosed and subdivided, he may render it a fermé ornée, by leaving strips of pasture round all the arable fields, and connecting these by gates in such a way as that he may form a drive or riding (7580) round and through the whole. Secondly, he may form, or enlarge and arrange, the kitchen-garden, flower-garden, orchard, and the portion of lawn and pleasure-ground round or beside the farm-house, at pleasure. Thirdly, he may heat hot-houses, pits, and hot-baths, at the expense of labor only, by fermenting his farm-yard-dung in such pits as West’s (fig. 290.), in such vineyards as Anderson’s (fig. 461.), or in other vaults for pines (fig. 402.), or behind walls or pales, to force fruit-trees. Perhaps one of the simplest modes for a farmer to take the benefit of his fermenting dung would be the following. Take a large number of pales to serve as a wall for training on, hinged at the surface of the ground. On these, when placed in a position forming an angle with the ground of 45°, the trees should be trained. Then, when the dung is to be placed behind, the pales should be elevated to the perpendicular, and the dung dropped down in cart-leads, and laid up in a regular ridge, sloping towards the pales, but perpendicular to the ridge; the pales should then be turned back on the ridge; and the advantage of this plan over that of fixed upright pales would be, that as the dung sunk the pales would sink with it, and by always being in close contact, would receive more heat than by the usual mode, in which, when the dung sinks, it separates from the pales, and then the whole surface of the dung being exposed, the heat ascends, and is lost. But an exceeding good plan for every description of forcing or exotic culture, would be to construct houses on the plan of West’s pit, with all that part of the north wall under the level of the earth or floor for the pots substituted by cast-iron or stone pillars, and wooden gates between. These would facilitate the putting in and taking out of the dung, and, being shut close, no part of the heat would escape. These plans are only for amateur, or proprietor farmers, for the common commercial or market farmer could not devote either sufficient capital or attention to the subject. He, in general, leaves the care of his garden to his wife, whose taste and ambition does not direct her in this management; though a neat and well-tended garden, if it requires so very little attention (see 3041.), might often be added, in order to enhance the enjoyments of this class of society.

7426. Street-gardens, and the smaller suburban gardens (7287. to 7292.), are the next classes in point of number. They differ from the former in being always gardens of pleasure, consisting of a grass-plot (complot, Fr. a design or device,) with a border, or a few patches of flowers in front of the house, and a gravel-plot or grass-plot behind, sometimes substituted by a plot for culinary vegetables and small fruits. Their extent may be from an eighth to half an acre, and they are managed by jobbing-gardeners by the day or year. As the plants and turf are soon injured by the smoky and confined atmosphere incident to their situations, the finer plants and trees do not thrive in them, and the sorts which do succeed, and even the turf, require frequent renewal. Evergreens and early spring flowers, both of the tree and herbaceous kinds, are most to be desired as permanent plants for these gardens; and in summer a display of annuals is made from transplanted plants furnished by the jobber, whose great object ought to be to keep up a succession of flowers, and to keep the grass and gravel in order, and the whole perfectly neat.
7427. Tradesmen's villas (7284.), of the smaller kind, may contain from a fourth part to a whole acre, and are commonly managed by a sort of hybrid gardener, who acts also in the capacity of groom, or of house-servant. On a larger scale they are managed by master gardeners of the lowest kind, as from such situations they can seldom rise to be head gardeners. Besides attending to the duties of the jobber, as to suburban gardens, the citizen's gardener ought to study to procure early and late crops of the vegetables most in use; as peas, kidneybeans, potatoes, turnips, &c., because at these seasons they are dear to purchase. Main summer crops are of less consequence, as they may be procured cheap at market. For similar reasons, he ought never to be deficient of salads, pot and sweet herbs, tart plants, &c., as these are dearer to purchase in proportion to other vegetables, because less in demand. If there are frames, hot-beds, and hot-houses, the same general principles are to be observed, viz. when the whole of what is necessary for the consumption of the family cannot be raised, to raise such crops as, whether from their kind, or the seasons at which they are grown, are most dear to purchase.

7428. Where amateurs of gardening have gardens, they are generally cabinets of rural beauty, however small. We may offer as examples that of R. A. Salisbury, Esq. which consists entirely of plants in pots, which fill a court of a few yards square in Queen-street, Edgeware Road, London; and that of Topham, of Elkins's-row, Bayswater, which is not much larger than that of Salisbury, but in which the choicest flowers are sunk in pots, and changed whenever they begin to fade. This garden is a speck of perfect beauty in its kind. There are a few plots round London similarly treated, and but a few. On a larger scale are numerous amateur gardens; that of the Comte de Vande, at Bayswater, contains two acres, and is remarkable for its botanical collection, its standard roses, and the neatness with which it is kept: but the plan of the garden, its cul de sac walks, ill proportioned borders, and paltry boundary fence of poles, spoils every thing.

7429. The gardens of connoisseurs vary in extent; perhaps the largest and best furnished is that of Knight, the first of all horticultural connoisseurs, at Downton Castle, which, with the experimental ground, contains several acres, and various hot-houses, pits, and frames. In general these gardens are to be considered as horticultural workshops, and beauty and order is not to be looked for. Regular gardeners are very seldom employed. Knight says (Hort. Trans. iv. 17.), "My gardener is an extremely simple laborer, he does not know a letter or a figure." One horticulturist with whom we are acquainted, employs only women; another, only boys; and several do all the work themselves.

7430. Suburban or citizens' villas (7285.) may be considered as occupied by a more wealthy class of citizens; or if not more wealthy, possessing more of the taste and ton of good society. These gardens or residences contain always a portion of lawn or field, as well as a kitchen-garden and shrubbery, and may extend from one to ten acres. They generally contain hot-houses of some kind, and are managed by a regularly bred master-gardener. Besides attending to the duties of a tradesman's gardener, he must bear in mind two things; first, as the families who occupy such places are generally constant residents, he must provide enjoyment both of the agreeable kind from the flower-garden and plant hot-houses, and of the useful kind from the culinary and fruit-garden, for every month in the year; and secondly, he must attend to the habits of the family as to the kinds of productions and enjoyments preferred. The great art of deriving enjoyment from a country-residence of this description, is to provide an interest, a hope, and a fear, for every season, or even for every month in the year. By observing the chapter of monthly productions of horticulture (6038.), and the table of monthly floricultural productions (6741.), the resources which these branches afford are readily discovered. There are also other resources in the nature of culture; such, for example, as raising flowers or fruits from seed. In this view it is good to have some seedlings of early and late flowers, as of the polyanthus and dahlias; of early and late fruits, as of the currant or strawberry, and apple, to come into flower and bearing every season. Other devices for exciting and keeping alive interest will readily occur to the reflecting gardener.

7431. With respect to the habits of a family, it is not only the duty of a gardener to grow those vegetables, fruits, and flowers, of which the members consume the most, or of which they are fondest; but he must also look for other habits of enjoyment; as whether they are fond of walking in the garden, and at what times and places, so as to have every thing in the condition and order best adapted for those purposes. Some delight in smells, and for such, the most odoriferous plants should be distributed along the walks; others in sounds, and for these, the trees and plants which produce the fruits preferred by singing birds should be planted; or birds, in portable aviaries, distributed through the grounds. Some, in walking, may prefer not being seen by workmen, or at least not meeting them in the paths on which they enjoy this mode of recreation; others may take delight in seeing work going forward, and even in asking questions of the operators.
7432. In all families there are invalids at some time or other, and a great object is to render the garden an alleviation to their sufferings. Some afflicted in the lower extremities can only walk on grass-walks; others, from asthma, may not be able to stoop to smell to or gather a rose or a gooseberry; others may require to be carried round the hot-houses in a chair, or wheeled along the walks reclining on a couch, and covered with a glass case. Grass-walks, standard roses, and gooseberries, elevated pots of plants, hot-house paths uninterrupted by pots, and gravel-walks smoothly rolled, are obvious luxuries for such persons. A sick horticulturist, confined to his chamber, may derive some enjoyment from having pots of plants brought before him for a few minutes, to show him their progress; and also by relations of what work is going on, and what articles are vegetating in the garden. When life is under the pressure of disease, any object or measure which can divert the attention for a moment affords relief; for though night cannot be turned into day without the presence of the sun, its darkness may be lessened by a speck of the dimmest day-cloud. It does not often happen that residences are laid out purposely for invalids; but where this is the case, the designer ought to contrive gently inclined planes instead of steps or stairs, and to avoid all corners in walks and paths. Easy turnings in walks are also a great luxury to studious persons, who think as they walk. For this reason, an author, if he can afford any other garden than a pot of mint, should surround his plot with an oval path, that he may walk on without end, and without any sensible change in the position of his body.

7433. Whether a family is of retired or public habits ought to be noticed by the gardener. A retired family will derive most satisfaction from the useful products, and the personal recreation they can take in their garden. A public or fashionable family, on the contrary, from its beauty, high order, and keeping. Beautiful objects are formed to be admired, that is their use, and what renders them so desirable, and their possessors so much envied; therefore those who possess beautiful objects in order to derive the enjoyment they are calculated to confer, must court applause by inviting such friends as are likely to become admirers. Let no man shut himself up in the midst of beautiful rural nature and think he will be perfectly happy, lest he should be forced with the satirist to ask —

"What is nature? ring her changes round,
Her three flat notes are water, plants, and ground."

7434. To be condemned to pass an eternity in a pleasure-ground, would be perhaps as dull as to pass it in a convenicle. Man is a social being, and never can reject the habits to which this part of his nature gives rise with impunity. To be happy he must see and be seen: it is the operation of this principle that has rendered the most beautiful seats of the country show-places, or places which all the world are invited to come and admire, as Blenheim, Mount Edgecumbe. Hackfall, &c.; which induces others to publish accounts of their seats, as Dr. Letsom of Grove Hill, the late T. Johnes, Esq. of Hafod, &c.; which leads the citizen to place his box or lodge, and the artisan or laborer his cottage or cabin by the roadside; and which, in short, impels the humblest individual to court applause by making his powers, either of purse or mind, known to those around him. A gardener, therefore, must attend to these general principles of our nature, and apply them in his department as well as he can; for much, it is evident, depends on his studying the effect of the scenes under his charge, and keeping them in the most perfect order and neatness for inspection.

7435. Villas. (17278.) The grounds and gardens of this class of residences may occupy from ten to a hundred acres, or upwards; they are generally managed by a head gardener, with one or more journeymen, and probably an apprentice, and with the occasional assistance of men and women laborers. The kitchen and flower gardens of places of this sort are generally good, and well furnished with hot-houses; the shrubbery also is carefully laid out, and planted with choice shrubs and trees; and as the proprietor is generally an opulent commercial man, he is liberal in his annual expenditure. The gardeners at such places are generally well paid, no limits put to the dung, implements, structures, or assistance they may want, and left more entirely to their own discretion than those in the service of country-gentlemen. Their responsibility is, therefore, so much the greater, and they are quite unpardonable if they do not excel in their art, and, above all things, in keeping the whole scene under their charge in the utmost order and neatness. It frequently happens, however, that soon after a gardener has got into such a situation, and become familiarised with his garden, and the habits of his family, he begins to consider his place as a sinecure (sine, adv. and cura; i.e. without care), and instead of ardently endeavoring that the productions of the current year shall surpass those of the year past; instead of adding more and more to the enjoyments of his employers, he begins to try with how little they may be put off; and the object of his ambition, which ought to be to delight and astonish his family, is ultimately lowered to that of contenting them. This sort of lethargic indifference, brought on by plenty and ease, is not peculiar to gardeners; it is a condition of our nature, which also furnishes checks to its increase after a certain
The simplest check to indolent gardeners is the demands of their masters, who seeing at other tables, and in other gardens, productions superior to their own, and knowing that they spare no expense, &c., naturally enquire into the cause of the default. This sort of observation when abroad, and comparison with home, ought never to be neglected by those who wish to keep servants of any description to their duty. The deficiencies and bad points of other gardens and gardeners may be let alone; but their excellencies should always be particularised, and dwelt on to our own; and where a failure happens in the one case, the reasons required for the other's superiority in that particular, and our inferiority. If the master ultimately becomes dissatisfied with the condition and produce of his garden, let him first call in the nurseryman who recommended the gardener, as counsel for both sides; and let him consign him to this nurseryman, with such a character as he may be considered to merit.

On the order and neatness with which a garden is kept, so much of its beauty and effect depends, that often as we have mentioned the subject in the course of this work, we must again advert to it. Many excellent gardeners are deficient in these particulars, from causes which, at first sight, would seem calculated to have a contrary effect; such as staying constantly at home in their own gardens, and daily inspecting every part of them. The consequence of this is, that the changes which take place in the growth, decay, or deterioration of objects is so gradual as not to be observed, and that an object seen twice every day for ten days, seems the same thing the twentieth time which it did the first, when, in fact, and to the person who has only seen it two or three times, it is something different. To illustrate this, let us suppose a collection of green-house plants, newly shifted, surfaced, pruned, trimmed, tied, washed, and replaced on the stage, and that one man attends to the watering of them regularly every day for a month. They are newly shifted plants the first day, and consequently require nothing done to them; so they are the second, third, fourth, and so on, even after a week or ten days they are so considered, and this notion now becomes habitual to the attendant. Every day as he enters the green-house to water, he sees, without even opening his eyes, (that is, the idea recurs,) a stage of newly shifted plants, all fresh, and free from weeds and decayed leaves, and wanting nothing; therefore weeds and decayed leaves he never thinks of looking for, but waters on; whilst a stranger, or one who has not seen them for a few days, is struck with the slovenliness displayed, and though perhaps the same thing may take place in his own garden, or his own department in the same residence; he goes away not willing to benefit the other by corrective advice, but "thanking God he is not like this man."

This cause of slovenliness we think there are few gardeners who will deny to be correctly stated; and we think, the cause being discovered, the remedy very easily presents itself. Let master gardeners not inspect every part of what is under their care every day at the same time, and in the same order, but let them omit some parts on some days, occasionally omit the whole, and often vary the time and order of their visits. Let them also, instead of going round to look if such and such scenes are in order, go impressed with the idea of finding them in bad order, in search of particular sorts of weeds, of decayed, damaged, or straggling parts of plants, insects, &c. It may seem ludicrous to add, let him go round sometimes in the night instead of during day; but we are persuaded that viewing particular scenes by the light of a lantern or the moon, would present them in such a new aspect, as would probably show deformities or deficiencies. It is a common observation of servants, that after their master has been a day or two confined with illness, or on the morning after an evening of dissipation, he is generally very apt to find fault and be cross, and difficult to please. This is actually the case, and is satisfactorily accounted for without reference to humor or temper: the master sees faults which before escaped him, because the machinery of his faculties has been deranged, and he sees differently. But why does he see faults rather than beauties? Because it is his business to seek for them, and this impression being habitual on his mind, the strongest images reflected by the eye are of that nature.

Visiting neighboring gardens is another important part of a head gardener's duty. This should be done with a view not only to order and neatness, but also to good culture, intelligence as to the state of gardening, &c.; he should not limit his visits to those near him, but include all the principal gardens for forty or fifty miles round; and he should, at least, once a year, visit the capital or the metropolis, to inform himself, by means of the nurserymen, and among the numerous first-rate gardens that are always found round capital cities, the horticultural societies, and agricultural libraries, of what is going on in the gardening world.

The mansion and demesne is less common than the villa near large towns, but more so in the country. The proprietors are sometimes commercial men, but more generally country-gentlemen. Their extent varies from a hundred to a thousand acres,
or upwards, and, in addition to the park and gardens, they contain a home or family farm managed by a bailiff. The garden-scenery, as in the case of a villa, is managed by a head gardener, sometimes more circumscribed in his operations, but always respectively provided for, both as to his person and garden. The worst point attending residences of this description is, that the business of gardener and bailiff is, sometimes in England, and often in the other districts of the empire, united; and the consequence almost universally is, that the business of both situations is very imperfectly performed. The master's object in attempting this union is obviously the saving of a bailiff's wages, which, it is allowed, is an apparent saving, though certainly not always so ultimately. The gardener and bailiff cannot be present at one time, both in the garden and on the farm; he must pass alternately from the one to the other, and it may be questioned whether the time lost in his absence from both, while going between them or at market, and from the one while on the other, does not more than counterbalance the wages of a bailiff, independently of any other consideration. But the loss both to the farm and garden, in cases of this sort, though not very obvious at first sight, is very considerable when details are entered on. No man brought up as a gardener can at once become a good bailiff; and admitting that he may become one in time, yet he acquires his experience at his master's expense. It is generally imagined that a gardener makes a good arable farmer; but this he does not become without experience; for though he may know what good culture is, and may bring the fields of corn or green crops under his charge into a state of good cultivation, yet he may do this at much too great an expense to afford any profit. But the management of arable land is but a small part of a bailiff's duty; the grand object is the breeding, rearing, fattening, buying, and selling of live stock; and a knowledge of these parts of farming cannot be acquired under several years' experience. In the mean time, the losses to the master by bad marketing must be most considerable. Suppose the gardener and bailiff goes to purchase a few scores of sheep, and a dozen of oxen for feeding, every grazer knows that on the nature of the feel alone, which no man can communicate to another by description, much of the value of the animal depends. But a gardener knows nothing of this feel, and the tact of discovering it is not to be acquired but after such a course of experience as no prudent master, who knows any thing of the subject, would wish a bailiff to acquire in his service. As much might be said on the correctness of judgment required in selecting animals to breed together, and in the shrewdness required for marketing; the latter, a duty totally inconsistent with the retired habits of a gardener.

7441. That some gardeners may become good bailiffs we readily allow, because a man of moderately good natural faculties and persevering application, will acquire any thing; but from the nature of the duties which a bailiff has to perform, and the time he must occupy on the farm and at market, it is impossible he can attend sufficiently to the garden. We have never yet known an instance where the duties of both the offices were well performed by the same person, but almost universally found both the garden and farm deficient in the products expected from them. That the master is content is no proof to the contrary, for knowing no better, he naturally considers what he has as the best.

7442. From the country-gentleman's gardener, who does not unite the duties of bailiff; a good deal is expected; he must know his profession well; he cannot probably from limited extent and means produce all he could wish, or that a garden should afford, but what he undertakes to raise he must raise in perfection, according to the kind and season, and the main crops in sufficient quantity, because he cannot, like the citizen's gardener, have recourse to Covent-garden, nor like the villa-gardener, surrounded by neighbors, borrow from them melons, mushrooms, or asparagus, in cases of emergency. He has one duty also which does not belong to either of these classes of gardeners, that of packing and sending fruits and other garden products to town when the family reside there.

7443. The mansion-residence may be considered as including all those between the villa and the royal palace. The dwellinghouses are called houses, halls, courts, or palaces, according to the custom of the country, where they are situated; or castles, abbey, or Grecian buildings, according to their style of architecture; and mansions or palaces, according to their extent and magnificence. The mansion-residence consists of the same parts as in the mansion and demesne (7270.); it may contain from five hundred to ten thousand acres, or upwards, and the whole is managed in the first-rate establishments by the following officers: — A secretary, who receives the commands of the master, and conveys them to the house-steward, who manages the expenditure of the house and offices, and gamekeeper; to the land-steward, who manages the tenanted lands, receiving rents, and seeing to the fulfilsment of covenants in leases, repairs, &c.; to the bailiff, who manages the family farm; and to the gardener, who manages the garden-scenery, including the park, as far as respects the trees and grass, and the internal plantations or forests.

7444. The gardener who occupies a first-rate situation has under him a forester, for the demesne-woods and park-trees; a pleasure-ground foreman for the lawns and shrubbery; a flower-garden foreman, a forcing-department foreman, and a kitchen-garden foreman. A horse and two-wheeled chaise is kept for his use, by a boy, who also acts as his messenger and house-servant. He lives in a respectable house, near the kitchen-garden, with a stable and cowhouse not far distant. His wages are from 150l. to 300l. a-year, independently of a free house, fuel, and other advantages. He should be at the head of
STATISTICS OF GARDENING. Part IV.

7445. Some idea of the extent of the duties of a head gardener who fills a first-rate situation, may be had from the chapter of monthly horticultural productions, the table of floricultural productions, and arboriculture and landscape-gardening, as treated of in this work; and therefore all that we shall attempt here, in addition to what has just been offered on the subject of the duties of gardeners holding inferior situations (7426. to 7442.), is to enumerate a few of the expedients, some of them common and others uncommon, which every description of gardener will have occasion to practise more or less but which more particularly demand the attention of gardeners of the highest class, who, not engaging in expense, are expected not to be deficient in producing all the comforts and luxuries that a garden can afford. We shall arrange these hints under the four departments of practical gardening.

7446. Expedients and anomalous practices in the horticultural department.

To have early crops of herbageous vegetables in the open air. Sow in pots in spring, one seed in a pot, if the soil be fertile and the situation suitable, place them in a gentle hot-bed, shift into larger pots as they grow, and when all danger from frost is over, transplant with great care, into the finely pulped rich soil of a warm border. Peas, beans, turnips, potatoes, carrots, sauerkraut, and saplings may be had very early in this way.

The rose is very scarce, and a great quantity is wanted for hot-beds and pots. Collect the spray of trees, cowpeas, and hedges; cut it into lengths of three or four inches, with a sharp knife; then, when the dups, or saplings, are dry, strip the old shavings, flax-dressers refuse, leaves, reeds, rushes, peat, moss, heath, or any substance capable of undergoing the putrescent fermentation.

Tinture bark is scarce. Add spy, furze, or heaths, charged with the saw-cutter to the length of the chips of bark, also chopped shavings of wood, parchings of leather, &c. Candles and old flax-seed, carduus acanthus, and in the management and onions have failed. Sow early in spring single seeds in small pots, and found transplants in the warmest situation when all danger from frost is over.

To forward early seedling crops. Sow in the usual way under cloths or frames, when all danger from frost is over. Peas, spinach, and turnips, may be had three weeks earlier than usual by this practice.

All your ground is cropped, and some crops not likely to be removed in futurity, which are immediately to succeed them, to get in in season. Forward the succeeding crops in pots, and as soon as the preceding crop is removed, transplant with the bare roots.

The garden is too small for the culinary productions. Forward the cauliflower tribe in pots, and only plant them in the compartments. Instead of hot-beds, which occupy much horizontal space, have cucumbers and melons in hot-beds covered with cloths and other creasins, as love-apples, New Zealand spinach, gourds, &c. on upright trellis-work or pales, the potatoes may be raised on hoops or wheatsheaves, currents, and all dwarf trees as espaliers.

Bore in fruit not approved of. Espalier or graft other sorts. You have some excellent sorts of peaches or other soft tree fruits, which you wish some person to taste at a distance, too great or too small, either to the north or south, or in any sem-beds either in spring to be scallop-huddled, when they will produce their fruit the same year, or in the usual beds of gravel-walks and cages.

Trees old and not productive. Head down and renew the soil, and the rest will thrive. To have late crops of asparagus lie anes. Plant the latest crops in large pots or boxes, keep them plunged in the open air, and remove them when there is danger of frost to any of the forcing-houses not in operation. In damp weather, light gentlemen prefer the greenhouse, in stormy and dark weather, light gentle fires at night. In this way peas, beans, kidneys, cauliflower, spinach, &c. may be had in a good state till January or later.

The frames or fists of a house or in action are suddenly covered during a severe frost. Distribute pots of burning charcoal or peat over the floor or paths of the house, and cover the glass with paper or cloths.

To lessen the danger of the sun scorching plants in hot-houses or hothouses. Distribute pots of burning charcoal or peat over the floor or paths of the house, and cover the glass with paper or cloths.

Grafts of fine fruits are received, for which you have no stocks, and may make them yourself. Dig up some roots of trees of the proper kind, and make stocks of them; graft the 'em, and in Knight's manner of sprouting, and after a season, make stocks of them. Never forget that grafting and buddling may be performed at any season of the year, (though best in certain instances,) and on hawthorns as well as woody plants, on roots and tubers as well as stumps, stools, and ligustrum shoots.

Cooking the potatoes by putting them in a stove or oven, and then you may dry and make them as fresh as second-year plants of asparagus lie anes. Plant the latest crops in large pots or boxes, keep them plunged in the open air, and remove them when there is danger of frost to any of the forcing-houses not in operation. In damp weather, light gentlemen prefer the greenhouse, in stormy and dark weather, light gentle fires at night. In this way peas, beans, kidneys, cauliflower, spinach, &c. may be had in a good state till January or later.

Never forget that grafting and buddling may be performed at any season of the year, (though best in certain instances,) and on hawthorns as well as woody plants, on roots and tubers as well as stumps, stools, and ligustrum shoots.

Cooking the potatoes by putting them in a stove or oven, and then you may dry and make them as fresh as

7447. Expedients and anomalous practices in floriculture.

The gravel walks are overgrown with weeds; a large party is expected, and you wish to give the roads a fresh and good appearance. Water them with water impregnated with pitch, or with a small quantity of soda, but be careful of the natural color of the gravel may be yellow or brown.

The natural color of the gravel is deficient in singing birds. Distribute cages of Canaries and other birds in song, hanging them on the trees in numbers, in some degree covering them with cloth. The flower-garden and shrubbery deficient in odoriferous plants, to produce an immediate remedy. Distribute pots of tansy-root (or any other herbaceous plant,) containing the ends of sprigs of sweet-grass, birch, balsam- poplar, and other trees, and any other plant you think not to be conspicuous, and renew them as they decay.

To forward the development of young seedlings by occasional or daily dry weather. Sprinkle odoriferous plants with the water-engine.

A large party is expected at a particular time; to give freshness and odor to the whole flower garden. Sprinkle every part with water, excepting the walks; if with rose-water, which may be made at little expense where there is extensive shrubbery, and kept for sprinkling the hot-houses; so much the better.

You expect a large party to visit the plant hot-houses, and they have been furnished with tobacco the night before. In one instance, they furnished with tobacco, as the spruce and silver firs; in another, sprigs of broom in another, verless trifolium, ragwort, leaved brasses of acorus calamus, and so on; then sprinkle with bran, you may not wish to give water the whole water with rose-water, but a little musk, orange-water, or other artificial odors.

Some house plants are very unsightly from accidents in plants, vases, or other causes; or from the want of water, or them at a particular hour. Contribute to have them filled with some common household water, or even a little spruce-ale, by pots near the eye; which, by the attraction of the spongy part of the plant, will not only retain the eye, but perhaps ease the pressure of the disease, and to estimate what is concealed by what is seen.

After a dry summer, your lawn is covered with a black hedges, on account of the smallness of the soil, it is desired to have a temporary green appearance. Water those places with those as a body.

A large number of green-house plants ordinarily argy, and no house is ready to put them into. Place poles against a south
wall, and place the ashes of your spare hot-beds over them to
Form temporary jogs of water. Procure one or any number of
A horse, which may hold from
six to thirty, or fifty gallons or upwards: let each vessel have a
tube reaching from what is to be its top within an inch of its
and also a stopcock. The vessel being filled with water,
and not being able to be removed, the air being
powerfully condensed, then turn the stopcock to prevent
the water running through the needle and in on the
nose for the jet. All is now ready for operation, and
the vessel may be placed in the situation where the jet is
desired to be made, in an inch from the soil or
makes it, and lastling in joint proportion to the quantity of water con-
tained in the vessel, the orifice of the jet, and the compres-
sion given to the air. This principle admits of great variety,
extension, and modification, and might be made to produce
very splendid effects; and through these effects would be but temporary, and would not
be more permanent than a strong wind, as in this climate, already cold and moist, the constant play of
jets of water is by no means desirable.
To produce a perpetual show in the gardens, in the hot-
houses, or near arbours, seats, &c. Place Zolliam hares in proper
situation for this purpose.
To dispense an agreeable odor suddenly and powerfully. Charge
one of these vessels with some of the flowers and
some of the odor in the form of oil or essence, &c., then
produce the discharge at the proper time and place, or charge
with resin or asphaltum, &c. (See 40.)
To direct a stream of destinated air against insects in hot-houses at
a distance from the path. Direct the stream through a long
thin tube, or charge a jet-vessel with the smoke or air.
To apply a vessel of water and steam or smoke. Use a brush or
stirch, dipped in water, or placed in the vessel.
To recover plants in hot-houses injured by frost. Shade two or three days, or
the plants will recover themselves, and keep the temperature very little above
the freezing point.

7448. Expedients and anomalous practices in landscape-gardening.
To render a dull part of the park more interesting. Build a
hip-stack there; or erect a shelter for cattle; or on tem-
porary occasions pitch a tent; or place a portable hay-rack
or arbour, at a distance, and attract deer or cattle to
send some men to work on the spot.
To vary on an extraordinary occasion a dull, uninteresting part
of the horizon. Cause a fire to be lighted of green wood, or
such materials as by the ascending smoke will break the line
in the proper place.
To vary for a few seasons the frost of a mass of wood. Disband
one of the lines of the trees, and when dead they will produce a break. For a few weeks;
cut back the winter's branches, and let them
remain on, or water with the engine and lime-water.
To give an idea of the effect which a piece of water in a particular
place will have on the landscape, erect a hill of
shape, and water the surface with lime-water; when dry the
scene will have the appearance the observer might expect.
To show the aftereffects of the effect of a great-walk in any par-
ticular place. Mark it out, and water with lime and yellow
ochre.
To show the effect of trees. Use poles with crosses at top, or
high stools, or plantations, as plantings of plantations.

7449. Expedients and anomalous practices in arboriculture.
A quantity of valuable trees arrive at a distance, very much
injured and dried up, and too late for planting in the usual way.
Immerse in water, or bury entirely in earth; then puddle and
water as ordinary, and for the reason to any part of the
nursey; or plant in pots, and place those on heat, when ready
they may be transplanted.
A violent wind has blown down a number of trees. Lop their tops,
and prune and arrange their roots, replacing them upright;
the wind's effect much milder than many others.
A handsome tree has lost some branches on one side, or is disfigured
by the removal of another tree. Try and arrange the branches
by cords or strong wires, as is done in green house plants
with their thrips.
To cover a tree rapidly with creepers. Place leafy boughs of
earth, containing plants of the sort of creeper desired, here and
there on the trunk and principal branches; tie them flat to
the tree, so as they may not appear conspicuous.

7450. To some of these expedients it may be objected, that they are deceits or temporary
tricks; but if they are so, they are in the spirit of the scenery to which they belong, and
they are calculated only to produce pleasure, not pain to any one; none of them are falsehoods,
or calculated to make a thing of one nature appear to be of another. We have not
directed the display of artificial fruits on wall-trees, of the fruiting of orange-plants from the
shops, of milliners' flowers in green houses, or living figures placed on pedestals as
statues, of fountains in mourning by making them run out ink, of altars and temples,
with persons in proper costume sacrificing on them, of mock buildings or animals, scops or
painted perspectives; all which and other deceptions are recommended and practised
by the French and Dutch.

7451. Gardens of royal palaces. The government-gardens of this country are those of
Windsor, Hampton Court, and Kensington; that of Kew being a private royal garden.
None of them are in any respect worthy of their rank; the garden at Windsor is without
hot-houses; that at Hampton Court consists chiefly of some pine-pits and a vineyard; at
Kensington, great part of the kitchen-garden is cultivated by the plough, and the only
two things which render it worth notice are its pine-stoves, and the public gardens or
pleasure-ground. The garden-structures at Kew are in a state of decay, and the gardens
are never in first-rate order, often slovenly, and always confined as to arrangements.
It is said these things arise from want of funds; and from the low rate at which the oper-
ators are paid in these gardens. This seems to be the case, and it is much to be regretted,
as it prevents the royal gardeners from displaying their skill and taste. Judging from
the pine-apples grown in the forcing-departments at Kensington and Hampton Court,
there is reason to believe this would be highly creditable to themselves, and exemplary to
the nation.

7452. The royal gardeners were formerly much consulted by private gentlemen on the
subject of their profession: this is still the case, though in a much less degree, and more
now as to garden structures or culture, than as to matters of design and taste. With
reference to this circumstance, the professional skill of royal gardeners ought to be the
first of the order, as their opinion will always be law to a certain number of the court; but
for the culture and produce of the gardens (situated as these now are), less professional skill
is wanted in a royal gardener than in a private head gardener, as deficiencies in products
can always be made up from the commercial gardeners, or from Covent-garden.
Sect. II. Commercial Gardens.

7453. Of commercial gardens, the lowest species are what are called ploughed or farmers' gardens. One or two are to be found near all large towns, and a number round London. They extend from fifty to a hundred and fifty acres or upwards, and are almost entirely cultivated by the plough and other agricultural implements. Their possessors are small farmers, and the chief difference between this farm-gardening, and common farming is, that the green crops that intervene between the corn crops are more highly cultivated, and instead of being consumed on the farm, are sent to market as culinary vegetables, or for stall-fed cows. The crops of every kind, but especially the green crops, are cultivated in drills, two close together, with a wide interval, by which means abundance of room is left to plough and horse-hoe the broad interval, and to sow a succeeding crop there before the other is removed. In this way two crops are obtained most years, as a specimen of which we shall mention one of the common rotations, viz. 1. Peas, with dung, two rows near each other, and a wide interval; 2. Turnips in the intervals; 3. Drilled wheat between the turnips; 4. Turnips, with dung, in drills after the wheat. These four crops are put in, and removed within two years, the ground being in good heart.

7454. The seed-garden is the next species, and forms one of the points of union between horticulture and agriculture. These gardens or small farms are not numerous, and confined chiefly to two or three counties near the metropolis. They consist of from five to twenty acres or upwards, in part cultivated by the plough; the occupier is not generally a bred gardener, but sometimes is so, and unites with the business of seed-grower that of market or nursery gardener. The seeds he cultivates are generally limited to a few kinds; thus chervil, radish, and cress seeds are grown chiefly in the neighborhood of Saffron-Walden in Essex; cabbage-seeds at Battersea; onions at Deptford; peas in Kent, turnips in Norfolk; rape in Lincolnshire; mustard in the county of Durham, &c. The great art is to grow the seeds true to their kind, for which purpose one grower must not attempt too many varieties of the same species, but he may grow a number of different species, and of varieties of the same species, provided they do not come into flower at the same time. Such seeds as are raised in large quantities, as turnip, mustard, cress, maw or poppy-seed, peas, &c. are either sold privately by samples, to the London or other seedsmen, or exposed publicly in the seed-market in Mark-lane, London, or in local country markets. But for the greater number of seeds, the practice is for the nurserymen about London to grow a sample of it in their own grounds as pure and perfect as possible, and then to send it to the seed-farmer to be sown and cultivated by him, and the seed ripened, cleaned, and sent to the nurserymen, at a fixed rate, by the cwt. or bushel. Flower-seeds are generally grown by nurserymen themselves; many of the other sorts by market-gardeners, and many kinds are received from the head gardeners of private gentlemen.

7455. Grass-orchards (Vergers agrestes, Fr.) form the next point of union between farming and gardening. There are a number of them in the cider counties, and in the Vale of Clyde, and Carse of Gowrie. A suitable soil and site are chosen, the surface, if not in pasture, is sown with grass-seed, and standard fruit-trees, chiefly apples and pears, and sometimes, as in Shropshire, plums and walnuts are planted in rows, and properly fenced. They receive little pruning, and generally receive no other care but that of gathering the fruit, which is either made into cider; stored in cellars; or sent immediately to market. As the trees get old and covered with moss or mistletoe, or infected with canker, shakes, or rottenness, they are scarified, headed down, and sometimes regrafted or rooted out and renewed, according to circumstances. (See The Orchardist, by Bucknald, and Hints to Proprietors of Orchards, by W. Salisbury.)

7456. Ploughed orchards differ in nothing from the grass-orchards but in being constantly or occasionally under oatation. The trees stand in quincunx, and every year the direction of the furrows is changed: thus, the first year it may be ploughed east and west; the second, south-east and north-west; the third, south and north; and the fourth, south-west and north-east. The stem of each tree is thus left in the centre of a square or rhomboid of turf of four feet on the side. The ground is cropped as in common farming, or farm-gardening.

7457. Market-gardens. (3758.) The number of these is considerable; their situation is near large towns or seaports, and their extent from one to fifty acres or upwards; some near London extend to upwards of a hundred acres. The object of all is to produce culinary vegetables and fruit for public sale, either as called for at the garden or garden-shop; as wanted by the green-grocer; or exposed in the public market. Some of these gardens are general, producing every description of culinary fruit and vegetable, hardy, exotic, and forced, in demand; of which, as examples, may be mentioned the Earls Court garden, of upwards of sixty acres, and with extensive hot-houses, by Gunter; the Hoxton garden, nearly equally extensive, by Grange; and the Isleworth gardens, by Wilmot and Keens. Other gardens near the metropolis are devoted chiefly to particular
crops; as that of Biggs, at Mortlake, to asparagus; some at Battersea, to cabbage and cauliflower; at the Neats-houses, to celery; at Deptford, to asparagus and onions; Charlton and Plumstead, to peas, &c. In some gardens attention is chiefly paid to forcing early, and growing late crops; in others, as at Lambeth, by Andrews, exotic fruits, as pines and grapes, are chiefly grown. At a greater distance from town, articles of easy carriage, as gooseberries, strawberries, asparagus, tart-rhubarb, sea-kale, &c. are leading articles; and in small gardens in the immediate vicinity of the metropolis, nothing is sent to market; but salads, as water-cress, radishes, lettuce, parsley, herbs, and flowers are the chief articles grown, and they are sold in small quantities on the spot. The market-gardeners near seaports direct their attention chiefly to the produce of cabbage, onions, turnips, and such vegetables as are in demand as ships' stores. In most parts of the country it happens, that from bankruptcies, absence of families, and such like causes, the produce of a number of private gardens is sent to market. This is a good deal the case near London; but so much so round Liverpool and Manchester, that scarcely a market-gardener is to be found near these towns. Indeed, many of the citizens there who possess villas and gardens, cultivate them as much for the sake of the disposal of the produce as for their own enjoyment.

7458. Market-gardeners on a small scale have generally been master or head gardeners, who have acquired a capital from a number of years' servitude; those occupying more extensive concerns are generally the sons or successors of other market-gardeners, and possess considerable capital. An important point in the culture of these gardens is to supply abundance of manure and water in dry weather; these always produce luxuriant and succulent crops of leaves, though obviously injurious in respect to flavor. A proper rotation and change of surface are also important; and in smaller crops it is a material point to have the rudiments of one crop always ready to succeed another. Thus radishes, lettuces, and onions are sown on asparagus-beds; the radishes are soon drawn, and succeeded by the lettuces and onions, which are left only in places where they will not injure the asparagus; the lettuces come into use soon after the asparagus is cut, part of the onions are drawn young, and the rest left to bulb. In the alleys between the beds, cauliflowers are planted early in the season, and between these, at a later period, cucumbers, which, with their runners, cover the vacant parts both of the alleys and beds. Thus six crops are obtained in succession, and the ground is clear by October for landing up the beds. Early cauliflowers are generally a profitable crop. The seeds are sown in August, pricked out, and planted under hand-glasses, six under each, in October. The glasses are placed in rows, ten feet apart, and at four feet distance from centre to centre in the row: thus an acre contains 1092 glasses. After the cauliflowers are planted, the ground is sown with lettuces and spinach; if the lettuce stands the winter, it is valuable, and grows fast when the soil is stirred round it in March. About this time, four of the six plants under each glass are removed, and planted in a warm situation, or in the sheltered alleys of the asparagus-beds. About the beginning of May the cauliflowers are too large for the glasses, and are just coming into flower. As they are gathered and their roots removed, they are replaced by cucumber-plants, previously raised in hot-beds, and now containing two or more proper leaves. In July the middle of the intervals between the rows of glasses is planted with endive, and between each glass two cauliflower-plants are planted to come in late. Thus five crops are raised, all valuable ones, if the ground was previously in good heart, and was kept frequently well stirred, and quite free from weeds. The following are common rotation: 1. Radishes, carrots, savoys or cabbages, or coleworts; 2. Early turnips, autumn cabbage; 3. Spring turnips, French beans, savoys, or peas and spinach, and leeks or broccoli.

7459. In saving broad-cast crops it is found of advantage to sow several sorts of seeds together, because some of them may fail or be destroyed by insects after they come up; if all come up and thrive, then such sorts that do best together. Thus onions and beets, lettuces and onions, are sown together; sometimes the carrots are sown, and the best crop is the onions; at other times the onions partially fail, and are drawn for salading or transplanting, and the lettuce is the main crop; Radishes are often sown with turnips, as a sacrifice to the fly, while the turnips escape. In general, all transplanted crops, and as many sown ones as possible, are drilled; and for bulky crops, as cabbages, peas, beans, &c. it is an approved practice to sow or plant two rows near to each other, and then leave a wide interval, in which a dwarf early crop, or crops of short duration, as spinach, lettuce, &c. is sown. By the time the main crop at its full size, the inter-crop is removed; the ground is then dry, and another crop, as cabbages or turnips, introduced, which is ready in its turn to succeed as the main crop. In this way, no part of a market-garden is ever left naked or cropless, at least during summer, and though these intervening crops are often injured when young by the shade of the main crops, yet, if the ground be in high order, they soon recover when freely exposed to the air, and the ground is stirred. If the land, however, is not in good heart, it is a better system to adopt a rotation, and stir the whole ground well between each crop, because here, the soil being poorer, a greater volume is required to supply the same nourishment; quantity is substituted for quality.

7460. The cultivation of the market-gardeners is, on the general average, nearly on a par; if one crop is at any time dearer than another, it is in consequence of being more precarious or expensive to raise; if one article is very dear at one time, it is immediately overgrown, and becomes proportionally cheap. To grow something of every thing is safe for those who have extensive concerns; select things for those who devote their whole attention to small spots; and things long of coming to perfection, as tart-rhubarb, sea-kale, asparagus, &c. to those who have capital. It is never advisable to propagate a dear article very extensively, as every body is likely to be doing the same thing; it is better even to adopt a contrary practice.
7462. A good deal of the profit of market-gardening depends on studying the state of the market; in gathering crops sparingly when things are low, and in sending liberal supplies at times, where, from weather or other causes, they are, or are likely to be high. This requires both judgment and capital, for the needy grower must sell at any price.

7463. Orchard-gardens. These are distinguished from the parterre or field orchards, in being cultivated with the spade, and cropped like a market-garden; indeed, they are so much allied to market-gardens, as hardly to require any separate discussion. In general, several kinds of fruit-trees are cultivated together, as tree-fruits, shrub-fruits, and herbaceous fruits; but some spots, from the soil, and probably superior culture, are noted for particular kinds of fruit, as Twickenham and Roslin, for strawberries; Maidstone, for filberts and cherries; Pershore for currants, &c. An account of the Isleworth mode of growing strawberries has been given in the Horticultural Transactions by Keens, an eminent grower of fruits and culinary vegetables. The filberts are planted in rows alternately with rows of cherry-trees; and, as temporary crops, a row of gooseberries, currants, or raspberries, are planted in each interval. Currants are grown extensively round Pershore, and the fruit sold to the manufacturers of British wines. They are also grown in Kent and Essex in rows eight feet asunder, and four feet from tree to tree. Early in spring the ground is dug, and sown with spinnage; to that succeed potatoes, and to those cabbages, which last are gathered as coleworts before winter: four crops, including the fruit, are obtained in one season.

7464. Herb and physic gardens. These are of limited number and extent, and generally occupied along with market or seed gardens. There are one or two for peppermint and a few other herbs, near Edinburgh, and the rest are in the vicinity of the metropolis, and chiefly at Mitcham in Surrey. Peppermint is a principal crop, which requires a moist soft soil, and to be taken up and replanted every three or four years. Lavender is grown to a considerable extent on lean soil, as is chamomile, wormwood, rosemary, thyme, &c. Licorice and rhubarb require a deep free soil; roses, which are grown in large quantities for their flowers, require a rich soil; white lilies and colchicum, grown for their bulbs, require a new soil. In one or two gardens near the metropolis, many species of herbs are grown to gratify the demand of certain classes of medical men, of self-doctors, and of quacks and irregular practitioners. Formerly there were many gardens of this sort; apothecaries generally grew a great part of their own herbs, and collected the rest in the fields; and hence the reason why so many of them formerly were eminent as botanists; but at present the only remarkable herb-garden is that of Messrs. Dicksons and Anderson at Croydon. These herbalists and seedsmen have constantly on sale, at their long established and respectable shop in Covent-garden, upwards of 500 species, including all the varieties mentioned by Culpepper and other herbalists of the 17th century. There are still one or two herb-shops which collect their simples in a wild state; but land is now so generally cultivated, that even if there were a demand for native herbs, this mode would not be very successful. It may be mentioned as a curious fact, that in Weston’s time, (say about 1750,) winter savory, chamomile, pennyroyal, peppermint, &c. were grown in the common fields near London, where cattle were turned out all the winter; the scent of these herbs being so disagreeable to these animals as to cause them to avoid them. (Weston's Tracts, &c. 71.) All herbs should be gathered dry, and in sunshine after dry weather; they should be dried in the shade, and when perfectly dried, pressed close by a press or weights, and enclosed in paper. The packets should then be deposited in a dry place, and when opened for use always carefully shut afterwards. The practice of hanging up herbs in loose bundles, tends to dry them too much and dissipate their flavor.

7465. Market flower-gardens. These are devoted to the culture of flowers for sale when in blossom; either cut as nosegays, or in pots. They are chiefly to be found in the neighborhood of the metropolis, where a sort of division of objects exists among them. Some gardens are noted for their roses; others, as that of D. Carter at Fulham, for growing the narcissus tribe; Colville in the King’s Road, for geraniums; Henderson at Paddington, for cheap heaths; the Bedford nursery for mignonette; and Smith, at Dalston, for forced flowers of all sorts. These gardens are not large; generally from one to a dozen of acres, and they are occupied by gardeners who have been brought up to this department of their profession. The standard articles of cultivation are roses, especially the moss-rose for nosegays; the monthly rose is also much grown in pots for spring and autumn sale. The sweetbriar is in demand for its odor; honeysuckles, lilacs, mezereons, rhododendrons, azaleas, spiraeas, double and scarlet-blossomed jasmines, laburnums, rose-acacias, are in great repute, especially when forced. All sorts of evergreens, as pines, firs, laurals, cypresses, arbor-vites, hollicies, yews, and above all, laurustinus and box, are much in demand for decorating balconies, flat roofs, areas, courts, lobbies, &c. Potted fruit-trees in bearing have generally a ready sale, and especially the grape and peach.
The common flowers for cut-grown are snowdrops, anemones, narcissi, hyacinths, ranunculus, tulips, liliums, auriculas, polyanthus, fuchsias, carnations, sweet peas, wallflowers, many other border-flowers, and most of the hardy plants.

The flowers prolonged in duration by being placed under glass before the speculative appearance, being in pots, and carefully kept, stocks of all the sorts, nasturtiums, veronicas, violets, gentians, monthly roses, laurustinus, fuchsias, dahlias, and chrysanths. The forest flowers are chiefly the pink tribe, violets, wallflowers, ten-week stocks, common stocks, hyacinths, crocuses, narcissi, tulips, tuberoses, fives, rose-campion, sweet peas, lupins, roses, lilacs, sweetbriars, roses, &c.

The scoring plants generally kept in pots are auriculas, polyanthus, pinks, carnations, Violets, fuchsias, veronicas, dahlias, chrysanthemums, phloxes, and saxifrages of sorts, most of the bulbs and many of the annuals and biennials. The flowers blooms in water-glasses are the hyacinth and narcissus chiefly, and also the crocus, tulip, amaryllis, colchicums, iris, &c.

7466. Of mignonette, perhaps more pots are sold in and near the metropolis than of any other potted plant whatever; fifty years ago it was hardly known. Next to mignonette may be named stocks, pinks, sweetpeas and wallflowers, among the hardy plants; hyacinths, among the bulbs; and geraniums and myrtles, among the exotics. Some years ago heaths and camellias were chiefly in repute; these being found difficult to keep in living-rooms, the public taste has changed, and the flower-grower varies his products accordingly. All these, and other sorts of plants in pots, are also lent out by the market-florist, to decorate private or public rooms on extraordinary occasions, but especially for those midnight assemblages called routs. This is the most lucrative part of the grower's business, who generally receives half the value of the plants lent out, as many receive them, and generally those of most value, are so injured by the heat as never to recover.

7467. Florists' gardens are devoted to the culture of florists' or select flowers for the sale of the plants and roots. There are not many exclusively devoted to this branch, excepting near Manchester and the metropolis. Those near Manchester, Paisley, and most other provincial towns are generally on a small scale, and cultivated by men who have auxiliary resources of livelihood; but near London are some extensive concerns of this sort, particularly those of Milliken and Curtis of Walworth; Davy of the King's Road; Mackie of Clapton, &c.; the first is celebrated for tulips and most bulbs; the second for pinks and carnation; the last for auriculas. This is one of the most delicate and difficult branches of gardening, and is only successfully pursued by such as devote their exclusive attention to it.

The great difficulty is to preserve fine varieties, and keep them from degenerating or sporting; many gardeners, excellent propagators and cultivators of hot-house and green-house plants, find it a very difficult task to grow a fine auricula or carnation; and their flowers would cut but a poor figure at the florists' shows, either near London or in the country. Much depends on the soil, which requires to be rich and well mellowed by time. It is also the most precarious branch of commercial gardening as a means of subsistence, since the purchasers are not so much the wealthy mercantile class who possess villas, or the independent country gentlemen, in whose gardens fine florists' flowers are seldom seen, as the tradesman and middling class.

The income of these being temporary, that is, depending in a great measure on personal exertion, and the current demand for their produce is, of course, easily affected by political changes, which make little difference to the man whose income arises from a fixed capital.

7468. Nursery-gardens. (1835.) In these are propagated and reared all sorts of trees and shrubs, and all other herbaceous plants in general demand; the culture of florists' flowers is often combined to a certain extent, and the dealing in seeds imported, bulbous roots, and garden-implements and machines, is generally considered a part of the business. Hence the designation of nurseryman, seedsman, and florist, formerly, and still, to a certain degree, common on their sign-boards. Of this class of commercial gardens, there is one or more in most counties of Britain, and a few in Ireland; but the greater number, and by far the most important, are in the vicinity of the metropolis. Their extent near town is limited; some contain only an acre or two, but others occupy forty or fifty acres; in the country where land is cheap, some are of double or treble that extent. In general they have been commenced by head gardeners, who had acquired a little capital, and continued by their sons or successors. In country nurseries, the commoner hardy fruit-trees, and tree and hedge plants, are the chief products: near Edinburgh and the metropolis some embrace every article of nursery produce, as the Hammersmith nursery, unrivalled in the world; others deal chiefly in fruit-trees, green-house plants, or American plants; and some almost limit themselves to particular species, as the camellia, erica, geranium, &c. The Scotch nurseries, and especially those of the northern districts, as that of Gibbs at Inverness, are famous for the raising of forest tree seedlings, which they sell in large quantities to all parts of the three kingdoms.

7469. The subject of nursery-culture embraces almost every part of gardening; since no department requires a more general knowledge, or so much attention and practical adroitness. The essential part of the business is the art of propagation; which, in some cases, as in multiplying heaths, and other Cape and Botany-bay plants, by cuttings, and in raising even the pine and fir tribes from seed, requires very delicate and accurate manipulation, and constant subsequent care and attention. Even grafting, budding, and layering, require to be carefully, skilfully, and expeditiously performed, and the future progress of the scion, bud, or shoot, carefully watched. Next to propagating, rearing requires attention, and especially transplanting and pruning; on the former depends the state of the roots, and of course the
fitness of the plant for removal; and on the latter, very often, the future figure of the tree. The Dutch and French nurseriesmen are in some respects superior traders to those of Britain: they generally re- move the fruit-trees from the nursery in June, and very few of them have fruit-trees for seven or ten years, training their heads at the same time in particular forms. The purchaser finds his heads already formed and bearing fruit, and with such tufts of fibrous roots that they require only a little private attention, either as herb, horn, or other, are trained in this way, and ready made hedges may be purchased by the foot or yard. (Hort. Trans. 201.)

7470. The most skilful and vigilant nurseryman can seldom make his practice conform to his knowledge. Thus, many customers, from ignorance, indolence, or unforeseen circumstances, defer ordering what they want, from the time of their sending for it till the last moment, which consequently prevents him from applying the requisite details of culture to his stock of plants and trees in the proper season. Thus the heading down of fruit-trees is often delayed, in deference to late purchasers, till the buds begin to push; and to cut them at that time, particularly vines, apricots, and cherries, would endanger their existence, and, at all events, if not ruinous, yet nearly so. In the case of other plants, it is necessary that the heads should be filled of the shoots to which they are to be made short, when they may be headed down not with much regard to shoots which have appeared, but more as they would have been cut in the proper season when nothing appeared but buds. The plant in a heavy soil should be cut when the sprout has grown down to some distance push, and regain in a great degree, the lost time; and, indeed, it may always be considered safe to rub off all shoots, not in desirable situations, from healthy trees, provided it be done early in the season. Trees which are not in full health, whether recently transplanted or not, should, in general, be left with their tops on; the leaves on which will prepare nourishment to strengthen their roots, and they can be too of preparing the following season. Some persons, after the drawing season, fill up the blanks in the lines of fruit-trees, with stocks to be budded the same year. This may do in new and excellent soils, and where there is little demand for fruit-trees; but, in general, the best way is to fill up all blanks that cannot be filled up with the tree kind in the proper season, with culinary vegetables, either for the kitchen or for seed, or with flowers to produce seed.

7471. The following are leading objects of nursery-management: —

7472. Correctness in the names given to plants and seeds of every description, and particularly to fruit-trees. To facilitate this, as to seeds and roots, their names should be painted on the various boxes, sacks, and chests in which they are kept; and as to fruit-trees, they should be designated by numbers painted on wooden, or cast iron, or stock-iron, and numbers painted, or even generally known, if possible, the whole of those planted along the borders, whether known or not, should have their systematic and English names painted on similar tallies; and smaller herbaceous plants in pots, and all exotics in pots, excepting such as come under the head of fruit-trees or plants, as vines, pines, &c. should be distinguished from them with a wooden label, if written on, or the number with Seton’s number-stick (fig. 161.) is by far the best for temporary numbers to fruit-trees, or for numbering own seeds or small plants. Some employ leaden, iron, or copper tallies, painted, but these are too conspicuous, and require too much labor in the preparation for a nursery. It appears to us, that, to prevent the confusion at the drawing season, one sорт, if not by accident or design, the following mode might be adopted: let a catalogue of fruit-trees be printed by the nurseryman, and let it contain against each name the number placed against the plant in the nursery; then every autumn before the drawing season commences, let a person with steel types of the numerals, and a marking-iron with the initial letters of their names, go through the gardens of fruit-trees, being at all things, put type 1. in a proper socket prepared in the marking-iron, and mark each tree fit to move, a few inches above the graft; let him next do the same with No. 2, having changed the type; and so on with the appositeness of names. The nurseryman should not sell the plants without the proper labels to plants sold, it would afford both to the nurseryman and the public who purchased his catalogue and his trees, a certain means of detecting error; as, should the label drop off in the hurry of carrying the trees to the packing-court, or in unpacking when arrived at their final destination, the number of the bark and the published catalogue could readily be referred to. If performed with a small sharp instrument, this practice could do no harm to the tree.

7473. Punctuality, accuracy, and despatch, in executing all orders.

7474. Rather procuring or omitting an article than sending off a bad one, unless under peculiar circumstances, is to be explained to the customer.

7475. Careful packing, and such as suits the sort of articles, the season, the distance, or the climate to which they are to be sent, mode of carriage, &c.

7476. Keeping an exact account of men’s time, and being particular in masting them every morning before commencing of depression, and again at the hours of rest and refreshment. This may be greatly facilitated by causing them all to enter and go out at the same gate, which ought to be that at the counting-house; and a bell or horn should call them to or from work.

7477. A vigilant eye to the truth while at work, and especially with strangers, till you are taught to them that you know what they can do by day or hour, by fair labor.

7478. Having one principal foreman or partner for the whole, and sub-foreman for the exotic, American, herbaceous, general nursery, and seed departments.

7479. Having a proper person employed as a traveller; or yourself or partner taking that department.

7480. Acting on all occasions with the utmost impartiality between gentlemen and their gardeners, leaning rather to the latter, in all doubtful cases, as the weaker party, according to the common consent and practice of all mankind.

7481. Paying all workmen, and, at all events your foremen, such wages for their labor as may not tempt them either to idleness or pifering themselves, or to countenance these practices in others.

7482. Publishing a printed catalogue on a scientific principle, of every article you have, or intend to have, and descriptive by its peculiarities; the description of the plant or fruit or plant in some generally known work; and placing, as above observed (7472), the same number opposite the names of your fruit-trees in the catalogue, as is actually placed against them on cast-iron tallies in the nursery, and annually in autumn, before the drawing season, impressed on all of them fit for sale as a marked-iron and a number.

7483. Attending at all times and seasons; and in every part of the nursery to frugality (avoiding meaning- ness and neatness, keeping every where a vigilant eye, and always being beforehand rather than behind, with the different operations of cultivation. Much may be done on the spot that cannot be done away from it, which may not be practicable, every operation as he goes along. Having taken up a tree or a plant, he ought never to forget to level up the hole; having pruned one, he ought at the same time to pick up the shoots, or if in a course of pruning, he should have a boy or man employed to do the same. When sent, they should be picked up all even and smooth, showing corresponding attention to order and neatness is requisite in every operation; and this attention once become a habit, will be found a saving of labor, and a source of profit as well as of pleasure.

7484. The management of the seed department is comparatively simple. The chief difficulty for seedmen who are beginners, and at a distance from the metropolis, is the ordering the proper quantities of each seed from the growers or wholesale dealers. The guides to this are the proportions of the different crops usually grown in private gardens, and the wants of the class who are likely to become purchasers. The same diffi-
culity occurs in beginning almost every business, and is only to be overcome by experience. The different periods to which different seeds retain their vegetative powers require to be known by seedsmen, as well as that they may not furnish lifeless seeds to their customers, as that they may not throw away as useless such as are possessed of the vital principle. Though few seeds are kept by respectable seedsmen above a year, yet in cases where a partial failure has taken place in the seed crop, most sorts will grow the second year after that in which they have ripened. Some, however, will keep from two to five or ten or more years; and others for an unknown length of time.

7455. The latest periods at which the seeds most generally in demand may be expected to grow freely are the following: —

Cabbage tribe. Four years.
Ligusticum culinarium vegetabile. One year.

Erected roots. Beet, ten years. Turnip, four years. Carrot, one year. Parsley, one year. Radish, two years. Sativa, two years. Skirret, four years. Scorzonera, two years.

Spinosus plants. Hyssopus, four years.
White beet, ten years.
Orache, one year. Parnallia, two years.

Patience, one year.

Alliuaceous plants. Two years.
Asparagus plants. Asparagus, four years. Sea-lade, three years.
Artichoke, three years. Cardoon, two years. Ram- piem, two years. Alianders, and the thistles, two years.
Asphodelus, in general two years. Lettuce, three years.
Endive, four years. Burnet, six years. Mustard, four years. Tarragon, four years. Sorrel, seven years. Celery, ten years.

Pol-herbs and garnishing plants, in general two years; but

7456. All seeds ought to be kept dry, and the air as much as possible excluded; but those liable to be attacked by insects, as the pea, bean, turnip, radish, &c. should be occasionally exposed to air and friction, by being passed through a winnowing machine. (fig. 283.) The more rare seeds should be kept in their pods till the season for using. Seeds received from foreign countries should, in general, be sown as soon as possible after their arrival. In packing seeds for the home demand, no particular process is requisite; but in sending seeds to America or the East Indies, the sorts which soon lose their vitality should be enveloped in clay, tallow, or wax, or put up in bottles rendered air and water tight. (281.)

7487. Bulbus roots, with the exception of the anemone and ranunculus, can only be kept out of ground a few months with propriety, though some are often found in the seed-shops as late as May. When thoroughly dry they may be kept in bags or boxes, and the more delicate sorts wrap up in papers separately. Ranunculus and anemone roots retain their vegetative powers two, and sometimes three years.

7488. The English seed-growers and seed-collectors furnish the greater part of culinary, flower, and indigenous tree-seeds sold in the shops, but a part also are obtained from other countries; as of onion-seed from Genoa; anise, basil, &c. from the south of France; carrot, onion, and a variety of seeds, when the English crop fails, from Holland. The harder bulbs, as crocus, daffodil, &c. are for the most part grown in England: the other hardy sorts are obtained from Guernsey, as the Guernsey lily; the Cape of Good Hope, as ixia, gladilios, &c. from South America, as the tuberose; or China, as the Japan lily, &c. The seeds of tender exotic trees and shrubs are obtained from the seed-collectors at the Cape, New Holland, and other foreign settlements; and of others from North America.

7489. The recommendation of head gardeners forms an important part of a nurseryman’s duty and care, and one in which he may render essential services to horticulture. He ought to select such as are well qualified for what they undertake, and consider himself as in some degree responsible for the conduct of the person recommended. In addition to this, the nurseryman, in the yearly tour he generally makes among his country customers to receive payments and take orders, should observe whether the person recommended has acted according to his expectations, and should exhort, reprove, or approve, accordingly. The nurseryman, while on this tour, by seeing a number of gardens and gardeners, must, by comparison, be well able to judge of their merits; and by judiciously dealing out approbation or blame, might do much good. The good gardener, who had become slovenly, from not seeing other gardens, or from the indifference of his employer, might thus be recalled to his duty, and the art not suffered to be disgraced by his practice. This is also the time for gentlemen to state to nurserymen the faults they have to find with their gardeners, so that they, by their advice, may endeavor to correct them. The nurseryman who has recommended a gardener, is the only person who can act as a mediator between this gardener and his employer; and we repeat, that by the judicious interference of well informed and experienced nurserymen, much good might be done; gardens kept in better order, and gardeners improved and retained, instead of being removed from their situations without being properly informed of their errors, and a proper opportunity afforded them of amendment.

Sect. III. Public Gardens.

7490. There are very few public gardens in Britain; and we can only refer to the enclosed areas of the public squares and parks of the metropolis and principal cities, to
the botanic gardens of the universities and other public bodies, and to the gardens of the two horticultural societies.

7491. The public squares are generally kept in order by jobbing gardeners at a certain rate by the year. The principal part of their business consists in keeping the grass short, by mowing once a fortnight in summer, and rather seldom in spring and autumn; in keeping the gravel clean, and keeping up a display of flowers in the dug groups.

7492. The public parks and other equestrian promenades are mostly managed by officers appointed by government; being once formed, and the trees grown up, they require little annual expense. The Mary-le-bonne or Regent's Park is in part let as a nursery-ground, and, instead of a rent, the occupier is bound to plant a certain number of trees the first year of his lease, to nurse up these, and leave a certain number of them on each acre at the end of his lease. A considerable part of this park is also, as already mentioned, let to private persons for the purpose of erecting villas, which, though it will control the rambles of the pedestrian, will give and maintain a wooly appearance, without any expense to the public.

7493. The botanic gardens of the universities are under the general direction of the professor of botany, and managed by a head gardener or curator: those, founded by subscribers, or a society, as the gardens of Liverpool, Hull, Glasgow, and Dublin, are under the direction of a committee, and similarly managed. The duties common to curators are the keeping up and increasing the collection of plants; those who manage university-gardens, have, in addition, to furnish specimens of certain plants in sufficient numbers for the use of the professor and students. In some cases, the curator is required to instruct students; and in others, he is permitted to do this, and to take pupils or apprentices for his own emolument. Most gardens exchange, and some, as that of Liverpool, sell plants and seeds.

7494. On the cultivation of botanic gardens we shall offer only a few general hints. Instead of the principles of substitution and a resemblance of natural order we use, the soil, On large or small plots, it is to be effected by removal of the whole, or a proportion of the old soil, and the introduction, and thorough mixture of a proportionate quantity of good virgin loam, or of virgin peat, bog, or sand, according to the plot or border to be renewed. In rock-wrorks, and beds, American grounds, and in most of what may be called particular habitats, there is no other way; but in the plots which contain the general arrangements, deep trenching may partially or wholly supply its place.

7495. Manure cannot altogether be dispensed with in botanic gardens, particularly for some or most of the new plants. The manure will be included under the culinary, agricultural, and flower-garden departments; but, in general, decayed leaves is the best manure for all other plants and trees, not in a state of monotony or otherwise changed by cultivation.

7496. Sheltering and shading are parts of culture which demand very considerable attention in botanic gardens, especially in warm climates. Delicate plants which require a moist atmosphere, as some alpines and Americans, require to be closely covered with a hand-glass, and this again partially with a wicker case during the whole summer, even if under the shade of a wall or hedge.

7497. In sowing, and causing to vegetate, seeds which have been brought from a distance, a good deal of skill is often requisite. Sowing in very fine earth in pots, covering them with a bell, and placing them in the shade and in moist heat, is the most likely mode to succeed, whatever climate the seeds may have been sent from. To this, some add previous steeping of the seed in pure water, and in water impregnated with the acid or alkali of the soil, or in water with which the soil may be impregnated, and some charge the earth of the pot with the gas, and others invert a bell-glass over it, containing an atmosphere partly or wholly composed of the gas. (See Hill, in Hort. Trans. vol. i. 583.) All these modes, and by vegetable chemistry, perhaps, may be tried, but generally the best method is to sow the first mode will generally be found sufficient. Numerous annual and biennial seeds require to be sown every year, independently of seeds of new sorts from foreign countries. For collections of these in beds or in a general arrangement, the mode of sowing in rows across the bed, is obviously the best; and several rows radiating from a polygonal tail in the centre, is the most economical, as admitting of the greatest number of sorts in the least space.

7498. With respect to management, there are various duties belonging to the office of curator of a public botanic garden which are peculiar to the situation; some of which we shall briefly enumerate.

7499. Gathering and drying specimens to maintain the herbarium, and to exchange or give away; frequently inspecting the herbarium to guard against damp and moths; collecting and preserving seeds of every kind for the purposes of exchange.

7500. Collecting wild plants, and seeking for new species in proper situations; in uncultivated haunts for them, in haunts impugned by birds, for trees; in bays, and sheltered creeks, and shores, for aquatics; in rocky shores for marine plants; among the tops of snow-clad mountains in winter, for mosses; in old forests in winter for lichens, and in spring for fungi, and so on.

7501. Acclimating plants, by raising them from seeds, one generation after another, till the final progeny will endure the open air throughout the year. Dr. Walker (Essays) states how the passiflora caerulea was acclimated in Scotland, merely by time, without propagation from seed. Sir Joseph Banks (Hort. Trans. vol. i. 21.), by sowing the seeds of succeeding generations of the zianias aquatica from 1791 to 1804, “and transplanting the annual plant seasonably to endure the winter with vigour, and under the haunts of the various genera, as strong and as vigorous as our indigenous plants are, and as perfect in all its parts as in our native climate.” Next to the ordinary duties of a botanic curator, this appears to us much the most important he has to undergo the horticulture and agriculture of his country, to render it as common and as easily reproducible: being supported by the public, it ought to have been devoted to its service.
7503. Giving the name and history of plants to all eager enquirers, in order to encourage a desire of botanical knowledge, is indispensable to the welfare of the great body of botanists and my vegetable kingdom, by pointing out striking peculiarities of plants to superstitious observers, in order to attract their attention; trying to point out things which may assimilate with the taste or foible of the person addressed; recollecting that sexual matters and matters bordering on the marvelous, are the most generally attractive to volatile or vacant minds; in this way becoming all things to all men, in order, by all means, to gain some.  

7504. Discriminating and dispersing seeds and plants of scarce natives, or of foreign sorts not yet naturalised, by placing them in their proper soils and habitats. Thus, when the aquatic plants are reduced, the first plants men from rare ones, into an adjoining ditch, lake, or rivulet or rivulet or rivulet; and the plant the seeds of plants in sandy soils or shores, and so on. Curator Anderson of the Chelsea garden scatters all his spare seeds on Battersea, Clapham, and Wandsworth commons, and throws his spare aquatics into the Thames. The consequence is, that though only a few years since, some rather scarce things have been distributed in these places. Dickson, an enthusiastic botanist, naturalised that beautiful plant, the fresh-water soldier, in the ponds about Croydon; as they have been done the same plant, and several others, in the Serpentine canal in Hyde Park. Salisbury, one of the first botanists of the age, and equally eminent as a horticulturist, thinking he could naturalise on our sandy shores the panameria of various kinds; and the naturalised corniculatum, and eryngium maritimum, with which he saw it growing wild below Montpelier (Hort. Trans. vol. I. 341); and when at school, in the neighborhood of Halifax, in 1785, he was flogged in the Whitladies; holidays, for helping to propagate the narcissus triandrus, and for running out of bounds to know the name of it at North Bierly.

7505. A catalogue of every botanic garden should be printed for exchange, distribution, or sale. Very complete gardens, such as those of Kew, Cambridge, and Liverpool, find it answer to publish printed catalogues, with a view to remuneration by sale; but the legitimate object of a botanic-garden catalogue is, to exchange it with that of other botanic gardens, foreign and domestic; in order, that by comparison of riches, exchange may be made for mutual advantage. For this purpose, it seems desirable, that every thriving establishment should print or prepare a catalogue once a-year, or once every two or three years. To facilitate this, it might be printed by the lithographic process, from a list written in a small hand on prepared paper. By printing only the botanic names, each sheet would contain nearly four thousand names, and consequently three sheets, all the plants, native or introduced into Britain. This might be produced stitched together, all expenses included, for a trifle; and as the present law respecting letters stands, might be franked in separate sheets. Thus a cheap communication between British botanic gardens might be formed, and through our foreign ambassadors, these catalogues might be distributed all over the world.

7506. A catalogue may be formed of figures, where it is not convenient to form one of printed names. Thus the possessed or desired plants might be indicated by putting down the numbers placed against the names of the plants in some generally circulated botanical catalogue. If, in the excellent catalogue of Sweet, the genera had been numbered as in the synopsis of Persoon, it would have been the best; in the mean time, Persoon's work, as it is in the hands of most botanists, foreign and domestic, may be referred to; and as an example of the brevity of this kind of catalogue or reference, let us suppose one curator wishes to write to another to Varonia crenata, lineata, bullata, and globosa; all he has to do is to write for Pers. (Persoon), 371. (the number of the genus), and 1. to 4. (the numbers of the species desired), and similarly as to all the plants described in Persoon's Synopsis. Ten thousand plants would in this way be represented by about 11,500 figures, which might occupy one sheet of letter-paper. But our Encyclopaedia of Plants, and catalogue entitled Hortus Britannicus, are numbered in such a way as to render communication more facile than any mode of using Persoon, or any other species plantarum or catalogue whatever.

7507. The gardens of the horticultural societies, being at present in a state of embryo, do not admit of description. The published plan of that of the London Society (Report on the Formation of a Garden, &c. 1823), appears to us most defective in general arrangement. It is in part executed; and if completed according to that plan, there will be, as we think, a want of grandeur and unity of effect as a whole, and of connection and convenience in the parts. One obvious error that must strike every one that has had no part in making it, is, the forming the arboretum in a large rectilinear clump; and another is scattering the hot-houses and other buildings here and there over the garden. There should, in our opinion, have been three grand parts: a centre for all the buildings of every description, with the exception of entrance-lodges and resting-seats, or shelters, &c.; a circumference, displaying the arboretum, fruticetum, and ornamental flowers; and the intermediate space laid out as culinary, desert, floricultural, experimental, naturalisation, and nursery gardens. The hot-houses requisite for these different departments might easily have been arranged so as to be included in each of them, and yet forming with the other buildings a whole or connected chain round the central area, and these might have been all heated from the same steam apparatus, and the sheds and other parts and buildings lighted, if desired, by gas. The grand entrance should have presented three carriage-roads: one to the centre, to which visitors could drive and inspect the hot-houses of all the departments, and just take a coup d'ceil of the open gardens belonging to them; the two others proceeding to the right and left, and forming a circumferential one, along which visitors might drive round the whole arboretum or shrubbery, and enter if they chose by six or eight communications, at different distances, the six or
eight different open gardens. This is but a first rough sketch of what might have been, but such as it is we leave it as our protest against the present plan, from the details of which the reader will judge for himself.

7508. The London Horticultural Society’s garden contains 33 acres, of which 17¾ are devoted to horticulture (A), 13½ to floriculture and arboriculture (B), and 1¾ to lodges, roads, yards, &c. (C).

7509. The garden of the Caledonian Horticultural Society is not yet in a state to be discussed.

---

**CHAP. III.**

Topographical Survey of the British Isles, in respect to Gardening.

7510. The British isles are naturally and politically more favorable to the practice of horticulture in all its branches than any other country; in no country is so great a proportion of the surface covered with gardens, including, under this term, the parks or landscape-gardens, which surround gentlemen’s seats. The beauty and magnificence of these parks, and the villas, mansions, castles, and palaces, of which they are the appendages, far surpass what is to be met with in any other part of the world. The palaces and scenery of Italy are more interesting to artists and classical antiquaries, from the particular associations necessarily connected with their pursuits; but the views of an accomplished and well regulated mind will extend to other kinds of excellence, as well as those of picturesque or classic beauty; and a man that knows to what extent civilisation and refinement are carried in different parts of the world, will look into the interior of these casinos and palaces, their gardens and farms, and enquire to what extent they would contribute, in their propriety, salubrity, furniture, produce, and management, to the gratification of the wants of an Englishman in his present state of refinement. In these particulars he will find them so very deficient, as to admit of no sort of comparison with those of Britain.
7511. Of the state of gardening in each of the different counties of the United Kingdom, the following notices are necessarily imperfect to a certain extent; from defective information some things are omitted, and erroneous statements may exist as to others. In the selection of the names of the principal country-residences, some are undoubtedly admitted which may not have that claim, in comparison to others which are excluded; and others, though they once had that claim, may now have it no longer, from neglect, change of ownership, or even destruction as a country-seat. Most of the descriptive hints, added after the names of country-residences, refer to the state they were in some years ago, some as far back as 1805; and the changes in the names of the possessors that may have taken place since that time must no doubt be the cause of various errors, though we have spared no pains to avoid them. The descriptive epithepts, added to the names of places in the southern kingdom, are taken generally from the Beauties of England and Wales (London, 26 vols. 8vo. published from 1801 to 1815); those of Scotland from the beauties of that country (5 vols. 8vo. Edin. published from 1802 to 1809); and those of Ireland from The Traveller's Guide (1 vol. 8vo. Dublin, 1819), and from the information of a correspondent there, well acquainted with every part of that country. We have visited all the counties of Britain ourselves in 1804, 5, and 6, and since been professionally engaged in several of them; and we have also made a general tour of Ireland in 1811. When any remarks occur which are not found in the books referred to, they may, for the most part, be considered as the result of our own observation at these periods or since. From the limited space that we can devote to this part of the work, these remarks are necessarily very few; we have omitted stating any thing as to the indigenous plants; and said very little as to the natural woods or artificial plantations of each county. All the seats which are of established celebrity, and are, or were, what are called show-places, are distinguished by a cross (\times) of most of these places accounts have been published in the local guides, sold in country-towns.

7512. The surface of England is estimated at 32,150,000 acres, almost everywhere cultivated, and nowhere incapable of cultivation; in most places varied — gently and beautifully in some districts, and abruptly and on a grander scale in others. The most hilly and mountainous districts are those of the north, and the most level those of the east. The most humid climates are those of the western and northern counties, as Lancashire and Cheshire; and the most dry those of the east and south, as Norfolk and Sussex. The richest soils, and those in which gardening, as an art of culture, and as a trade, has been carried to the greatest perfection, are those round the metropolis; there, within the circuit of ten miles, it is estimated (Lyson's Environs of London, published 1792 to 1796), 500 acres are employed in raising culinary vegetables; 800 acres covered with fruit-trees and shrubs; 300 acres in medicinal herbs; 500 as nursery and florists' gardens; besides not fewer than 1200 acres employed by farming gardeners in growing potatoes for the market; and 1200 occupied with turnips, cabbages, parsnips, and white beets for milk-cows. Gardening, as an art of design and taste, may be considered as nearly equally advanced in almost all the counties. Some of the most highly kept gardens and country-residences are in Middlesex and Surrey; of the most extensive and magnificent in Oxfordshire, Yorkshire, Nottinghamshire, and Devonshire. The best examples of cottagers' and farmers' gardens are in Essex, Kent, Norfolk, and Lancashire; the seed-gardens are chiefly in Essex and Kent; orchards in Herefordshire, Warwickshire, and Devonshire; and market-gardens and nurseries are distributed according to the extent and population of the different counties. These counties are forty in number, and we shall take them in the order of the circuits made by the judges, being that in which their names are most generally associated in our memories, and that also in which they are not unaptly classed in regard to beauty and character.

7513. MIDDLESEX, occupies the north side of a vale watered by the Thames, and containing 179,800 acres, of which one part is clayey and another marshy, but the greater part productive. As containing the metropolis, it may be considered the richest county in the United Kingdom as to culinary and flower gardening. The depot or market, where chiefly these productions are exposed for sale, is Covent-garden, an open square, laid out with fixed temporary wooden shops and stalls. The vegetables and commoner fruits and flowers are brought in by carts and wagons three days in the week, Tuesday, Thursday, and Saturday, so as to arrive in the market between three and five o'clock; they are then sold by regular salesmen to the retailers of the market, or to green grocers, fruitriers, and stall-keepers from different parts of the town. In general the terms are adjusted, and the market cleared of the vehicles and horses by ten o'clock or earlier in the summer, no more remaining in the market than what is found by the different owners to be sufficient for the local consumption. The more valuable fruits and flowers, such as forced strawberies, peaches, grapes, and pines, and forced roses, hyacinths, and nosegays, during winter, are generally sold by private contract to the fruit-shops in the market, or to others distributed in different parts of the town. The principal fruit-shop is that of Grunge, in Piccadilly, who is the king's fruiterer; the principal flower-shop that of Smith, in Covent-garden market. Besides the central market of Covent-garden, there are others in different parts of the town, as the Fleet, Newgate, Borough, &c. which receive very considerable supplies of the leading kinds of vegetables direct from the country; but the forced productions, and the more expensive fruits, are generally brought to Covent-garden, when not disposed of to the shops by private contract.
GARDENS OF MIDDLESEX

751. The seed-market is held twice a-week, on Mondays and Fridays, in a large roofed space in Mark-lane. Here the growers or holders of garden-seeds, and of such agricultural seeds, as are commonly sold by nursemen, as clover, rye-grass, &c. attend and transact business by sale. The purchasers are mostly London retailers, or the wholesale dealers for their country customers; nothing is there sold by retail.

756. The produce of the nursery-gardens is sold on the spot; as is also that of the florists' gardens; the herb-growers sell their productions to the wholesale druggists and manufacturing chemists by sample.

757. The public gardens of Middlesex are as under:

- Greenwich Hospital
- The gardens of the principal royal palaces and parks, the royal parks and gardens are the parks of St. James, the Hyde, and Mary-le-bone.

The principal public gardens of Middlesex are those of Chelsea, containing between three and four acres. The oldest and most celebrated of these is the Chelsea Physic Garden; the first notice of it in the book of the Apothecaries' Society is in 1774, when it was proposed to wall it round; and two years after, 1776, it was finally completed in the hands of Mr. G. G. Salmon. However, it is now used as a botanic garden, and its name is the name of the first curator, noticed in 1776. Watts, mentioned, both by Bay and Evelyn, was an apothecary by profession, but undertook the care of the garden in 1650; at 50 per acre, Miller was appointed in 1723, at the time Sir Hans Sloane, when applied for a renewal of the lease of the garden, granted it to the Society in perpetuity at a rent of $5. per annum. The production of this garden was originally intended to be used for the medical purposes of the Society, but now it is used for exotics, and is well known for its rare and choice plants.

- The two green-houses at Chelsea, which have been extensively employed for a century, were built for Lord Mansfield, as a place of residence, and are named after his wife. They are named after the name of the first curator, noticed in 1776. Watts, mentioned, both by Bay and Evelyn, was an apothecary by profession, but undertook the care of the garden in 1650; at 50 per acre, Miller was appointed in 1723, at the time Sir Hans Sloane, when applied for a renewal of the lease of the garden, granted it to the Society in perpetuity at a rent of $5. per annum. The production of this garden was originally intended to be used for the medical purposes of the Society, but now it is used for exotics, and is well known for its rare and choice plants.

- The garden of the Chelsea Physic Garden is extensive, containing about two acres of land. The garden is divided into three parts; the first is the physic garden, the second is the flower garden, and the third is the fruit garden. The physic garden is used for the cultivation of herbs and medicinal plants, while the flower garden is used for the cultivation of flowers and ornamental plants. The fruit garden is used for the cultivation of fruits and vegetables.

- Kew Gardens was established in 1731 by Sir Hans Sloane, who was a doctor and a botanist. He donated his collection of plants to the nation, and in 1731, the garden was opened to the public. The garden is now known as the Royal Botanic Gardens, Kew, and is a major attraction in London.

- The garden at Kew is extensive, containing about two acres of land. The garden is divided into three parts; the first is the physic garden, the second is the flower garden, and the third is the fruit garden. The physic garden is used for the cultivation of herbs and medicinal plants, while the flower garden is used for the cultivation of flowers and ornamental plants. The fruit garden is used for the cultivation of fruits and vegetables.

The physic garden is used for the cultivation of herbs and medicinal plants, while the flower garden is used for the cultivation of flowers and ornamental plants. The fruit garden is used for the cultivation of fruits and vegetables.
The Bulstrode Nursery,—Messrs. Brooks and Co., has been established upwards of half a century, and is carried on with much spirit, collectors being sent out to distant countries, and many new plants imported. Among these are several curious herbs, and the garden is managed by Mr. R. Hunter, who is at present kept up in a very respectable state.

The Mill-end Nursery—was established by James Gordon, gardener to Dr. Sherrard, at Eltham, and passed successively to Gordon, Derrmor, Thompson and Co. (Gordon, Forsyth, and Co., and Thompson and Co., by whom it is at present kept up in a very respectable state.

The Mary-le-bone Nursery,—Thomas Jenkins, has been established within the present century; it is of considerable extent; contains extensive hot-houses for forcing flowers, for greenhouse plants, and pits for pine-apples. It also contains a subscription botanical garden.

The Cottage-gardens of Laboureur,—near town, are not remarkable for management, but in the western and eastern extremities of the country they are very well kept. The Cottage-gardens of Artificers—are often very neatly kept; producing, besides fruit, flowers and vegetables, other operations who have a taste for flowers.

Farmers’ Gardens.—As many of the farmers near the metropolis are retired or speculative London tradesmen, they have often very neat gardens. Those to the west of London may be referred to in examples.

Suburban and Citizens’ Villas—are in considerable number, of various degrees of extent; but generally neatly kept.

7520. Villas are numerous in every part of the country; a few may be enumerated:

Arno’s Vale,—near Southgate: J. Walker, Esq. A noble mansion, chiefly by Sir R. Taylor: the grounds comprise woods watered by the New River; the flower-garden is rich, and there is an extensive range of hot-houses containing an abundant collection of exotics.

Cullum’s Grove,—near Southgate: Sir W. Corvis. A substantial villa, and good kitchen-gardens, with hot-houses, on which no expense is spared.

Canons,—near Edgware: Sir Thomas Plumer. A dull flat of rich pasture, intersected by rows of elms, and surrounded by a brick wall.

This place is remarkable as having been the site of the improvements of the celebrated Duke of Chandos, who rose from the rank of a private gentleman. James Bridges, Esq., married into the family of Lake, then proprietors of Canons. Having made his fortune as a paymaster in the German war, and acquired his title, he built the magnificent mansion of Canons about 1712. It stood nearly in the centre of the park, at the end of a spacious avenue, being placed diagonally so as to show two sides of the building, which, at a distance, gave the appearance of a front of a prodigious extent. Vertue describes it as a “noble square pile, all of stone; the four sides almost alike, with statues on the front; within was a small square of brick, not handsome, the offices of brick and stone, very convenient and well disposed,” &c. The architect was James, of Greenwich, and the whole expense of the building and furniture is said to have amounted to 200,000L. Dr. Alexander Blackwell, author of a treatise on agriculture, who afterwards went to Sweden, where he died, and whose widow published a work on the same subject, was employed to superintend the works out of doors. Lysons thinks it is probable he laid out the pleasure-grounds; but it is not unlikely that the architect, James, of Greenwich, and the whole expense of the building and furniture is said to have amounted to 200,000L. Lysons thinks it is probable he laid out the pleasure-grounds; but it is not unlikely that the architect, James, of Greenwich, and the whole expense of the building and furniture is said to have amounted to 200,000L. The grounds are now disposed in good taste.

Ealing Grove,—near Ealing: C. Wyatt, Esq. A substantial and commodious house, and forty acres of ground arranged with much judgment.

Earl’s House,—at Earl’s Court: John Baynes, Esq. Was the villa for the late celebrated surgeon, John Hunter. Here he had a curious menagerie.

Flambards,—near Harrow: Lord Northwick. The house being in the village, from its elevation commands astonishing fine views; the grounds are disposed in good taste.

Fordham,—near Ealing: Charles Duval, Esq. A good house, once the residence of Fielding; the grounds economically and tastefully disposed.

Forty Hall,—near Enfield: J. Meyers, Esq. The house originally by Jones, but altered; the grounds extensive, unothing, bounding in lefty elm and ash-trees, and adorned with several curious edifices.

The Grove,—near Stannmore: C. Poole, Esq. The grounds are remarkable for containing an island and tomb, in imitation of the Isle des Poyntiers, at Ermenonville, and of Rousillon’s tomb, formerly there, but now in the possession of Paris.

Grosvenor’s Park,—near Ealing: C. Copesland, Esq. A desirable villa, with seventy acres of ground, adorned by two
Gardens

for principally red, the willow, generally been of the Countess of Suffok. They contain much venerable

Marble Hill — near Twickenham; C. A. Fulk, Esq. The grounds have been largely laid down, and are open to the public for the improvement of Rhododendron, and other American plants; there is a fine terrace with a view of the most elevated part of the town, and a magnificent collection of hot-houses 300 feet in length, and a group of aviaries for hollyhocks, poppies, and other kinds of plants.

Stunmore House, — near Stummore; G. H. Drummond, Esq. The house and grounds originally by Holland; the grounds, since improved by the present owner, contain many species of hardy and tender shrubs, and large limited extent.

Tudor House, — near Etonfo; J. Cumming, Esq. A spacious brick structure on a fine swell in the midst of a park of 300 acres, more varied by irregularities, and of a bolder character than any in the country.

Westham Place, — near South Mims; G. Byng, Esq. A spacious residence at this command, the commanding eminence: the park is rather deficient in wood.

Gardens of this county are chiefly in London, but there are a few in the country.

X Holland House, — near Kensington; Lord Holland, magnificent Elizabethan mansion, with a demesne of 300 acres, of which there is a splendid collection of trees, and a flower-garden, beautifully laid out and managed. Here the ruins of the old house still exist; but the present magnificent mansion built by Sir John Soane in 1764, has been architected with masonry, ornaments, and resemble a rude product and the wood. The grounds between the dacha was first successfully cultivated in England.

X Shn House, — near Brentford; Duke of Northumberland. Once the residence of the Duke of Brakelton. The grounds were formed by Dr. Turner, author of The Herbal, a botanic garden formerly possessed by the house, a magnificent quadrangular structure of stone, improved by Adams, and more recently by Hardwick and Wren, now possesses a fine collection of trees and the pleasure-gunds with many venerable cedars, and other exotic. They were laid out by Brown; lately under the care of Mr. Adams, and now of Scrope, author of An Introduction to Botany.

Royal Gardens. Of these there are four. Carlton Gardens, Hampton Court, Kensington, and St. James's.

Carlton Palace Gardens — were originally laid out by Kent, for Lord Carlton; and afterwards by Brown and Holland, for the present residence of the Prince of Wales. They are not much enriched with flowers and shrubs, or in high keeping. A detached structure, a conservatory, a copy of a skeleton of Henry VIII's chapel in Westminster Abbey: but though handsome as a piece of architecture, it is of little use as a plant-habitation, being in fact intended more as a lounge and resource for an extra room on great occasions.

X Holland House, built in the Elizabethan style, and perhaps the most magnificent, of all the royal palaces: principally built by Sir Richard Eden, and Henry VIII, and most recently by Sir William Chambers, and is in the style impure Grecian. Its situation is upon the north bank of the Thames: it is entered by forty-four acres laid out in the Dutch and Italian taste, and for the manner of the grounds and Wise. The ground belonging to its park, is of considerable extent. The grounds consist of Buxy Old Park, New Park, Middle, Rye Warren, and Hampton Court. The gardens contain a labyrinth, one of the most perfect, as to preservation, in England: the privy garden is ornamented with terrace-walks, and near it is a graceful arbour, formed in the style of the age.

X Kensington. — The park of a large brick building, by its size, it is the park which is the most celebrated, more than the greater part of their surface. The gardens are three miles and a half in circumference, and are chiefly composed of gravel, and shaded walks, with a circular basin and river. The finest point of view is from an entrance on the Westbridge Road. The house is adorned with many fine statues, and the effects of the late W. Forsyth, mode of managing fruit-trees; at the English House, near Llanes. The gardens consist of its hot-houses, in which the pines are better cultivated than in any other of the same kind in England. The grounds was only thirty-six acres. Queen Anne added thirty acres, which were laid out by her gardener, Wise. Queen Caroline laid them out, with much more taste, in the English style, laid out by Bridgeman. Being royal gardens, several poems have been written on them, from the time of King William to his works; another in 1729; and a third in the pastoral calendar in 1759.
adapted for villas and other residences. That part of the metropolis which is within the county, contains a garden-market for the commoner fruits and vegetables, but it is not extensive. There are several respectable seed-shops, and the greatest seed-factors reside here in the suburbs and suburban villages, are some good market-gardens, the principal herb-gardens in the kingdom, and some seed-gardens: juniper-berries and cranberries used to be gathered on the commons on Box Hill and Leith Hill, and sold in the metropolis. There are a few nurseries: the county abounds in villas, and contains some mansion-residences. There are no public gardens in the county; but the private gardens of Greenwich Park, in Kent, adjoins the metropolis. In Stevenson's survey of the county, it is stated, that 3500 acres are employed as farmers' market-gardens. The greatest gardening author this county has produced is Evolve, of Wootton, House, and the most celebrated gardens which have existed in this country those of the Carews, at Beddington.

7525. There are various commercial gardens. Farmers' gardens. — Of these there are a considerable number in the low part of the county, adjoining the Thames. Turnips are grown in abundance and in great perfection, for the cow- feeders.

Market-Gardens. — There are some highly cultivated and of very considerable extent on the banks of the Thames, especially at Barnes, Mortlake, and Camberwell. The two former places are famous for asparagus, and Battersea for cabbages. There are generally about eighty acres under asparagus in the parish of Mortlake: the greatest grower is Hee, who has had forty acres under this crop at one time. There are some good gardens near Chertsey, and here the Chertsey or green Surrey carrots is better grown than anywhere else, and the London seedsmen are supplied from the growers with its seeds. The hardy fruits are less generally grown for the markets in Surrey than in Middlesex and Kent; but there is one celebrated grower of exotic and forced fruits, Lasce Andrews at Lambeth, famous for his pine-apples, and being annually among the first who send early grapes and cherries to market. His hot-houses, like those of Gunter and Orange in Middlesex, are also heated by steam.

Herb and Physic Gardens. — These are chiefly in the parish of Mitcham, where the soil is poor and gravelly. The oldest establishment of this description is that of Potter and Moore, who formerly grew most of the articles in the vegetable materia medica as then in use. They now grow chiefly roses, lavender, chamomile, the mints, opium-poppy (Papaver somniferum), balm, blessed-thistle, borage, clary, hyssop, sage, scarlet-grass, angelica, thyme, fennel, pot-marigold, &c.

Middlesex. — In Middlesex, Benjamin Moore, at Trimley, near Woodford, has a gardens at Croxden for a general collection of such herbs as are only in demand in small quantities.

Market-Flower-Gardens. — There are several of these near the metropolis, but none eminently deserving description.

Florists' Gardens. — The principal of these is that of Meers, Milliken and Curtis, at Walworth, who have the first collection of bulbous flowers in this country. It was founded by the late — Maddock, author of the Florist Directory, about the middle of the last century. There are also one or two other very respectable gardens of this description.

7527. Villas. We have selected a few; but the number that merit attention is more than double those here named.

Mousehills, near Crowdon; Archbishop of Canterbury. A good house is the centre of a park, much varied and well planted: the house lately enlarged and improved.

7541. Millroy PLACE. — Near Blackheath; S. Thornton, Esq. An elegant Ionic mansion; greatly altered and improved by the present proprietor. The park, a beautiful piece of ground, of 900 acres, finely wooded, especially with old Spanish chestnuts. Thousand Pines planted in the park, and a lawn and fountain in the garden. This place was noted in Evelyn's time (p. 518) for the subterraneous passage of 100 yards in length.
made nearly through a hill, but a rock at the south end prevented the design from being completed.

Gardens, near Witley. An elegant stone mansion, in a park well stocked with timber, and adorned with a fine piece of artificial water, with a bridge at one end of it.

Burrwood Park, near Walton; Sir J. Frederick. An elegant stone mansion, with a park of 300 acres, intersected by a single footpath, to the rear of bay window.

Forest Hill, J. M. Ewart, Esq. Worthy of notice on account of the kitchen garden, which is surrounded by a road, the area enclosed being that on which the former mansion stood. The present house is much inferior in style and quality with any of the other buildings here described.

Deerpark, near Dorking; T. Hope, Esq. A man of great wealth and taste, and who has been very active in the improvement of public matters. The pleasure-ground is circular in form, and the approach is by a flight of stairs. The beech avenue is over 500 feet long, and the periphery of the circular pleasure-ground is 1,000 feet. The ground is covered with grass and the park is excellently managed.

Shrub Hill, near Dorking; Lord Leslie. A commodious and pleasant villa.

Streatfield, near Streatham; A. Atkins, Esq. The grounds contain 100 acres, surrounded by a shrubbery and gravel walks. The house is a large and handsome one, and the garden is made an object of considerable interest, as the garden is very well planned and contains many fine trees and shrubs.

St Ann's Hill, near Clayworth; Mrs. Fox. The gardens and pleasure-grounds of moderate extent, but laid out with much taste and care. The house is a very fine one, and the gardens are moderately attractive and enclosed with a wall fourteen feet high.

1798. The mansions with demeces, in Surrey, are few compared with the number of villas.

Ashbol Park, near Ryegate; Hon. F. G. Howard. An elegant mansion, with magnificent stables, in a park of 140 acres, purchased with a broad walk.

Beddington, near Croydon; W. Gee, Esq. Celebrated in the sixteenth and seventeenth centuries, and enlarged by his showing to Queen Elizabeth, who frequently visited him there. It is now in the possession of the Marquis of Titchfield, and the estate was let to the Duke of Norfolk. At present, Richard Cooper is the tenant. The house is placed in an advantageous situation, with a beautiful prospect. The present mansion was erected about 1750; the park contains some fine trees, and is admirably varied.

J. Gibbon, in an account of the gardens near London, written in 1694, says the gardens at Beddington was above 500 foot in length; that the trees were thirteen feet thick; and that the gardener had the house before gathered at least 10,000 oranges. The house is placed in a beautiful situation, and the house is in the possession of William Gee, Esq., his younger brother.

The Claremont, near Esher; Prince Leopold of Saxo Coburg. The park was chiefly planted by Kent, for Pelham Earl of Clarendon, and enlarged by his son, the Earl of Chesterfield, who planted the garden near the house, and the estate was let to the Duke of Norfolk. At present, Richard Cooper is the tenant. The house is placed in an advantageous situation, with a beautiful prospect. The present mansion was erected about 1750; the park contains some fine trees, and is admirably varied.

The present mansion was erected about 1750; the park contains some fine trees, and is admirably varied.
prいたor as a hunting-seat; the park surrounded by a hill of two
miles, and spotted with numerous clumps.

X Oldham Park.—near Guildford; Lord King. The grounds have
been lately much improved, the piece of water enlarged, and
the whole adapted to the modern taste.

Pepper Harrow.—near Haslemere; Lord Middleton. A good
manor, on the banks of the Wy, sheltered on the north and
west by rising grounds, covered with plantations; with an ele-
genent conservatory at the west end of the house, and a kitchen-
garden of three acres, containing a good range of hot-houses.

X Witley House.—Witley; Earl Spencer. A mansion by W. Holland, in
a park of 140 acres, agreeably divided into its surface, containing 
many distant views, and tastefully laid out by Brown, who formed a sheet of water, which covers
a space of 40 acres. The mansion-house of Witley was formerly 
one of the first in the kingdom. A survey of it was taken 
in 1334, and a copy of it is inserted in the 10th
volume of Archaeologia. The house was painted in fresco ex-
ternally, like the palace of Versuch; in the gardens was
an orangery, containing forty-two trees, in boxes, valued at $25.
each, lemons, citrus, pomegranates, figs; in the maze, wild-
flowers, knots, allee, were a great variety of trees and shrubs,
a bay-tree, and an Irish arboris. There was a mug milk ground
44 a at the end of the kitchen-garden, treached, mauled, and
very well ordered for the growth of musk melons. The house was
pulled down, rebuilt, burnt down, and rebuilt again in 1746.

Woodton House,—near Berkley; Hon. and Rev. J. Evelyn
Bowes. A seat of the Evelyns since the time of Elizabeth.
It contains the remains of no present dwelling, surrounded
by hills, clothed with cope-woods; but open to the south, and
considered one of the prettiest situations and most
gracious grounds round the house.

7529. Royal residences.

Kent.—near Brentford, the private property of the king,
was established by the Princess Dowager of Wales, in 1760, and
has been completely utilized, chiefly from the number of

7530. Sussex. A survey of 350,040 acres, gently varied, the soil
generally rich, great part bordering on the sea, consists of low undulating hills, or what may be called billy plains, kitchen
Downs (from Dun, Sx. a hill). The northern parts, towards Essex and Kent, abound in natural woods, or
remains of woods called wealds. This county is not remarkable for its gardening; on the coast, how-
ever, and especially about Worthing, the fig thrives better in the open air than it does anywhere else in England. The abundance of sea-shore gardens, described as the
great gardens of the shore, are the consequence of some commercial gardens near Worthing. These trees, and also the fig-orchard, of nearly an acre, at
Tarring, near Worthing, occupied by Loud, and containing 100 standard trees, have already been referred to.

7531. Of villas and mansions, the following are but a few of those deserving note:

Ashburnham Abbey,—near Beachy Head; Earl Ashburn-
ham. A spacious modern edifice, in the midst of an exten-
sive park, containing much fine timber, and a large sheet of water.

X Buxton Abbey,—near Tunbridge Wells; Marquis of Carew. A small, lofty edifice, lately completed; but the
defensive expense, and affording a solution for building,
for which a magnificent design has been given by H. Repton.
(Obervation on Landscape Gardening). Near the present
building the interior of old church and memorial have
been laid out as a flower-garden, which is much admired.

X Buckhurst Park,—near Lewes; Lord Whitworth. Both
house and ground have been created in the last ten or fifteen years
by this nobleman and his lady, the Duchess of Dorset.

Carton House,—near Westport; Lord Selsy. A small
place, too near a churchyard, and a small brook, which is dry
summer: the effect of both, however, much diminished by publicity.

Bredge Castle,—near Tunbridge Wells; Earl Abercromby.
An ancient castle, partly built of stone, and partly
built with round towers, but without any imitation of ancient architecture in the surrounding park, which
was laid out by a bold experiment, in a park of 3000 acres, well wooded and watered.

SEEDS OR PLANTS sent ther e from foreign countries, and the ex-
cellent description of them published in the Hortus Krieanus,
was collected by Sir Hans Sloane, and published in 1769, in one volume; that by the late W. Atlow in 1759, in
three volumes. Svo. The present catalogue, compiled in
1815, contains a description of the plants and vegetables, with a description of the house and gardens in 1765, with upwards
of forty plates, and they have also been the subject of two
poems, one by J. Ritto in 1763, and the other by Henry Jones,
author of the tragedy of the Earl of Essex.

From the first establishment of the garden, a number of collec-
tors have been sent abroad, and maintained there for the purpose of sending home plants and vegetables; and a great many names to the catalogue, because every plant is in-
cluded therein which has once been in the gardens; and
naturally, from want of that liberality in giving away or exchang-
ing plants, which might, to some extent, have been expected
an institution of this description, many of the plants which have been introduced are lost, and no where to be found but in the
catalogue. We have only to instance two precede-

A palace in the Gothic style was built by Geo. III. on the
banks of the Thames, the design is by Wyatt, and rather
crowded, the situation more beautiful than wholesome.
It has never been completed.

Richmond Park,—near Richmond. The palace long since
taken down; the park 25 acres, surrounded by eight miles of
brick wall. It is well wooded, and contains some large pieces of
water. A part of what is called the Old Park is reserved
by his present majesty as a dairy; the remainder constitutes the
royal gardens, which were first laid out by Hardeman in
1765, and afterwards opened and improved by Brown.
They have the advantage of being situated on the banks of the
Thames, and are bounded on the west by a broad and good road,
which was a private road, and a square road, and
around the gardens; one of which, called Merlin's Cave, contains the remains of some tombs; another, called
Laney's cave, was adorned with busts of Sir Isaac Newton, Locke, and other
literary characters. A description of these gardens was pub-
lished in 1753.

Seyhampstead.—near Chobham. A noble forest of trees, thickly
shaded with a rich variety of trees and shrubs; the house is in a
fine view of the surrounding country. The grounds much
improved by the late Dr. Lever, but at present in a very
ruinous state. The garden is divided into several
parcels, but the best part of it is near the house, and
is laid out in a rustic manner.

Whitefield Park,—near Windlesham; F. Newbury, Esq.
The park has been so well laid out, and well attended, as to be able to
keep in any game in its time; some of these hollies in the
house have been cut down for their timber.

Woodham, near Chigwell, Sir J. Snell. A spacious
Gothic mansion (fig. 742.), of cream-colored brick, and
in the most florid taste of that style of architecture,
arrangement, both internal and external, harmonious and
distinctly in the Gothic style, with a fine view on the
river.

Curzon Hall, near
Aruned; Sir C. Bishop. A singular old
Elizabethan house, not much altered either externally or
externally; in stately grounds. The mansion
is in a fine view of the surrounding country. The grounds much
improved by the late Dr. Lever, but at present in a very
ruinous state. The garden is divided into several
parcels, but the best part of it is near the house, and
is laid out in a rustic manner.

Whitefield House,—near Leves; Lord Sheffield. The
mansion stands low, in a park of between 3 and 500 acres,
long famous for its large oak-trees, and more recently so
for its extensive plantations, and for the care and judgment with which
these are managed in every part of the demesne, in 1400 acres of pleasure ground, and above
1400 acres managed as a park; the mansion house being the
front for which Lord Sheffield has been long celebrated.
GARDENS OF KENT.

1069

up Park,—near Eastonburn; Sir H. Featherstone. A magnificent house, and well wooded park; the timber-trees, in 1745, valued at 1069l.

3730. The following are first-rate residences:—

1. Arundel Castle,—at Arundel; Duke of Norfolk. A magnificent castellated structure, partly very old, and partly reappeared, and of the most various forms, from the most simple to the most complicated, forming a horizontal line, as if the rest of the park varied and was well wooded. The kitchen-gardens are good, and not inferior in scenery to the fisheries; and the house is partly old, partly new. Goodwood,—near East Grinstead; Earl of Egremont. A magnificent mansion, fronted with freestone, and surrounded by statues; in the front an artificial lake formed at an expense of not less than 30,000l., the water collected from numerous small springs, being held in an open vessel and conveyed in pipes. The park is 12 miles round. It was formerly little better than a waste; but is now well drained, and well stocked with every variety of British oxen, and also those of the Calabar, which were imported from the Cape of Good Hope, and the East Indies; the Scottish bison, and the shawl goat of Tibet. His lordship farms extensively, and has used every exertion to render his parks and woods in the highest degree picturesque rather than rural. The gardens and hot-houses are on a scale of design and cultivation suitable to every other part of this truly noble demesne.

3733. Royal residence.

1. The Pavilion, or Palace,—at Brighton, is in a mixed style of Chinese and Gothic architecture, and is by far the most elegant of the kind hitherto erected in the United Kingdom. The elegancies which the former greatly prevails. Exteriorly it forms a singular and beautiful edifice, and the inside has a perfect harmony in the division of the chambers, excepting the dining-room, the others are low or of different height, and are agreeable in a country seat, but not in an over-laboried in attempting to keep up the Chinese character. The grounds contain only a few acres, in which are a magnificent pile of marble buildings, and in which the house is erected by a dome partly glazed. The garden-scenery is tasteful, studded with the meanest flowers, and shows no exertions for approbation.

3754. KENT. A surface of 925,500 acres, considerably diversified by ridges of chalky eminences in some places; low marshy grounds on the Thames and Medway; open downs near Dover; and an inland, flat, and woody country round Sandwich, Deal, and the fens of the county, which contain 70,000 acres, belonging to three Duke, the Earl of Kent, and many other noble barons. Some parts of the county are very fine, and particularly about Maidstone, and on the road from London to Canterbury. The cottage and tradesmen's gardens on this tract are remarkably neat, perhaps more so than anywhere in the world, unless in some parts of Holland. It is also very productive in vegetables and fruits for the market, and in seeds of different kinds. It is divided into two halves, or two counties, of which one is larger, and belongs to a public, formerly a royal park; Philip Miller appears to have been born in this county, near the metropolis, but where is uncertain. The most celebrated gardens in former times were those of Knowle, and of Dr. Sherrard at Eltham.

3755. Further gardens.

1. Greenwich Park,—near Greenwich, originally belonging to Greenwich Palace, but that being formed into an Hos- pital for the incurable in 1511, William H. Shenstone, a poet, was the owner; it contains 185 acres, walled round by James I., and planted with elms and Spanish chestnuts in intersecting rows and avenues. Letter to Edmonds, in Charing Cross, near the Metropolis, from this park, is as interesting a thing of the kind as can be remembered.

3756. Commercial gardens.

1. Farmers' and Market Gardens,—abounding along the Thames, for the supply of the shipping. Immense quantities of green peas, beans, and potatoes, are raised, and in common farms land for the London market. At Sittingbourne, near Faversham, many great gardens are raised; and at Greenwich and Deptford great quantities of asparagus, onions, celery, potatoes, etc., are raised. At Deptford is the greatest grower of asparagus, and sometimes has 20 or 30 acres under this crop. An interesting place.

2. Orchards. These are chiefly about Lewisham, Maidstone, and along the banks of the Medway; the principal fruits of the coast are apples, pears, and plums, and in the country generally, on the hills, and near near Canterbury, belonging to Earl Cowper.

3. Market Gardens. There are many gardens of beans and seeds are grown for the seedmen; canary, radish, kidneys, and formerly turnip in the Isle of Thanet; tobacco or Sandwich beans at Sandwich, and in several other parts of the county. Various species of fruit are also raised here, a great deal of apples, and many canary-seed in the hundred of Herne. The county is also remarkable for the fine specimens of the improved rye-grass, collected from the county, and shipped for the seedmen of Faversham. About twenty thousand acres of this grass are raised, and the growth of onions for seed, the Deptford variety being in great request.

4. Market Market Gardens — there are two at Greenwich; and there are also some Florists' Gardens there.

5. The grounds of the country are not infrequently, though it must be allowed, that most of the orchardists raise their own trees. The principal is that of John Willmot and Co. of Lewisham. It was founded by Mr. John Russell, about the middle of the 18th century, who raised himself by his skill and industry, a fortune of his own. He has not the most of the other orchardists; and, after keeping his carriage, and living many years like a gentleman, he died in 1794, aged 81; and his son, who succeeded him, having married for the amount of 20,000l. The nursery is now carried on by his son-in-law, who employs from 200 to 300 men, and about 70 hands are employed, and about 3000l. a year paid for labour and scissorage.

6. The New Cross Nursery,—near Deptford, W. Cormack and Sons, is extensive, and has long enjoyed a respectable reputation.

5757. Cottage and villa gardens.

Cottage-Gardens.—Besides being nearer, as already mentioned, these gardens are stocked with finer kinds of vegetables, as they are nearer to the market. Many of the early potations, immense quantities of vegetables are raised in these counties; and they abound more in flowers than in any other part of the kingdom.

Farmers' and Market Gardens.—are rather inferior to those in most counties; fruit is here a necessary of life, everywhere cultivated; and that it is cultivated more and more, the ready market at Maidstone or London, or purchased by the fruit hawkers and agents who travel through the country.

Suburban Villas.—A few of these line the roads near the towns, and are particularly numerous along the Thames. There are a number round Blackheath, among villages of a large description. A few also exist round every town in the county, and all are highly kept.

Terrace-Gardens at Dover Castle.—The governor, quite fine. Four gradations or terraces cut in the shelving chalk and flint rock. On the barren cliffs and hills and vales are trained; the latters ripen in October, while in the low part of the town they seldom ripen at all. The whole in a state of neglect.

In Faversham, the snugly-built, spacious brick edifice on an elevation, rapidly declining towards the north, with fine views over the Thames to Essex; the grounds, the house, and the orchard, are all small, agreeably diversified, and well wooded.

Blenheim Hall,—near Belney; J. Smith, Esq. A good house, and the grounds agreeable, with some natural oakwood and parts of woods being agreeable. The owner, however, has greatly improved them, from the design of H. Repton.

Chariton House,—near Charlton; Lady Wilson. A good specimen of design of James I.; the park, though small, does not include some beautiful scenery, and fine old trees, especially cypresses.

Dunsor Hill,—near Belney; J. Johnstone, Esq. A handsome house, in a most agreeable situation, with lawns, shrubs, and coniferous trees, containing fine woods, and a spacious sheet of water, laid out by Brown.

Edna Farm,—near Beckenham; Lord Auckland. An elevated healthy situation, surrounded by fine boozes.

East Cliff Lodge,—near Runigate; Lord Keith. The house of a good specimen of modern Gothic; the grounds, which contain thirteen acres, are remarkable for a curious subterraneous passage 300 yards in length.

Goshamhurgh Place,—near Canterbury; F. B. Lepehiny, Esq. A handsome mansion, of a small size, and very agreeable. The park, however, has been altered, by G. Mason informs us, to much delight in improving the grounds.

Hidfield,—near Ashford; Sir T. E. Skulh, Esq. A square edifice of Portland stone; the grounds skirted by the Stour, and much improved in the taste of Sir W. Chambers. It is now in its time to agricultural pursuits.

Hill Park, near Westerham; J. H. Barrow, Esq. The grounds beautifully varied by nature, tastefully planted, and contains various trees of artistic kind; contains fine woods, and a spacious sheet of water, laid out by Brown.

Holwood House,—near Beckenham; the favorite retreat of the late prime minister Pitt. A small house, but the grounds extensive and beautifully laid out by H. Repton.

Leas,—near Ickham; T. B. Bridges, Esq. A Gothic mansion, well adapted to the situation; the grounds about the house displaying some fine thriving trees over undulating ground.

Quarry Hill, near Tunbridge; J. Burton, Esq. An eminent London builder. A castellated mansion by the roadside, built of the stones of the county, with many trees, etc. He has been called the builder of his time to agricultural pursuits.

Woodlands,—near Blackheath; J. J. Angerstein, Esq. An elegant mansion of Portland stone, in a commanding situation; the grounds planted in the taste of Sir W. Chambers, and well adapted for the quantity of glass they contain. There is a very large conservatory and some fine trees on a terrace raised; the pavement and execution of Mr. D. Stewart, when this gentleman's gardener; also an excellent orangery.
erected near Venice; the park well planted, and embellished with a cascade; the house has three storeys, and overlooks the ground.

Buntingford, near Seven Oaks; Duchess of Devon. A magnificent Elizabethan palace, the most modern part of which was built in 1603; it covers five acres. The park is between five and six furlongs in length, varying in breadth, and clothed with venerable oaks, beeches, ashes, and elms. The pleasantCapability, for the greater part, remains in their original taste, and contain some fine old oaks, cedars, and other trees. Extensive conservatories, modern mansion, and flower-gardens, with other improvements, have been added by the present proprietor, who is attached to gardening.

Note.—near Hasting—E. A. Colt—Formerly a castellated mansion, surrounded with a moat; now a splendid structure in the Gothic style, commanding fine views. "But having too much the air of a citizen's villa." The park is extensive, tinged with a bright green; a cascade; the approach to the house is through a broad sheet of water, and a handsome bridge.

Thalang, near Mons Horton; the late Lord Reayek. A large square brick house by Gibbs, with a park of 1000 acres, greatly improved in its pasture by the owner, who has been the prime mover in rejoicing the finest house in the Midlands.

Penshurst, near Tunbridge; J. S. Sydenham, Esq. An extensive and magnificent seat, including a park of 1500 acres; the park now reduced to 400 acres, but containing many fine old lime trees and a magnificent avenue of beeches. The houses and gates are tasteful, and the woods charming.

Summer Hill, near Tunbridge; W. Woodgate, Esq. A celebrated and beautiful seat, granted by Queen Elizabeth to the family of the Goelettes, near which place the Goelettes first opened it to the public. The house, situated in the centre of the grounds, is a pleasing mixture of old and new; the grounds richly wooded and highly picturesque.

750. ESSEX. A surface of 1,260,000 acres, of which one part, bounded on the Thames, is marshy, and chiefly under pasture; another part southwards is composed of the remains of Hainault and Epping Forests; and the remainder in the middle of the county, is cultivated in arable lands, on which, besides corn, the coriander, in pasture and gentleman's seats. There is a good market at Colchester for vegetables, and in the commoner garden-seeds are generally exposed for sale.

7540. Commercial, cottage, and farmers' gardens.

Farmers' Market-Gardens.—There are extensive in most parts of the county. About Ifford, Barking, and Plaison, immense quantities of early potatoes are grown for the London market.

Market-Gardens.—The principal of these are near the metropolitan counties, and at Chelmsford and Colchester; the latter town and Ely are, and Purfleet, supply the first early peas from the east end of the metropolis. Few of the market-gardens in this county, in Kent, or indeed any where, excepting those of Middlesex and Surrey, have much glass.

Seed-Gardens.—The London seedsmen receive more of their stock from this county than from any other. In the low districts on the Thames, great quantities of rape-seed are grown; brown and white mustard are grown in most places; and garden-cresses are raised, as well in Colles, Coggeshall, Colchester, and in the Isle of Mersea; carrot seeds at Walthamstow and Hornchurch, and many other kinds (Papaver somniferum, var. with blue seeds), round Coggeshall; from the marquis of Buckingham's woods at Gosfield Hall, near Braintree, and Hornchurch, of which town in Essex are procured, and hornbeam-seeds from Epping Forests.

Physic-Gardens.—There are none of these worth mentioning, one or two near Saffron Walden, in which the saffron is still cultivated for the apothecaries; but this article being brought so much cheaper from abroad, its culture in England has nearly given up.

Florists' and Nursery Gardens.—There are few of any consequence.

Cottage-Gardens, Farmer's Private Gardens, and Suburban Villas, 6,735; are abundant and in general very neatly kept; formerly the tradesmen of Chelmsford and Colchester were much attached to the culture of florists' flowers, and they still continue to do so in a considerable degree.

7541. Of Villas there are a considerable number, from which we select only a few.

Cooper'shall, near Thydon Germon; — Archer, Esq. A spacious edifice, surrounded by lawns and pleasure-grounds.

Braintree, near Melford; T. T. Gibbs, Esq. A handsome stone mansion, designed by H. T. Gibbs, surrounded by thriving shrubberies.

Eatingbury House, near Barking; — Sturry, Esq. An spacious house, with a spacious octagonal hall, and a large park; the grounds rather confined.

Pilks-Waltons, near Brentwood; T. Wright, Esq. An octagonal house, with chimneys in the centre; the grounds of limited extent.

Coppemedows, near Greensted; C. Ord, Esq. A neat house and good garden.

Beaton, near Stansted; J. H. Hoole, Esq. A desirable and pleasant residence, lately much improved.

Hare-hunt, near Eltter, J. Y. Monck, Esq. A spacious house, surrounded by a well-wooded park.

Hill, near Epping, J. H. Stowe, Esq. A grand seat, with extensive grounds, in the possession of the late Lord Crathorne, now belonging to the Esquire mentioned.

Thydon Germon, near Greensted; — Esq. A handsome house and garden.

Chelmsford, near Hadleigh; J. M. Tuffnell, Esq. A handsome house, in a pleasant situation, and the park and grounds well laid out.

Liton Hall, near Bexley; — Campbell, Esq. A handsome modern building, with plazas, encompassed by a small park and garden.

Marlow Park, near Misenden; — Sundys, Esq. A house in a park, which has been much improved in elegance, and rarely equalled for birch woods, picturesque, sequestered, and romantic scenes.

Tunstead Hall, near Tunstead; J. Marriot, Esq. A spacious handsome building, surrounded by pleasant gardens, over which is a bridge to the adjoining meadows.

7542. Mansion and demesne residences.

Audley End, near Saffron Walden; Lord Baybrooke. A magnificent Elizabethan structure, of which, according to Lord Walpole, John Thorpe and Bernard Jansen were the architects. The model was procured from Italy, and cost 500L. and the expense of erection was 19,000L. The park is fine, and contain great variety of trees, the pleasure-grounds were made from the designs of H. Repton.

Coughton Court, near Warley; J. Hatch, Esq. A neat house, and greatly improved scenery; the park contains some fine timber.

Culford Park, near Little Colne; P. Hills, Esq. A handsome mansion of white brick, surrounded with woods and plantations, amongst which are thickets of alder and holly, and groves of caraway, and hazel, are grown. The rest abounds in market for Colchester, and in the commoner garden-seeds are generally exposed for sale.

Coughton Hall, near Epping; J. Couper, Esq. One of the greatest ornaments of the county. The house, of white brick, has been designed by the Esquire's father, and contains much beautiful woodwork, intended for the house of his son. It is situated on a high ridge, to the west of which is a fine park, bounded by a line of tall trees, containing some of the greatest of the ancient and exotic, and many trees of the mighty, and of the rarest sorts. The house has a square plan; Sir W. Smith, a handsome quadrangular building on an eminence, with fine prospects over the fine park.

Ingestane Hall, near Ingestane; — Lord Petre. An irregular pile in a low situation, noted for its holly-hedges.

Higham Hall, near Woodford; J. Harman, Esq. The house is on a high ridge, to the west of which is a fine park, bounded by a line of tall trees, containing some of the greatest of the ancient and exotic, and many trees of the mighty, and of the rarest sorts. The house has a square plan; Sir W. Smith, a handsome quadrangular building on an eminence, with fine prospects over the fine park.

Graven Hill, near Gnosall; Marquis of Buckingham. A mansion of the domestic architecture prevalent in Henry VIII's reign. It is surrounded by a group of small houses, and shrubbery.

Hampton Hall, near Newport; — A. W. Wallenger, Esq. An elegant mansion of Portland stone, with wings joined by colonades; the pleasure-grounds are well laid out by Wood, a local nursery-gardener.

Higham Hill, near Woodford; J. Harman, Esq. The house is on a high ridge, to the west of which is a fine park, bounded by a line of tall trees, containing some of the greatest of the ancient and exotic, and many trees of the mighty, and of the rarest sorts. The house has a square plan; Sir W. Smith, a handsome quadrangular building on an eminence, with fine prospects over the fine park.

Ingestane Hall, near Ingestane; — Lord Petre. An irregular pile in a low situation, noted for its holly-hedges.

Lowestoft, near Woodford; J. Harman, Esq. The house is on a high ridge, to the west of which is a fine park, bounded by a line of tall trees, containing some of the greatest of the ancient and exotic, and many trees of the mighty, and of the rarest sorts. The house has a square plan; Sir W. Smith, a handsome quadrangular building on an eminence, with fine prospects over the fine park.

Narborough Hall, near Narborough; C. C. Weston, Esq. A neat modern building, and the grounds laid out with much judgment.

Audley End, near Saffron Walden; Lord Baybrooke. A magnificent Elizabethan structure, of which, according to Lord Walpole, John Thorpe and Bernard Jansen were the architects. The model was procured from Italy, and cost 500L.
7543. HERTFORDSHIRE. A surface of 302,080 acres, the north part forming part of a chalky ridge which extends across the kingdom in this direction, the rest agreeably varied. The soil is generally loamy over a subsoil of chalk, and there are a large number of small nurseries and market-gardens, and some orchards, to which are added a large number of vegetable-gardens. The gardens of Moor Park and Cashibury were formerly the most celebrated in the county.

7543. The villas are less numerous than the demesne-residences. Colonel Lord Norreys, near Watton, S. Smith, Esq. A spacious residence, sitting in a landscape garden, with a magnificent orangery and greenhouse; and a large collection of trees of every description. The garden is extensive.

7544. BUCKINGHAMSHIRE. A surface of 318,400 acres, hilly, and abundant in some places in natural beech-woods, the soil rich, and on chalk. It does not abound in gardens or residences, but contains one long celebrated—Stow. The seedmen procure many of their tree-seeds from the natural woods of Buckingham and Leicestershire, and, after the manner of nearly all the counties, they send out their haws, and juniper. Some of the nurserymen procure their stocks for standard roses from the same woods, and from copse-woods at their periodical felling, or when they are to be rooted out.

7547. Villas and demesne-residences. Baddules, near Beaconsfield; the Duke of Somerset. The mansion is a noble residence, containing 5000 acres, abounding in old oak and beeches. The gardens are extensive, and are surrounded by a large number of fruit-trees, and are laid out with great taste and judgment, and are stocked with many rarer sorts of fruit, and there is a magnificent orangery. The grounds are extensive.

7548. The following are first-rate residences:—

Gardens of Buckingham.
7549. BEDFORDSHIRE. A surface of 260,000 acres, and a strong clay in others. It contains the village of Sandy, on which the growing pickling cumburers, which are sent to the London market, and sold by the bushel.

Amphill Park, — Amphill; Earl of Upper Ossory. The mansion, a superb edifice, built in the Grecian style; the park contains 9000 acres, extensive and flat, but furnished some pleasant prospects; it has a fine water view, and many remarkable trees.

Luton Hoe, — near Luton; Marquis of Bute. The house is large and containing a good front by Adam; the library is 146 feet in length and 12 feet wide; the Hall on the first floor is extensive, well wooded, and watered by the river Lea, which runs near the house. The gardens of the farm which formerly kept in high order, but are now (1751) much neglected.

Freck, — near Selby; Barones Lucas (1600). An ancient seat, the grounds of which were submitted to Brown, who formed here a noble serpentine river, their principal ornament, and has occasioned this place being called the Stone of Bedford, which is occupied by half the farm, and contain many fine large trees.

The Duke of Bedford, — near Wiurham; Duke of Bedford. A first-rate residence. The abbey, or palace, is in the Ionic style, very extensive, and was much improved in the end of the last century. The entire mansion, with the garden and great apartments a covered way leads to a green-house, 140 feet in length, and a mile in circumference. The gardens resemble in nearly a quarter of a mile leads along the margin of a flower- garden, and are adorned Chinese building, ornamented with stained glass. The park is very extensive, varied in surface, and abundantly clothed with trees; but it wants one feature of essential importance, water. This might be given, but it would be at considerable expense. At present there are no such improvements, Small ponds or lakes have been effected in a general point of view, though some of them are pleasing, but they are not resemed on a large scale; the trees, contrived to fall in the way of the approach, is crossed by a viaduct (fig. 744.) designed by Repton. There are the remains of the old old and slender, silver and spotless cedars, one part of the park, which were planted under the direction of Miller; and there is a very tall beech with an erect stem, which has been noticed by Ponter. The garden is well-tended, and adorned by many rare trees, and the farm long been celebrated for the annual meeting of agriculturists, called sheep shearing, to which have been about 2000, and at which many of the agriculturists of the country, and many foreigners, are present. The late duke's passion for hothouses has been truly observed, did as an individual what is generally done by the body; he rewarded the artists engaged in this kind of industry, and gave a fair trial to every new agricultural scheme. The present duke has not the same taste, his father, brother, and sisters, who attended the annual meetings, and cultivates the park farm.

7550. HUNTINGDONSHIRE. A dull, flat, humid, unhealthy surface, of 240,000 acres.

Hinchinbrooke House, — near Huntingdon; Earl of Sandwich. A large and fine mansion, built of stone by the Duke of Portland's architect, in 1749, and slightly repaired by Hardwick's steward, about 1750, or later. (Plumtree's Residence in Ireland, p. 65.) The seedsmen receive a good deal of clever seed from Royston, and Clark is the principal nurseryman at Cambridge.

Public Promenades. — There are a few shady walks belonging to some of the colleges open to the public in general, and some private gardens; but none of them of any note.

Chipping Campden Park, — near Newmarket; John Thorp, Esq. A magnificent Dutch garden, with a large lake, and a spacious cascade, and with many other improvements, by which the ground and hedges have been greatly increased, and made very great improvements on the ground. The park contains a great number, and beautiful trees, and is 2400 acres in extent, three quarters of a mile in length, the joint work of the late Lord Eames and Mr. Lapidge. The hothouses form a range of many rooms, and are beautifully arranged and conducted. A large number of trees have been planted.

New Cumnor, — near Glingamby; Earl Hardwicke. The most splendid private residence in Cambridge. The mansion is a large brick structure; the park is extensive, but rather flat; the river Cam flows through it, and there are three lakes. The grounds are extremely well managed, and the farming establishment is eminently distinguished, and ranks with those of Wolbrum and Holkham.

7552. SUFFOLK. A surface of 800,000 acres, generally level, the soil sandy towards the sea, but clayey inwards. It is an old county, and contains some venerable seats and woods. Great quantities of peas are grown in the market gardens, and espand, and are very useful, and made very great improvements on the ground. Bois, — near Thetford; Duke of Grafton. A commodious house, surrounded by immense trees, and watered by the Ouse. The park contains a great number of old trees, and the seat of a great temple, built in 1769 for the Duke of Grafton and his family, in the neo-Grecian style, and was occupied by the estate. Bois, — near Thetford; Duke of Grafton. A commodious house, surrounded by immense trees, and watered by the Ouse. The park contains a great number of old trees, and the seat of a great temple, built in 1769 for the Duke of Grafton and his family, in the neo-Grecian style, and was occupied by the estate. Bois, — near Thetford; Duke of Grafton. A commodious house, surrounded by immense trees, and watered by the Ouse. The park contains a great number of old trees, and the seat of a great temple, built in 1769 for the Duke of Grafton and his family, in the neo-Grecian style, and was occupied by the estate.
Henham, near Henham; Lord Rous. An elegant modern mansion, and an extensive park and picturesque grounds, kept in excellent order.

Huntingdon Hall, near Huntingdon; Earl Dyvat. A house built in the time of Henry VIII.; surrounded by a moat, which, as well as the basin in the park, is, frequented by great numbers of wild fowl. The park comprehends 250 acres, and contains some of the finest old oaks in this part of the kingdom. There is a fine piece of water, and some fine and picturesque cottages, inhabited by a person, whose business it is to tend the sweet waters and splendid monuments of the Tollemache family, who possessed the estate in the reign of Edward I.

Hunston Hall, near Hunston; Lord Huntingfield. One of the finest seats in the county; the house a modern establishment, the mansion of Sir Robert Taylor, and finished by Wynn; the front 200 feet long, and adorned with Portuguese columns and an oriel upon an extensive parapet, which abounds in fine plantations, and is diversified by a noble piece of water near the house. The whole of this extensive property is surrounded by plantations, which, in a few years, will give a new character to this part of the county.

Ickworth Park, near Bury; Earl Bristol. An unfinished mansion, on a grand scale, from a design sent from Italy; the park is cut over in circumference, and containing 1800 acres.

7553. NORWICH. A surface of 12,900,000 acres; every where flat, flinty towards Lincolnsire; sandy in most places; and the rest a strong clay. It contains some good residences. At Norwich florists' flowers were first introduced into England by the refugee manufacturers from Flanders, about the middle of the sixteenth century. The principal nurseryman in the county is MacKay, of Norwich. The London seedsmen receive mustard-seed from Wisbeach, and some turnip and clover-seed from other quarters.

7554. Villas and demesne residences.

Baddings Hall, near Alysham; Right Hon. W. A. Harford. An interesting ancient mansion, surrounded with a moat, completed in 1628; the gardens, at that time, consisted of an elegant wilderness and lake. The park consists of 1000 acres, abounds in old trees, and the lake extends, in a crescent shape, for a mile, and its greatest breadth is 400 yards.

Belzington, near Cromer; Windham, Esq. A house partly of the time of Henry VIII., but subsequently enlarged; the park abounding in old wood, and greatly improved by the late possessor, whose taste in such matters is evidenced in his letter to42.

Gillingham Hall, near Yarmouth; Lord Beresford. A neat vettura, and extensive grounds, (fig. 745), with some fine old trees, a handsome piazza, and iron rails of an old church.

Cromer Hall, near Cromer; Lord Suffield. The park remarkable for its extensive plantations.

Hamwold, near Cromer; R. L. Doughty, Esq. An excellent small house, situated in a small but very pleasant park, well wooded, and laid out with great taste.

Hatfield, near Norwich; Sir M. R. Forbes. A residence lately much improved, and the gardens, hot-walls, and hot-houses, much increased.

Kinderley Hall, near Downham; Lord Woodhouse. A convenient house, in an extensive and beautiful park, richly ornamented with wood and water.

Rainham, near Wells; Marquis Townshend. A comfortable seat, built in 1675; the grounds, extensive, naturally suited for improvement, but not much improved.

Walmington House, near Walpole; H. L. Warner, Esq., 746.49

7556. OXFORDSHIRE. A surface of 450,000 acres, considerably varied by ridges, approaching, in some places, to the character of hills; the climate cold, and the soil in most parts thin, on a stony sub-soil. This county contains the magnificent residence of Blenheim; some others of great extent, and a botanical garden at Oxford. There are no commercial gardens in the county worth mentioning.

7557. Public gardens.

Public Promenades and College Gardens. — The promenades of Marchmont (Haddington) are unexcelled, and vary, consisting that they are merely walks round meadows on raised mounds, bordered by trees.

The public gardens are magnificent, and as well adapted for display as the others are for retired exercise or conversations. There are private gardens containing parts of the statues; their form is generally square or oblong, surrounded by a broad walk and intersected by other walks, some of which are used for their fit-rows, planted in 1644; that of Trinity for its verdant sculptures; and that of St. John's College, for being laid out by Brown, in the modern style, in 1775.

The Botanic Garden of Oxford was founded by Henry Earl of Danby, in 1625; it contains five acres, a green-house and a gardeners' house. The first curator was Hobart from Brunswick, in whose time, and in that of his son, who succeeded him in 1673, it was fuller worthy of notice than it has been since. Its present curator is William Baxter, A. L. S., and P. H. S.

7558. Villas and demesne residences.

Baddow, near Henley; J. Grove, Esq. Forty acres of pleasant-ground and a house; in the former a summer-house, from which fine views command of the park, and is surrounded by shrubs, the holly and other dark greens being placed in the foreground, and is adorned with a handsome piece of water.

Coombe Lodge, near Henley; S. Gardner, Esq. A flat piece of land, rendered interesting by every thing that art could effect by planting.

Grave Cottage, near Stonechurch; R. Davis, Esq. Truly an elegant cottage—neat; commodious, simple, and harmonised with the rural scenery around.
X Middlebroke, near Bicester; Earl Jersey, an excellent farm, but greatly injured, both as to the house and grounds by the present proprietor.  
X Mountsbourne, near煌ford, -- near Oxford; Earl Harcourt. A Grecian house, in part by Brown; the grounds laid out by this architect, but much injured, in part, and in part by Mason the pot. The park contains 1,074 acres, and a beautifully varied drive is conducted through it.

Slieveboragh Castle, near Watlington; Earl Macclesfield. Nonsuch mansion, on a bold and deep mound, approached by three drawbridges, the chief entrance guarded by a portcullis. The house is lofty, massive and very interesting; the pleasure-gardens have been lately improved; a flower-garden, a castle, a specimen of stone and cast-iron erected, and also a pavilion for the reception of flowers in the more genial summer months. The woods are magnificent. The villa contains upwards of 600 acres of rich pasture-land, skirted with wood, but rather flat. The house is ancient, and the garden and pleasure-grounds, now improving, contain a good conservatory.

X Wormald, near Steok Church: John Peete, Esq. The house is in an elevated site, the grounds of little beauty or beauty, but the proprietor an excellent farmer and breeder.

The Hedges, at Reading, is one of the finest examples of building in the abey style, of considerable antiquity; and which renders the celebrated author of Horace, Original Observations on Modern Gardening, is kept up in every improvement introduced in the pleasure-grounds.

7500. BERKSHIRE. A surface of 476,160 acres, finely varied by low hills and vales, the air healthy, and the soil good, and well cultivated. It contains numerous villages and mansions. The neighborhood of the market town of Reading has led to the establishment of the white market, which is a considerable market for the London market, and the seeds for the seedsmen, as well as asparagus grown both for the Bath and London markets: and there is a good nursery occupied by a man.

5501. Villas and demesne-residences.

Beaumont Lodge, near Windsor: Henry Griffiths, Esq. The house is in the Gothic style by Mr. Elwyn, architect, of Wroxton, and contains one hundred acres, sloping to the Thames, and finely varied by wood.

X Benham House, near Speen: Earl Craven. The house is in the same style, near the capital of Berkshire. It is an old place, celebrated in Observations on Modern Gardening, for the beauty of the approach, which is between two hills, with magnificently-rolled downs preceding their front, and approaching and retiring from the road in beautiful variation. The building is also extremely picturesque, and forming a comprising object of the surrounding country. The park is not extensive, but is much varied, so as to afford every variety of scenery, and the contents would indicate. The garden-scenery is agreeable; but the wooded grounds, as well as the house, are left to which Cadogan, with the assistance of Brown.

Chalcot Farm, near Wallingford: in 1800 the property of Lord Kemington, and formerly reputed to be the largest and most compact farm in England. Rent 1000 per annum. Before the house is an elevated site, the grounds of little beauty, the park well wooded, and enriched by views to Donnington Castle. It contains 2,000 acres, and is the residence of the Abbot of Reading, who had a seat here. The great horn in which his title to possession was contested, is 101 yards in length, and eighteen in breadth. The side walls are only eighteen yards wide, and there is a piece of ground 400 feet square, and is supported by seventeen stone pillars, each yard in circumference.

Cotswold, near Colestock: Viscount Folstone. The house is perfect and unaltered specimen of the taste of Inigo Jones, and contains sixty acres. The park is extensive. The park is not large, but is very agreeable.

Donnington Grove, near Speen: William Baggesen, Esq. The house is in the same style, and contains one hundred acres, sloping to the Thames, and finely varied by wood.

X Park Place, near Henley: Earl of Malmbury, son of the second Duke of Buckingham. The house is a large and impressive one, advantageously placed by Field Marshal Conway, and mentioned by the Prince de Ligne, in his Coup d'ceil sur les plus beaux jardins de France, as one of the finest seats in England. In the principal part of the house is a large room, with a magnificent view of the Thames for several miles. "The many interesting objects concentrated in this demesne, are calculated to excite even the most inattentive spectator. This is the result of a judicious plan which, with the elegance of the Thames, is kept up in every improvement introduced in the pleasure-grounds.

Sidney Park, near Sunning Hill: James Sibbald, Esq. The house is in the same style, near the seat of the Marquis of Bute, the largest and most elegant, and the scenery, which is richly diversified with stately trees and a large amount of ornamental water.

White Knights, near Reading: Duke of Marlborough (1820). The house is a plain building, situated in the centre of the woods, rather low, and close to an irregular sheet of water. This place is mentioned by Wheatley as one of the favorite seats of Lord North. The plan of the house is said to have been rendered it celebrated for its botanic riches, in which, if it does not surpass, it may vie with any residence in the empire. Wheatley has introduced to it a system of gardening of every kind, and another surrounded by a hedge and sunk fence, which are not destitute of picturesque beauty; there are also curious rustic huts. The whole has been lately described and beautifully improved by Gibbs, a character celebrated in the pencil of Mr. Hoffland. (See Description of White Knights, fol. 1813.)

X Upp Park Lodge, near Reading: James Wheelie, Esq. The mansion is a neat modern edifice, built by the present proprietor, and was tastefully laid out by Repton, who mentions this seat in his work. The park, having in 1817, been greatly enlarged and improved, the author of the present plan has employed to give designs, which, since have been executing works, there is a great improvement in the arts and trade, and considerable skill in rural improvements; and is a well informed man.

7505. Royal residences.

Frogmore (Frog-moor), near Windsor; the favorite residence of the Queen of George III. The house is not large, but neat; the grounds occupy a valley, one hundred acres, which is laid out in pleasure-ground, highly enriched by flowers and grass, with avenues of trees, and a large and varied collection of shrubs, and an artificial pond. The water, of irregular shape, and winding in different directions, is brought through a series of basins, connected with the main stream, and is surrounded by well-timbered woods, with varied and scattered objects. The whole is kept up in every improvement introduced in the pleasure-grounds.

The Queen's Lodge, near Reading: James Wheelie, Esq. The mansion is a neat modern edifice, built by the present proprietor, and was tastefully laid out by Repton, who mentions this seat in his work. The park, having in 1817, been greatly enlarged and improved, the author of the present plan has employed to give designs, which, since have been executing works, there is a great improvement in the arts and trade, and considerable skill in rural improvements; and is a well informed man.

Since the death of the queen, in 1818, the grounds have been extensively kept up by the female part of the royal family who reside there.

Windsor Castle. The principal residence of the British sovereigns. It was originally a hunting seat of William the Conqueror; improved by Henry I., and the park surrounded with a moat, by Henry II., and enlarged by Edward III. It is one of the finest architectural objects in England. There is a fine celebrated architect, William de Wyckham, who, in 1357, supervised the improvements of the park, and also the designs of Robert de Cotte; the grounds consist of 300 acres, the principal part of which is laid out as a ferm orne. A fine ride, of about three miles, passes between the woods and the castle, and the scenery, which is richly diversified with stately trees and a large amount of ornamental water.

7563. GLOUCESTERSHIRE. A surface of 600,000 acres; elevated, hilly in many parts, and the climate cold, water, fertile, and humid, however, on the banks of the rivers, where the land is more open, and the streams larger, it is much more favorable, and a very considerable extent of land is cultivated. The borders of Monmouthshire are some woods of lime-tree, from the bark of which ropes are made for fishing and agricultural purposes. There are a number of nurseriesmen in this county, of which the principal are
GARDENS

Moseley, Lamotte, Rt. crab-stocks, Lord W. Jr the Prior.

Amanure

a mansion designed from Birmingham situation; Broomsgrove, very dated and tourists Hagley,—

Cleeve, a very wooded and enlivened place, with its circumference, and surrounded by fine beefe woods.

Barrington is a mansion, is elegant three miles from Arkwright; is erected in a fertile, wooded, and well-peopled site, and surrounded by a piece of water, the Wenlock Deuce, which, at times, is roared upon by weirs.

The house, near Winchcombe; Snell, Esq. the house is a noble mansion, near Newnham; Lord Gage. A noble mansion.

acres; hilly in many places, as at Malvern and Worcestershire, but in general low and very fertile, as in the Cotswolds.

Blackmore Park, — near Malvern; T. Hornsby, Esq. An elegant mansion, lately built, situated on a rising lawn, studded with plantations in an elegant style of improvement.

Hill Road, — near Tewinbury; Esq. A noble mansion, lately built, situated on a rising lawn, studded with plantations in an elegant style of improvement.

Hill Road, — near Tewinbury; Esq. A noble mansion, lately built, situated on a rising lawn, studded with plantations in an elegant style of improvement.

Tackwell, near Sydenham; Esq. A noble mansion, lately built, situated on a rising lawn, studded with plantations in an elegant style of improvement.

Hill Road, — near Tewinbury; Esq. A noble mansion, lately built, situated on a rising lawn, studded with plantations in an elegant style of improvement.

Hill Road, — near Tewinbury; Esq. A noble mansion, lately built, situated on a rising lawn, studded with plantations in an elegant style of improvement.

Hill Road, — near Tewinbury; Esq. A noble mansion, lately built, situated on a rising lawn, studded with plantations in an elegant style of improvement.

Hill Road, — near Tewinbury; Esq. A noble mansion, lately built, situated on a rising lawn, studded with plantations in an elegant style of improvement.
extensive, and finely diversified with variegated features, soft and abrupt undulations, and achievements, covered with noble plantations of oak, beech, and Spanish chestnut.

Troy House, — near Monmouth; Marquis of Worcester. A house by Inigo Jones, on the banks of the Towy. This seat was famed for its gardens in Charles II.'s time, and especially for its famous flower gardens on the south frontage of the Marquis of Worcester, it is stated that "Sir Thomas Somerset, a very complete gentleman, delighted much in fine gardens and orchards. The same gardens were famous in Henry VII.'s time, when in possession of William Herbert, who, as we are informed by Evans (Letters on Wales, 1811), sent two men, by the names of Richards and Williams, to France and Flanders, for the express purpose of studying horticulture, and importing foreign vegetables and choice fruit-tree.

753. HEREFORDSHIRE. A surface of 600,000 acres; much varied by hills, some of which approach the nature of mountains; it is covered by an extraordinary variety of woods, and in ploughed ground grass or charls; and the soil is everywhere deep and rich. Hereafter to be celebrated in gardening history as being the birth-place or residence of Uvedale Price and R. P. and T. A. Knight.

Brockhampton, near Ledbury; — Matthews, Esq. A romantic situation on the Wye.

Berrington, — near Leominster; Rt. Hon. T. Harley. A splendid scenery, of picturesque situations, in a picturesque valley, very singular; and the villa, built by his late owner, Sir Henry Basset, the celebrated author of The Landscape, a poem; of the Analytical Inquiry into the Principles of Taste, and other elegant productions. The house is built with towers, and embattled walls, but internally finished in the Grecian style. The park abounds in innumerable statues, and the whole is decorated with nature, and not far distant is a pear-tree which covers nearly a quarter of an acre.

Hortons, — near Ledbury; J. M. Bartet, Esq. The house and grounds recently improved from our designs; the latter highly romantic by nature, and well wooded.

Kinchurch, — near Llanfoist; J. Scudamore, Esq. (Discerning, Enquir & Amours, square or assistant in love matters.) A pleasant situation, with a park of three or four miles in circumference.

Longmynd; — near Bromyard; J. Walwyn, Esq. A good mansion, recently erected, and the grounds well timbered.

Llandinam; — near Llanfoist; Sir L. Llewellyn. A plain brick mansion; but the grounds richly wooded.

Llancarfan, — near Bridgend; — Mr. A. Cornwell. A good house, delightfully situated on the southern bank of the Wye, with a large park, finely clothed with oak, and remarkable for a variety of that tree with weeping spray. The only other specimen we know of is in the botanic gardens at Amsterdam. The growth of the oak in this part of the country, has been such as to render it useful nearly everywhere.

Rothera, — near Hereford; C. Bodenham, Esq. A spacious brick mansion, and grounds containing some good timber.

Shobdon Court, — near Martyn's Cross; Lady Bateman. An elegant seat; the park between three and four miles in extent, contains rich and picturesque scenery.

Stoke, — near Bromyard; Lord Foley. A spacious brick house; with a terrace in front; the park and grounds well wooded, and considerably improved under the direction of H. Repton.

Wotton Court, — near Hereford; Esq. A handsome mansion of Bath stone; the grounds improved by D. A. Repton.

Longmynd; — near Bromyard; J. Walwyn, Esq. "A good mansion, recently erected, and the grounds well timbered."

754. SHROPSHIRE. A surface of 940,940 acres; mostly flat, with some hills; the soil generally good. It contains a number of good nurseries, and sends to London baking-plums and walnuts in large numbers. The long been, a place to excite wonder, and also agreeable

Aston Park, — near Oswestry; W. Lloyd, Esq. A most elegant seat, in a highly natural situation, the grounds much improved by the correct taste of the owner.

Bentley Hall, — near Shrewsbury; Lord Hill. A good mansion, on a beautiful slope on the north side of a romantic hill; the grounds extensive, and containing beauty and agreeable variety; the park contains most romantic walks, a hermitage, and many other buildings and monuments;—in short, it is a fine natural preserve, formed along a slope, and everywhere the finest trees. On the whole, it is, and has long been, a place to excite wonder, and also agreeable

The Lawoues, — near Hales Owen; — J. P. Quin. A pasturage, chiefly celebrated for having been the residence and the creation of Shenton. Some of the root-houses and grotsies in the path which lead along the hedge, and in the strips of common, are very remarkable.

Oakley Park, — near Ledlow; Lady Oliver. The mansion on the hill; the park between three and four miles in extent, naturally romantic, and laid out with much taste and judgment.

755. SUFFOLK. A surface of 750,800 acres; hilly and moory towards the north, but plain lands in the south- east; it contains a number of villas and mansion-residences, and nurseries are numerous.

Rude state (fig. 747), by the late Earl of Uxbridge, who, with the aid of H. Repton, formed a large piece of water, and of land; and, to please the reason, and render the house more conspicuous. (fig. 748.)

Hersham, — near Llanfoist; Sir H. Hodygn. The mansion lately improved; the park well wooded.

Itola, — near Llanfoist; — Matthews, Esq. A romantic situation on the Wye.

Bridgenheath, — near Newport; Sir T. Broughton. An elegant seat, surrounded and shaded by many pines, and by some young trees, and is formed by a number of plantations of indigenous trees, especially sycamores. The park is divided by the road, and yields annually from twelve to sixteen hundred, the opposite part to that in which the house stands.

Narford, — near Narford; — Emson Stanford. The house, a large brick structure of an imposing Gothic character; the grounds formerly celebrated, but now chiefly remarkable

It is rich in large oaks and picturesque views. Lord Bacton pays considerable attention to horticulture, and cultivates success- ful experiments in the cultivation of hardy deciduous trees. The Horticultural Society's Transactions.

Broughton Hall, — near Newport; Sir T. Broughton. An elegant seat, surrounded and shaded by many pines, and by some young trees, and is formed by a number of plantations of indigenous trees, especially sycamores. The park is divided by the road, and yields annually from twelve to sixteen hundred, the opposite part to that in which the house stands.
Gardens of Derbyshire

Hagley Hall, near Ragstone; Lord Curzon. A finely situated residence, the park and gardens having been much enlarged and largely improved.

Little Aston, near Tarvin; a splendid garden, surrounded by lawns and trees, and embellished with a large mole lake. Over the latter is thrown a very handsome stone bridge, and opposite to it stands an elegant stone conservatory.

PRESTWIXE, near Dudley; Sir Thomas Littleton. A fine modern house, the surrounding pleasing grounds exhibiting a most delightful variety of hill and dale, wood and water, effectually clothed by the hand of nature.

Sandon, near Newcastle; Lord Harrowby. An elegant mansion, finely situated on the declivity of a considerable eminence, commanding noble and luxurious prospects.

Sandwell Park, near West Bromwich; Earl Dartmouth.

7571. WARWICKSHIRE. A surface of 639,700 acres; elevated, not much varied, well wooded country. There are many neat cottages, but none in the county, especially near Coventry. The principal market-gardens for the commoner culinary crops near that place. An Ashley Hall, near Oldbury; I. N. Ludford, Esq. An irregularly disposed. A Moor Park, near Stafford; Earl Talbot. A respect- able Elizabethan edifice, surrounded by grounds in the ancient style, but in a great degree modernised by the present proprietor.

7572. The following are first-rate residences: The county.

Oceole Abbey (Crom, or Cobbe, a low or hollow place), near Coventry; Earl Craven. A noble mansion, in part by Inigo Jones, in a part of 600 acres, well wooded and watered.

Agby Hall, near Alveston; Marquis of Hertford. A spacious mansion, improved by Wyatt, on the summit of a round knoll, surrounded by extensive plantations of trees, and also in young plantations, with a fine lake and every feature worthy of this noble seat. The kitchen-gardens are noted for the extent of their hot-houses, and for the cultivation lake of the pine-apple, especially of the Providence kind.

7573. A Warwick; Earl of Warwick. A very ancient Gothic structure, on a steep rock rising from the Avon, with a large garden-court, flanked by towers, and with a gate and portico, Sir in a truly baronial style, and in an excellent preservation. The park is very extensive and finely wooded by the house, and watered by the Avon, as well as some artificial lakes. The pleasure-gardens contain a fine course of broad gravel walks, some handsome lawns and avenues, and a good succession of trees; low, generally flat, and one of the richest gravel counties in England. It does not abound rich, have seldom good gardens.

7574. DERBYSHIRE. A surface of 720,640 acres; hilly, irregular, and in some parts mountainous; the valleys rich and beautiful. There is a good nursery and florists' garden at Derby, by Joseph Mason, and some neat cottage-gardens in the county.

Wooler, near Derby; Sir R. M. Wilmot. A neat villa, with a good kitchen-garden.

Chadderwood, near Derby; Sir R. M. Wilmot. A neat villa, with a good kitchen-garden.

Forewords, near an ex-Sir Francis Bourdett, Bart. The house is an elegant and substantial modern building; and the park and gardens respectably terminated.

Locke Park, near Locke; William Drury Lowe, Esq. The grounds are naturally much varied, and contain a handsome artificial lake; but the plantations having been made when the geometrical taste was in fashion, do not accord well with the various parts of the country.

Osbaston, near Derby; Sir Robert Wilmot. The house is a magnificent specimen of ancient architecture; the grounds were laid out by blamed; the pleasure-gardens occupy five acres, and are very agreeably disposed.

Horton Hall, near Derby; Lady Banks. In the garden a quadrangular brick building, situated, a romantic valley, shaded with trees, and crowned with the highest degree of taste and judgment.

A Shugborough, near Lichfield; Lord Anson. An elegant (recent) mansion, in a low situation, watered by the Trent. The grounds were laid out at great expense by the late Thomas Anson, Esq., and contain numerous and well-executed ornamental buildings, in different styles of architecture. The present residence is chiefly disposed of by private means, is in a very agreeable manner.

Trent Hall, near Newcastle-under-lyne; Marquis of Stafford. A low situation, with abundance of water, and some rising grounds. Great expense has lately been incurred on the house, and a fine modern brick building is the principal feature. The kitchen-gardens are extensive, and contain numerous hot-houses, and for the cultivation lake of the pine-apple, especially of the Providence kind.

Rugeley Hall, near Rugeley; Marquis of Hertford. A spacious mansion, improved by Wyatt, on the summit of a round knoll, surrounded by extensive plantations of trees, and also in young plantations, with a fine lake and every feature worthy of this noble seat. The kitchen-gardens are noted for the extent of their hot-houses, and for the cultivation lake of the pine-apple, especially of the Providence kind.

7575. An ancient Gothic structure, on a steep rock rising from the Avon, with a large garden-court, flanked by towers, and with a gate and portico, in a truly baronial style, and in an excellent preservation. The park is very extensive and finely wooded by the house, and watered by the Avon, as well as some artificial lakes. The pleasure-gardens contain a fine course of broad gravel walks, some handsome lawns and avenues, and a good succession of trees; low, generally flat, and one of the richest gravel counties in England. It does not abound rich, have seldom good gardens.

Lockington Hall, near Keyworth; Rev. P. Stoney. The grounds contain a magnificent specimen of ancient architecture; the grounds were laid out by blamed; the pleasure-gardens occupy five acres, and are very agreeably disposed.

7576. Ilmington Hall, near Ilmington; Sir J. Pickie, Esq. A large mansion and fine wooden panes, with pleasant grounds.

Skeffington Hall, near Rugeley; Marquis of Hertford. A spacious mansion, improved by Wyatt, on the summit of a round knoll, surrounded by extensive plantations of trees, and also in young plantations, with a fine lake and every feature worthy of this noble seat. The kitchen-gardens are noted for the extent of their hot-houses, and for the cultivation lake of the pine-apple, especially of the Providence kind.

7577. An ancient Gothic structure, on a steep rock rising from the Avon, with a large garden-court, flanked by towers, and with a gate and portico, in a truly baronial style, and in an excellent preservation. The park is very extensive and finely wooded by the house, and watered by the Avon, as well as some artificial lakes. The pleasure-gardens contain a fine course of broad gravel walks, some handsome lawns and avenues, and a good succession of trees; low, generally flat, and one of the richest gravel counties in England. It does not abound rich, have seldom good gardens.

Winkworth, near Chesterfield; Sir William Hunlock.

A noble seat, surrounded by extensive plantations, and being on one side of the Dove. The kitchen-garden and hot-houses are good and splendid, and the pleasure-gardens are extensive.

Wingfield, near Chesterfield; Sir William Hunlock. A noble seat, surrounded by extensive plantations, and being on one side of the Dove. The kitchen-garden and hot-houses are good and splendid, and the pleasure-gardens are extensive.
575. The following are first-rate residences: —

Χ Chatworth, — near Bakewell; Duke of Devonshire. The most magnificent house in the county. The situation is most beautiful; the aspect is grand; the edifice is large; the park is immense; the ground is perfectly level; and all the objects are highly pleasing. The gardens are extensive; the park is universally admired; the edifice is magnificent; and the whole is eminently beautiful.

Χ Haddon Hall, — near Bakewell; Duke of Rutland. One of the most elegant and commodious houses in the county, and, though not inhabited, kept in good repair. The extent of the building, and the number of apartments and offices, are calculated to accommodate any number of persons, and every room is elegantly furnished.

ζ Kirklington Hall, — near Southwell; Mrs. Belsham. A large edifice, with an undulating lawn, descending to an undulating meadow; a highly enriched bridge, and a fine view of the river. The gardens are extensive, and the situation is lovely.

ζ Kelmarsh Hall, — near Mansfield; Lord Denison. The building, and such of the grounds as have been purchased by this gentleman, are undergoing improvements: but the place is charming, and the situation is delightful. The gardens are extensive, and the park is highly interesting.

ζ Cleeve Court, — near Worthing; Duke of Newcastle. A large house; the park containing 4000 acres, and eleven miles in circumference, with a magnificent castle, and various temples, tombs, and monuments. The edifice is magnificent, and the park is highly interesting.

ζ Wollaton Park, — near Nottingham; Sir J. Clifton. A large park containing 7578 acres, and numerous edifices. The gardens are extensive, and the situation is delightful.

576. NOTTINGHAMSHIRE. A surface of 436,500 acres; generally genial, fertile, dry, and healthy, containing the chief, or most of the extensive forests of Sherwood. There are many market-gardens and orchards at Retford and Nottingham, and tree-seeds are collected about Worksop and other places.

ζ Osprington Hall, — near Lenton; J. Denison, Esq. The house is of stone, and built by Elizabeth Countess of Shrewsbury, whose passion for building is well known: it is also celebrated as having been the place of confinement of Mary Queen of Scots, who was afterward removed to Seaby, and contains the ruin of a former castle, in which is a room, said to be the place where Mary was delivered of her son. The park contains 7800 acres, and is considered as having been thought a fit pattern of measure and contrivance of the kind. The gardens are extensive, and contain all sorts of flowers and fruits, and are particularly beautiful.

ζ Keddleston — near Derby; Lord Scarsdale. The house is a Grecian pile by Adams, and one of the handsomest in England, and is considered as the noblest residence in the kingdom.

ζ Studham, — near Newark; Sir J. Stapleton, Esq. A noble mansion and gardens; the gardens, pleasure-grounds, and extensive.

ζ Trowbridge Hall, — near Etwall; J. W. Emmerson, Esq. A mansion in the style of James I; the gardens neat and agreeable, and the surrounding scenery picturesque.

ζ Welbeck Abbey, — near Worksop; Duke of Portland. A large and magnificent house, in a lonely situation, and containing in the time of Spencyl, but for many years neglected. The park, being part of the forest of Sherwood, abounds in old oaks, and contains numerous young plantations of oak, birch, sycamore, and other trees.

ζ The Old Hall, — near Nottingham; Lord Middleton. A square structure, with towers at the angles, and an ele- gant park, and situated in a most delightful situation, in Queen Elizabeth's time. It is approached by a winding avenue, with trees, and bounded by ancient oaks, which are considered as one of the handsomest in the kingdom.

ζ Rocky Hill, — near Nottingham; Sir J. Stapleton, Esq. An elegant building with plantations, and grounds very extensive.

577. LINCOLNSHIRE. A surface of 1,783,680 acres; great part on the sea-shore, flat and ferry; the wolds, which occupy the north-east, as the word (Saxon) imports, are hilly and void of wood. The Lincoln seedsmen receive hemp, turnip, rape, and quantities of parsley-seed, which the farmers sow in the spring. Some garden-seeds for the supply of the Yorkshire seedsmen are grown in the Isle.

ζ Burnell Park, — near Barwell; B. Lester, Esq. A handsome mansion, in a commanding situation, surrounded by extensive grounds. The park contains 7578 acres, and is well wooded, and surrounded with outbuildings and thriving plantations.

ζ Newstead Abbey, — near Lincoln; General Bortie. A fine old house, in a commanding situation, and surrounded by thriving plantations.

ζ Gainsborough Castle, — near Gainsborough; Duke of Ancaster. An irregular pile, chiefly by Vanburgh, on a beautifully undulated lawn, descending to two lakes, comprising about 400 acres, besides which is a rising ground covered with trees. The park is one of the most extensive in the kingdom; there are three ridings in it, each four miles, in a straight line and in different directions. There are some rough forest scenery and great expanse of rich pasture. The lakes have been much improved since it was intended, and there would have existed here one of the most magnificent pieces of artificial water next to Blenheim.

ζ Cadby Hall, — near Lincoln; General Bortie. A fine old house, in a commanding situation, and surrounded by thriving plantations.

ζ Croxton Park, — near Gainsborough; Lord Bexhilton. A large mansion, surrounded by an extensive lawn and pleasure-grounds.

ζ Longthorpe Park, — near Deen; Earl of Cardigan. A low embattled structure, with a tower terminating each wing; the ground beautifully varied, well wooded, with a fine piece of water, an island, and various ornamental buildings.

ζ Uphord — near Brington; Lord Spencer. A large pile, dated 1685, in a park distinguished by large masses of wood, and of various surfaces.

ζ Castle Ashby, — near Asby; Earl of Northampton. A large and magnificent mansion, in a park containing a large lake, by Brown.

ζ Merchiston — near Linlithgow; Sir G. Robinson. A mansion-house, surrounded by an extensive lawn and pleasure-grounds.

ζ Whimple Park, — near Dean; Earl of Cardigan. A low embattled structure, with a tower terminating each wing;

ζ Pensons House, — near Wreley; E. Turner, Esq. A house by Hawksmoor, a pupil of Sir John Vanbrugh, afterwards designed by Sir Carr of York; the park much improved by plantations.

ζ The Park, — near Glinton; Sir G. Heathcote. The house, one of the most splendid old houses and spacious parks in the kingdom; the house in the Elizabethan style; the park magnificently laid out by Brown, who formed a handsome expanse of water, and constructed many immense and beautiful plantations; the house to form a lawn. A copious account of this place, with views, has been published by Sir Dr. Daskell, of Stamford.

ζ Eaton Hall, — near Stratton; Mr. Noel, Esq. A grand residence, with extensive gardens, and new arrangements, in the ancient style, by London and Wise; the gardens have been improved, and the water and contents made more extensive.

ζ Normanston House, — near Normanston; Sir G. Heathcote. A well-plantanted and well-paved park of 400 acres; and gardens neatly laid out.

ζ Hatfield House, — near Pavey; Lord Scarsdale. A moated building of different ages; the park, a fine improved demesne, abounds with the rarest and most elegant trees; and the gardens are among the most extensive and splendid in the kingdom.

ζ Kirnmarth, — near Kelmarsh; W. Hanbury, Esq. A large and magnificent house, in a park, extending over 3000 acres, and diversified with the contrasted positions of wood and water.

ζ Rushden Hall, — near Rothwell; — a very exquisite and disposed seat, by the late possessor the Hon. W. Coke.

ζ Appleton Tree, — near Middleton; Lord Malwood. A noble elms, and a large number of trees; the park is extensive, and well wooded.
GARDENS OF YORKSHIRE.

Upton Hall,—near Northampton; T. S. W. Sanwell, Esq. A large mansion, set in a gravelly soil, displaying fine views of the distant scenery.

7581. YORKSHIRE. A central, and, in part, maritme county, of 3,689,380 acres; the surface varied, containing several mountains, extensive moors, and some royal forests; the subsoil most generally rocky in the northern part, and botanical in the southern part. At Hull, a considerable town. At the north end of the county, and in the large towns. It abounds in residences, especially in the West Riding, where nearly 400 are mentioned in The Beauties of England and Wales, as worthy of notice. The farmers' gardens are kept in a good state in the better parts of the county; and at Leeds there are some neat cottage-gardens, on the verge of the town, and on the borders of the water, and thrives on limestone soils, and the fruit is sent to Hull, York, London, and other markets. There is a horticultural society held at Leeds, the chief promotor of which is J. Carr, of St. Anne's; and the same gentleman is active in his endeavors to set on foot a botanical garden. Chepel Allerton, near this town, was visited by the public recently. By W. Smith, Esq. of

Brougham Hall,—near Kirkham; Geo. Cholmley, Esq. A large and elegant mansion, on a swell rising from a beautiful park; the pleasure-grounds finely embellished with plantations, with fine colored flower-beds, and other ornamental walks.

Hofstore,—near Howden; Hon. W. Stuart, Esq. A seat on a moor, near the sea; a very fine taste is displayed, and no great expense, a range of pleasure-grounds, which, in magnitude, convenience, and picturesque beauty, not many places in England could excel.

Kirkleigh Hall,—near Gilpin; H. Vansittart, Esq. An excellent mansion, near a garden, the extensive laid out with much taste; they contain an octagonal temple, and with gardens, which, with extensive prospects so general in the county, are very fine. (See also Brougham Hall.)

X. Wolgreave Grange,—near Whitby; Earl Maltrav. A Gothic house in a situation on the sea-coast; the approach by a fine avenue, admired, and the views of the surrounding scenery views both very extensive.

Necely Hall,—near Brough; Lord Grantham. A brick mansion, supposed by Sir C. Wren, in 1700; the pleasure-grounds laid out with most correct taste.

Dunham,—near Rockingham; Sir H. Varvano. A handsome gentleman's residence, in a flat country; a very fine range of pleasure-grounds, with extensive views.

Ronen-on-the-hill,—near Doncaster; R. F. Wilson, Esq. A good house and fine grounds, with those extensive prospects so general in the county, which are very fine. (See also Necely Hall.)

X. Wolgreave Grange,—near Whitby; Earl Maltrav. A Gothic house in a situation on the sea-coast; the approach by a fine avenue, admired, and the views of the surrounding scenery views both very extensive.

Necely Hall,—near Brough; Lord Grantham. A brick mansion, supposed by Sir C. Wren, in 1700; the pleasure-grounds laid out with most correct taste.

Dunham,—near Rockingham; Sir H. Varvano. A handsome gentleman's residence, in a flat country; a very fine range of pleasure-grounds, with extensive views.

Ronen-on-the-hill,—near Doncaster; R. F. Wilson, Esq. A good house and fine grounds, with those extensive prospects so general in the county, which are very fine. (See also Necely Hall.)

X. Wolgreave Grange,—near Whitby; Earl Maltrav. A Gothic house in a situation on the sea-coast; the approach by a fine avenue, admired, and the views of the surrounding scenery views both very extensive.

Necely Hall,—near Brough; Lord Grantham. A brick mansion, supposed by Sir C. Wren, in 1700; the pleasure-grounds laid out with most correct taste.

Dunham,—near Rockingham; Sir H. Varvano. A handsome gentleman's residence, in a flat country; a very fine range of pleasure-grounds, with extensive views.

Ronen-on-the-hill,—near Doncaster; R. F. Wilson, Esq. A good house and fine grounds, with those extensive prospects so general in the county, which are very fine. (See also Necely Hall.)

X. Wolgreave Grange,—near Whitby; Earl Maltrav. A Gothic house in a situation on the sea-coast; the approach by a fine avenue, admired, and the views of the surrounding scenery views both very extensive.

Necely Hall,—near Brough; Lord Grantham. A brick mansion, supposed by Sir C. Wren, in 1700; the pleasure-grounds laid out with most correct taste.

Dunham,—near Rockingham; Sir H. Varvano. A handsome gentleman's residence, in a flat country; a very fine range of pleasure-grounds, with extensive views.

Ronen-on-the-hill,—near Doncaster; R. F. Wilson, Esq. A good house and fine grounds, with those extensive prospects so general in the county, which are very fine. (See also Necely Hall.)

X. Wolgreave Grange,—near Whitby; Earl Maltrav. A Gothic house in a situation on the sea-coast; the approach by a fine avenue, admired, and the views of the surrounding scenery views both very extensive.

Necely Hall,—near Brough; Lord Grantham. A brick mansion, supposed by Sir C. Wren, in 1700; the pleasure-grounds laid out with most correct taste.

Dunham,—near Rockingham; Sir H. Varvano. A handsome gentleman's residence, in a flat country; a very fine range of pleasure-grounds, with extensive views.
8738. DURHAM. A surface of 610,000 acres, rich in pastures and woodlands towards the east this county.

Basingallough Hall, near Stanstead; Sir P. Parker. A small house, in a pleasing situation, but elegant.

Beaulphall Lodge, near Hockley; the house is an elegant building designed by J. Johnson, Esq. with an observatory.

Brown's, near Birtley; the present house, which is considered greatly enlarged and improved by the present owner. There are some valuable ornamented grounds in the buildings, and especially a superb mausoleum.

Cassilis, near Holme; C. S. Duncumbe, Esq. A superb house, by Vanbrugh, which a consultation affords delightful prospects over a fertile valley to wooded hills, with a fine Ionic temple, and other buildings, and abound in fine trees.

8734. DURHAM. A surface of 1,157,780 acres, much varied by hills and mountains; for the most part surrounded and alternately broken up by the growth of onions, and there are extensive nurseries at Gateshead, and for the cultivation of garden flowers.

Mr. and Mrs. Jones, near Wark, Esq. A delightful residence, with woods, rocks, and waters, and scenery in all respects pleasing.

Goloth House, near Newcastle; S. J. Brindley, Esq. A mansion by Pain, and the grounds surrounded by a broad belt of trees, with a pleasing view of the town and river, a beautiful expanse of water, by White.

Hedgeley Hall, near Newcastle; M. W. Bidley. An elegant house by Newton, the translator of Virgil, erected in 1715, on the steep and woody banks of the Tyne, near Warkworth. The house is surrounded by high and bold rocks, and hanging woods that screen the view, being in high keeping forms the finest contrast.

8757. First-rate residences.

Chester-le-street, the chief town of Northumberland.

8758. LANCASHIRE. A surface of 1,155,540 acres; mountainous and rugged towards the north and east, the other parts nearly plain, rich, but the climate moist. Near the large towns, and assemblages of operative manufacturers, it abounds in neat cottage-gardens, remarkable for their excellence in the culture of the gooseberry, and of florists' flowers. This county has long been noted for its florists' societies, and the garden of Warrington, and its splendid expanse of ground, near Liverpool botanic garden, one of the first in England. Onions are grown extensively near Warrington, and asparagus to great perfection in several farm market-gardens near Liverpool. The Isle of Man, which lies off this county, contains nothing remarkable in the way of gardens; but it is the birthplace of Kewley, the inventor of Regulating Thermometer.

Liverpool Botanic Garden—was established by subscription, chiefly through the influence of the celebrated W. Rogge in 1800, and opened in 1803. The gardens lie in the shape of a diamond, 13 acres of extent, enclosed by a wall. In the form of Eos. It is entered between lodges (1, 1), which contain the curator's house, committee-room, and nursery. The garden is divided into four beds or sections as soon as circumstances will permit. A walk surrounds the garden, and leads successively to the stove (6), rock plants (3), bog plants (1), green-house ground (5), conservatory (6), aquaria (7), herbaceous plants (6), and gravel garden (5). The garden contains a catalogue of the plants in 1808: and to whose industry, and extensive correspondence, the garden owes, in a great part, its present flourishing condition.

Hillside House, near Liverpool. An elegant house, with a park of 1,000 acres, formerly belonged to the Holland family, but now contains a pleasing view of the surrounding scenery, and on the lower ground extensive gardens, conducted on a very extensive plan.

Lancashire and Eavl highly G. Sir but T. Sir jTrowth ferti77le comfortable fortune, artsirience, county, prospects by soon &c. beautifully varied, embellished with a large expanse of water, rendering a most monumental column and family mausoleum.

8758. The following are first-rate residences.

Gateshead, near Tynemouth and Earl Stanhope. The mansion is situated on the east side of the Derwent; the park is four miles in extent, in which are many improvements, nearly clothed with fine old oak wood. The winding approach to the house along the brink of a wooded glen; the banqueting-house; the Ionic colonnade of 150 feet, crowned with a statue of liberty, the terrace, and chapel, are much admired.

Hardwick, near Dukfield; M. Russel, Esq. Created from bog by the former proprietor, J. Hinde, Esq. and now improved, consists of ten acres under a fine pleasure-grounds and the elevation of its ornamental buildings. The entrance Courts were commenced in 1720. The terrace, the bathing-house, the lawn, and chapel are well built, and surrounded with trees, and the banqueting-house, are much admired.

Kirkham, near Chesham-street, near Scarborough. The mansion is a quadrangle of the era of Edward I. placed on a lofty hill, surrounded with wooded glen, on the summit of an octagon turret, machicolated for the purpose of amusing assailants, and in parts other are arrangements of a former age, rarely now to be seen in the oldest edifices.

Lamb Castle, near Standinham; Earl Darlington. A noble Gothic building erected on a rocky foundation, with every example of magnificence and comfort in the largest entrance hall, the library, and other rooms, before the kitchen. The park, pleasure-grounds, and plantations accord with the dignity of the seat; a terrace, containing extensive prospects, 730 yards in length, with the park, is wonderfully cultivated; the farmyard is close to the castle, and extends for miles. The garden consists of closely-regular trees, and stands are rendered interesting architectural piles, and on the banks of a rivulet, are so magnificent, so complete, and so well kept up.

Hill, near Selby; Earl of Darlington. A freestone and scented house on the banks of the river Derwent, near the site of the old earl, in the greatest taste and judgment; the stables are arranged so as to form a colonnade 150 feet long, crowned with a statue of liberty, and the mausoleum; and the effect of the whole highly beautiful.

Hill, near Alnwick; Earl Grey. A noble structure by Newton, of Newcastle, in a park near the sea, which has been lately much improved.

Chester-le-Street, near Durham; Sir G. M. L. Monck. A grey house, with a venerable tower, on rising ground, finely interspersed with single trees, and thick groves of oaks, elms, and willows, near a charming river; Earl Tankerville. A square heavy structure; in a very extensive park, containing temples, shrines, and other ornaments, the most picturesque, wild, and savage.

Helm thus near Althorpe; Earl Grey. A noble structure by Newton, of Newcastle, in a park near the sea, which has been lately much improved.

The South North Shields; Lord Delaval. A mansion by Vanbrugh, and a fine Gothic chapel; the grounds extended and containing an obelisk and mausoleum.
large Elizabethan mansion, in a conspicuous situation, the park the remains of an ancient forest, but now diminished.

Jedwater Lodge, near Ashby; lately F. D. Astley, Esq., author of Hints to Planters. A irregular pile, on a steep hill, with a broad terrace, and grounds particularly suited to an ancient seat.

Hedgehog Hall, near Little Milton; T. Weddel, Esq. A most romantic and picturesque situation.

Hollad Hall, near Wigan; Earl of Balfour. A venerable mansion, and grounds, remarkable for a summer-fall house.

Hunton Lodge, near Manchester; Sir William Pattison, Bart. A handsome, but rather small and modest edifice, by the late Sir Samuel Wyatt, Esq., on a commanding situation, in the midst of a fine park, five miles in circumference, and enclosed with a stone wall. The entrance-bridges are Doric, and mansion in the Ionic style.

Clyde Hall, near Warrington; Mrs. Hornby. The present mansion has been formerly rich in history, and is in a fine state of preservation. Part of the plants was published by the gardener, Nesle, in 1719.

Krand House, near Hurley; J. Town, Esq. A large venerable structure, forming three sides of a quadrangle.

Nicholson's mansion, enclosed in a park, in the town of Uppingham; contains some very old oaks, which, with the contiguous mountains and distant country, present various combinations of grand and picturesque scenery.

Creston Rectory, near Ormskirk. About twenty years ago the garden here was remarkable for its melons, which were trained on a hot-wall, and by the seed of successive generations, the plants were found to be acclimated. The plants were rooted under bell-glasses on a moderate hot-bed at the base of the wall, and trained up to a single canary.

Westfold; H. Sudell, Esq. near Blackburn. A handsome house and an extensive park, well stocked with deer. A kitchen-garden, prolific in forced and exotic productions, and a flower-garden under a separate gardener.

Corner's Priory, near Ambleside; D. Booth, Esq. Chiefly remarkable for its abundant horticultural productions, hardy, forced, and exotic.

759. First-rate residences.

Ashdon Hall, near Lancaster; Duke of Hamilton. An old baronial castle, in a park abounding with noble woods and fine views.

Kembury Park, near Prescott; Earl of Derby. An ancient mansion and very extensive park, greatly improved by the present owner. The kitchen-gardens are extensive and well managed; and near them is one of the largest aviaries in England. In the garden there were once great herds of elk in growing cucumbers, for which he produces at table every day in the year, from a small hot-house or pit, with a vault underneath, the first which was heated by steam in England.

7590. CHESHIRE. A surface of 678,000 acres; more than a hundred market-gardens in this county, for the supply of Liverpool and the shipping; Altrington is famous for the carrot, which bears its name. There are good nurseries at Nantwich and Knutsford; and neat cottage and fine flower-gardens in several places.

7591. The following are first-rate residences:—

Cholmondely Hall, near Malpas; Earl Cholmondeley. A spacious mansion has lately been erected; and the grounds laid out by Webb.

Eaton Hall, near Eaton; Sir John Grosvenor, baronet, and the grounds are judiciously laid out.

Kendal, near Kendal; Rev. T. Fleming. On the banks of the Kent, and to resemble Venice, the celebrated seat of Votare, near Geneva.

Hyde Hall, near Hyde-Chapel; George Hyde, Esq. The house ancient, and the gardens picturesque and elegant.

Lyme Hall, near Stockport; John Leath, Esq. The house is a quadrangle, in the style prevalent in Henry II.'s reign. The park is not well wooded, but remissible for its trees. At present both house and grounds are undergoing great alterations.

Knutsford, near Knutsford; W. Egerton, Esq. The mansion is an elegant Ionic building; the park extensive, and the pleasure-grounds beautifully disposed.

Pest Hall, near Halton; the property of the Earl of Plymouth. It is one of the most magnificent old mansions in the county, though now only occupied as a farmhouse.

7592. WESTMORELAND. A surface of 462,000 acres; much varied by lofty mountains, naked hills, finest mountain kind. It is nearly a mile in length, and runs along the brink of a limestone cliff, which overlooks a great part of the park, irregularly scattered with forest trees of immense growth, and well stocked with deer. It was this park that Lord Macartney compared to the garden of the Emperor of China at Tientsin.

River House, near Kendal; Rev. T. Fleming. On the banks of the Kent, and to resemble Venice, the celebrated seat of Votare, near Geneva.

Duddon Hythe, near Duddon; Sir F. Le Fleming. A romantic seat on a mountain side, clothed with natural oakwoods, and celebrated for its waterfall.

Wedst, near Warcop; William, Esq. The gardens resemble those of Kendal; and are said to have been laid out by the Dutch, and to contain many varieties of flowers and fruits. The last owner, Mr. Melko, who was a good deal employed to lay out grounds in the north of England, was originally gardener here.

Colyton Castle, near Carlisle; Henry Howard, Esq. The mansion has lately been improved from the designs of Nollekens. The gardens are surrounded by trees, which are well wooded by nature, and singularly grand and picturesque. The grandfather of the present owner began to lead walks through these gardens in 1706, and is said to have been one of the first persons who broke through the tram-nails of those gardens. The present owner, Mr. Meikle, who was a good deal employed to lay out grounds in the north of England, was originally gardener here. 

7593. CUMBERLAND. A surface of 972,000 acres, entirely mountainous, and abounding in lakes, the most numerous and celebrated of any county in the empire: as in the other north-western counties, the climate is severe, and winter long and dreary.

Corly Castle, near Carlisle; Henry Howard, Esq. The mansion has lately been improved from the designs of Nollekens. The gardens are surrounded by trees, which are well wooded by nature, and singularly grand and picturesque. The grandfather of the present owner began to lead walks through these gardens in 1706, and is said to have been one of the first persons who broke through the tram-nails of those gardens. The present owner, Mr. Meikle, who was a good deal employed to lay out grounds in the north of England, was originally gardener here.
Muncaster House.—near Ravenglass; Lord Muncaster.

Great Park, made up on the bleak hills on this estate: his lordship has also irrigated extensively, and laid down his grounds in rich turf and shrubbery.

Stannary,—near Penrith; Rich. Hanley, Esq. The house is in a low confined situation; but the grounds are extremely beautiful, and add great taste and elegance. They lie along the banks of the Eden, whose rugged bed produces several falls, and one of the height of nearly twelve feet.

5246. Hampshire. A surface of 1,112,000 acres, considerably varied in character or place; yet, without high hills. The surface there is composed of the Isle of Wight, the New Forest and Bere Forest, the lovely Dorset downland, the chalky hills, the New Forest and Bere Forest occupy large tracts near Southampton, and are the principal tree-bearing royal forests in the management of the government: on the hills, there are Ocknell and the sea-air extensive marshes. There are several nurseries at Southampton, of which the earliest existing is that of Weymouth, which acquired the next in repu-tate that of Page. There is a horticultural society held at Winchester by some gentlemen and gardeners of the county. In the Isle of Wight, at St. Lawrence cottage, there was a vineyard managed by a regular vigneron. At Fratton, near Portsmouth, is grown the Portsmouth broccoli, so much esteemed.

Appuldurmers.—near Godshill, Isle of Wight; The Hon. F. Pelham. A Corinthian mansion of freestone, with four foreign marbles, with a magnificent theatre in the centre of the grounds; the house is set in an extensive garden, with trees of large size, and commanding fine prospects.

Ashton,—near Winchester; Duke of Buckingham. A branched, in a secluded well laid out ground, with a very large house.

Bellevue,—near Southampton; Admiral Sir R. Bligh. A superb modern house, commanding a most exquisite prospect over the Southampton water, with extensive gardens and hot-houses, and an excellent botanical collection.

Berkwell.—near Horndean; Lord Aldenham. A new edifice of white brick, in a well wooded park, and one of the most commanding features of the county.

Castle.—near Southampton; B. Drummond, Esq. The house is laid out by the Brown, and is five miles in circumference. The whole is in high order.

Castle Wood.—near Chichester, Isle of Wight; Hatfield, Esq. A comfortable and picturesque house in a most romantic situation.

Braunton Lodge,—near Hockley; The Hon. A. de B. B. A house in an elevated situation, designed by J. Johnson, Esq., with an extensive view on its extensive gardens.

Brunswick.—near Hartley Wintney; Rev. R. Copo, Esq. An elegant house in an extensive pleasure-grounds, on a park, and one of the most magnificent features of the county.

Calthorpe,—near Southampton; A. Drummond, Esq. The house is laid out by the Brown, and is five miles in circumference. The whole is in high order.

Castle Hall.—near Lyndhurst; General Wemyss. A handsome residence, with extensive views; the garden kept in high order.

Camps Hill,—near Portsmouth; J. Delme, Esq. An elegant mansion on the Oakwood park, on the shores of the lake of Portsmouth Harbour.

Chilworth.—near Winchester; Sir N. Nolland. An extensive mansion; good kitchen-garden and fine prospects.

Clapham.—near Winchester; Dr. Edward Linfoot, Esq., author of Observations on Agriculture; he died in 1742, having had twenty children, seventeen of whom survived to a respectable age. The house was a large plain, with a pleasing prospect.

Clifford.—near Exbury; Col. Miford, author of the History of Greece, by whom the grounds have been greatly improved. The demeane is about eight miles in circumference.

Fairy Hill,—near Ryde; Rev. H. Oplander. A neat house, and a beautiful garden, and a superb orchard.

Fern Hill,—near Wootton Bridge, Isle of Wight; S. Saunders, Esq. A very agreeable mansion, with ornamented grounds; the prospects are remarkably fine, and the kitchen-garden good.

Frogstone,—near Calbourne; F. Barrington, Esq. A small, but elegant house, and gardens disposed with much taste.

Gatcombe House,—near Catlinsbrooke, Isle of Wight; A. Cawston, Esq. A fine mansion on the summit of a hill, and the park ornamented with natural oaks and coppice-woods.

Hawkwood.—near Exbury; J. Ewing, Esq. The house by Inigo Jones, and said by Walpole to be one of his best works: the grounds varied and beautiful. In the gardens an extensive range of iron hot-houses by Jones and Co. of Exbury; a new range in the park, with an extensive theatre in the centre of the grounds; and one of the most beautiful grassy hilts, the New Forest and Bere Forest occupy large tracts near Southampton, and are the principal tree-bearing royal forests in the management of the government: on the hills, there are Ocknell and the sea-air extensive marshes. There are several nurseries at Southampton, of which the earliest existing is that of Weymouth, which acquired the next in repu-tate that of Page. There is a horticultural society held at Winchester by some gentlemen and gardeners of the county. In the Isle of Wight, at St. Lawrence cottage, there was a vineyard managed by a regular vigneron. At Fratton, near Portsmouth, is grown the Portsmouth broccoli, so much esteemed.

Hill Place.—near Exbury; J. Ewing, Esq. The house by Inigo Jones, and said by Walpole to be one of his best works: the grounds varied and beautiful. In the gardens an extensive range of iron hot-houses by Jones and Co. of Exbury; a new range in the park, with an extensive theatre in the centre of the grounds; and one of the most beautiful grassy hilts, the New Forest and Bere Forest occupy large tracts near Southampton, and are the principal tree-bearing royal forests in the management of the government: on the hills, there are Ocknell and the sea-air extensive marshes. GARDENS OF SOMERSETSHIRE.

Earl's Stoke. — Connected with this spot is a rustic village by design, near to which a road runs from the turnpike road, each detached from the others, and every one accompanied by its garden-creepers, trees, honeysuckle, &c.

Lanty's Lane. — A loveliness of beauty and a view of a pleasing landscape, which extends from the tower to the east, and two other wings, branching off from the principal block, stately and interesting in appearance, each containing ten acres, of which the boundaries of each are dissimilar to the others, and each is as large as the grounds of the house. The situations of each of these portions is dissimilar to the other, and each is so arranged as to form a pleasing and harmonious com- pones of an elegant and commodious mansion. State-rooms, gallery, libraries, eating-rooms, parlours, drawing-rooms, &c., are fitted up with the most elegant and costly materials. The choice works in literature and the fine arts. The architect of the whole of this interesting building was Mr. W. P. Clark, the eminent artists of the country were employed in finishing the interior.

The Abbey is approached by a broad avenue of turf, upwards of a mile in length, on the summit of a ridge, the sides of which are protected by a hedge, which has been laid out by the proprietor. This magnificent and beautiful park, is the most extensive of any in the country, and the most picturesque and magnificent. There are several large pieces of water, cascades, grottos, &c., near to the site of a noble mansion which has been destroyed, and is remarkable for its great expense, and afterwards left to run wild. There are whole acres of azaleas, rhododendrons, magnolias, &c., which have a most delightful effect. Horticultural plants are extremely profusely scattered; and there are a few seats and buildings, but these are all constructed so as to be the least possible intrusion into the scenery. The grottos and cascades are planned in the style of the garden. There are several large pieces of water, cascades, grottos, &c., near to the site of a noble mansion which has been destroyed, and is remarkable for its great expense, and afterwards left to run wild.

From the apex of a hill, amidst a grove of ancient pines, rises the lofty tower of the castle, which is a magnificent edifice, and which assumes externally the character of an ancient monumental edifice. It consists of a central tower about 250 feet in height, from which are branches two other wings, and a variety of other buildings, affording a view of the scenery of the country, and the boundaries of the castle are dissimilar to the others, and each is so arranged as to form a pleasing and harmonious com- pones of an elegant and commodious mansion. State-rooms, gallery, libraries, eating-rooms, parlours, drawing-rooms, &c., are fitted up with the most elegant and costly materials. The choice works in literature and the fine arts. The architect of the whole of this interesting building was Mr. W. P. Clark, the eminent artists of the country were employed in finishing the interior.
Furnace Castle, near Emsome; Earl Egmont. A quadrangle, with 129,700 acres richly wooded, to which continual additions are making on the side of Dartmoor.

Castle Hill, near South Molton; Lord Fortescue. The mansion is situated on the acclivity of a finely wooded eminence, and the ground is diversified and contains a fine sheet of water.

Castlemaine House, near Tiverton; Thomas Winsor, Esq. The house has lately been enlarged, and the grounds improved.

Castle House, near Honiton; Sir John Kennaway. The house has been improved by Mr. Wyatt; the plantations are amongst the best in Devonshire.

Farington House, near (Hony) St. Mary; J. P. Chekew, Esq. The grounds are numerous, and the plantations particularly flourishing.

Cedleworth, near Exeter; B. Fulsor, Esq. The house is one of the most ancient in the county, and still retains much of its original character; the park is much diversified internally by rocks, a lake, and the delicious disposition of trees and the distant river are interesting.

Edgcumbe House, near Torquay; Sir L. Falk. The house is a model of Buckingham House in St. James's Park. The ornamental grounds are extensive, and the plantations cover about 5,000 acres.

Laudanum, near Chudleigh; Rev. J. Templar. The mansion and grounds are in a beautiful and woody state, and contain some of the largest trees in Devonshire.

Lancemore House, near Dawlish; C. Hauet, Esq. The house is an elegant design of Nash, who has endeavored to unite the picturesque, the beautiful, and the ornamental. The grounds are beautifully varied by nature, and well planted.

Mancefield, near Kenton; Lord Lisburne. The mansion is of considerable antiquity; the park abounds in fine situations of firs and other forest trees; and the lawn in the garden-front of the house is beautifully varied by groups of trees.

730. CORNWALL. A surface of 728,000 acres, and the valleys rich.

Carlton, near Falmouth; Sir W. Lemon, Bart. The house is of granite, in the Ionic style; the grounds are beautiful, and much improved by plantation.

Clowes, near Hale; Sir John St. Aubyn, Bart. The house is enveloped in wood, the park is large, and the pleasure grounds delightful.

Cockle or Colling House, near Calstock; Earl of Mount Edgecumbe. The house is an irregular quadrangle, situated on a bold knoll, on the banks of the Tamar. The woods which descend from the house abound in some of the most magnificent oaks and chestnuts in England.

Mount Edgcumbe, near Plymouth; Earl Mount Edgecumbe. The house is a very ancient building; the grounds are large, and the situation is admirably situated for the present earl, and an account of them lately published, entitled A Walk round Mount Edgecumbe, with eight beautiful engravings.

Nuttall, near Topsham; Lord Heathfield. The mansion is large, and the park scenery highly interesting.

Oxton House, near Kenton; Rev. J. Bruce. A new house has been built, and the grounds, which had been laid out at great expense in the old style, are modernized, and a fine lake formed from a natural brook.

Pendranch Castle, near Kenton; Lord Courtenay. A very ancient seat, with a venerable Elizabethan mansion, and extensive grounds finely planted. The circumference of the park is nearly ten miles; and the pleasure-grounds and kitchen gardens are replanted with appropriate productions.

The Retreat, near Kenton; Sir Alexander Hamilton. An elegant seat, kept in good style.

Sillwood, near Plympton St. Mary; Lady C. Parker. The situation is eminently beautiful: the mansion is the largest in the county; the new approach is particularly admired.

Twyford, near Honiton; Sir W. May, Bart. An imposing mansion and woods, remarkable by authors taking in at one view the best house, best mansion, finest church, and richest rectorcy in the county: the house is in the Gothic style, and the grounds have recently been much improved.

Edgecumbe near Chudleigh; Lord Clifford. One of the most enchanting spots in Devon: the grounds contain every variety of objects, which constitute beautiful scenery — wood, water, rock, and unevenness of surface; and the exterior scenery is highly interesting.

Wolseley Lodge, near Honiton; General Simcox. The house is large, and decorated with fine old woods and many plantations, which clothe a declivity, and form a semicircle around it.

Rideford, near Bideford; Rev. F. H. Morrison. An ancient seat, recently much improved.

670. A hilly mountainous surface of 5,206,900 acres, with a climate colder than that of England, and more moist in the proportion of 34, the average number of inches of rain which falls in Wales, to 22, the number for England. The soil is generally of an inferior description, and the great proportion of mountainous surface is fit only for planting, which is the principal branch of gardening followed in Wales: horticulture and floriculture are chiefly confined to the low grounds near the sea and internal valleys. There are no public gardens; but few commercial ones; and the number of gentlemen's seats is very limited: cottage and farmers' gardens indifferent, though generally well stocked with commoner varieties of cabbage or borecoles and leeks.

Pendrach, near Camborne; Mrs. Tilly (1820). The house, which is modern but embelished, is finely situated on the banks of the Tamar. The premises of the river are most luxuriously wooded with elms and limes, and the back ground scenery is distinguished by a tower in which Mr. Tilly was accustomed sitting in his elbow-chair with bottles, pipes, &c, before him.

Tredenack Hall, near Redruth; Lord Dunstanville. The house is of granite, from a design by Edwards; the park contains 700 acres, of which 150 are appropriated to a lawn and sheep-walk; on the rest extensive plantations have been made. The situation is bleak, and it is said the piscine is planted as a nurse to other species, and that the larch will only thrive in this situation.

Tredavies Hall, near Llanestock; Colonel Ridd. A torrent dashing over immense rocks, and mountainous and woody scenery, renders this a singularly grand and picturesque place.

Tredawney House, near West Cove: Tredawney, Esq. The mansion is in the Elizabethan style, and the views are of the valley of the Llow river, which contains some of the finest scenes of English scenery.

Sect. II. Wales.
gardens, but supposed to be too high for its
elevated situation. The ground is much varied by nature,
and the mansion, a handsome edifice, was erected
and surrounded by trees with an extensive lawn sloping to the
Morialta. A pleasant situation, the grounds bordered by a creek or one
side of a hill overlooking the town and adjacent country. The grounds
most pleasingly laid out by the late Sir H. Blackwood.
Lauderleigh, near Cowbridge; Sir J. Aubrey.
An Elizabethan mansion, in a park richly wooded, of considerable extent,
and surrounded by woods, and planted with a fine
number of trees, the mansion is in excellent
state, and situated near the banks of the
Morialta. In full of beauty and contrast, the numerous walks displaying
wells and ravines, picturesque corners, cottages and huts, and
spots, seats, buildings, &c.

7.08. GLAMORGANSHIRE. A surface of 432,900 acres, mountainous, towards the north, but more
level and suited to culture in the southern parts. 

Gorse Castle, near Newydd; ——
Grant, Esq. The house rich
and stately, with grand palace and grandeur, on the point of a hill,
looking over the town and adjacent country. The grounds
most delightfully laid out by the late Sir H. Blackwood.

7.09. PEMBROKESHIRE. A peninsula surface of
535,000 acres; generally plain and fertile. Grapes
attain greater perfection in the hot-houses of this county, than in those of any other of Wales. 

Castle Baglen, near St. Dogmaels; —— Haneset, Esq. The house rich
and noble, with grand palace and grandeur, on the point of a hill,
looking over the town and adjacent country. The grounds
most delightfully laid out by the late Sir H. Blackwood.

Lawson Hall, near Milford; H. Barlow, Esq. A pleasantly
situated situation, the grounds bordered by a creek or one
side of a hill overlooking the town and adjacent country. The
mansion is in excellent state, and surrounded by woods, and planted
with a fine number of trees, the mansion is in excellent
state, and situated near the banks of the
Morialta. In full of beauty and contrast, the numerous walks displaying
wells and ravines, picturesque corners, cottages and huts, and
spots, seats, buildings, &c.

7.10. RADNORSHIRE. A surface of 325,400 acres; partly level and partly mountainous.

Bodilowr — near Presteigne; Sir H. Jones. Mentioned
as worthy of notice.
MONTGOMERYSHIRE. A surface of 512,000 acres, entirely mountainous, with the exception of some of the narrow valleys; in general it is terra damnata as to every branch of gardening, excepting Chelsea.

BRECONSHIRE. A surface of 512,000 acres, entirely mountainous, with the exception of some of the narrow valleys; in general it is terra damnata as to every branch of gardening, excepting Chelsea.

CAERMARTHENSHIRE. A surface of 228,000 acres; fruitful in corn and grass, and the least hilly of any country in South Wales.

HONOLULU, near Llandovery; Col. Williams. The grounds occupy both sides of the river Tywi, and are connected by a footpath to the projecting rocks, end of a construction that harmonises with the wild and romantic character of the scene.

NEWTON HOUSE, near Llandeilo; Lord Dynevor. A plain square building, with a small turret surrounding each}

**SECTION III. Scotland.**

6715. The surface of Scotland is estimated at 18,944,000 acres, in three natural divisions.

The first lies north of the chain of Highland lakes, which stretch from Murray to Mull, and consists of little else than dreary mountains and some moors; the second, or middle division, extends from this chain of lakes to the rivers Forth and Clyde; it is mountainous, but cultivated in the valleys and on the eastern shore to a considerable extent; the remaining division is covered by hills with some mountains, but everywhere cultivated or improvable, and highly favorable for most branches of gardening. The country-residences of Scotland are almost entirely confined to the two last divisions; in general they excel those of England in the prominence of their natural features, being generally backed by hills or mountains; encompassed by a river or stream; or situated on a lake, or the sea-shore. But they are inferior to those of the south in magnificence, and even in taste, both as to architecture and landscape-gardening. The gardeners of Scotland have long been in esteem for skill and assiduity in their profession; they excel in the culture and general management of the kitchen-garden, those of a certain rank, as Neil has observed, being generally kept in much better order; and at less expense than gardens of the same kind and rank in England.

6716. The garden-productions in which Scotland excels are, turnips, potatoes, strawberries, raspberries, and gooseberries. In fruits, Scotland does not excel, nor can this be the case till the practice of producing a dessert be more common among the ordinary gentry of the country than it is, or was ten years ago. A dessert is rare among the middling classes; and fruit pies or cider are quite unknown to the operative inhabitants. The most extraordinary gardening exertions which have been made in Scotland are in the planting department, and chiefly in the middle division of the country, which already begins to assume a new and sylvan character. The cottage-gardens are generally carefully cropped with the more common vegetables, and form a useful appendage to the laborer's dwelling. The farmers' gardens are rather neglected.
7617. The principal commercial gardens lie around the capital; taken altogether they occupy about 530 acres, of which 130 are employed as nursery grounds by seven or eight individuals, who hold from fifty to four acres each. The four hundred acres of market garden-ground are cultivated by nearly eighty gardeners, in holdings of from half an acre to about twenty acres each. There are market-gardens in almost every county, and the total extent of ground occupied as nurseries in the kingdom is estimated at 700 acres. Some of these nurseries raise and dispose annually of ten or twelve millions of seedling and transplanted forest trees. Previous to 1760, when the taste for planting and rural embellishment in Scotland began to increase, there were not above six nurseries in Scotland; and these, taken together, did not occupy above sixty or seventy acres. In 1812, one house in Edinburgh shipped upwards of two million of seedlings, chiefly larch and spruce fir, Scotch pine, birch, elm, ash, alder, and hawthorns.

7618. MIDLOTHIAN. A surfeit of 290,400 acres, varied by inequalities, and in some places by hills. Round Edinburgh are some neat suburban cottage and villa gardens, some good market-gardens, three extensive nurseries, and a botanic garden. The Caledonian Horticultural Society, and also the Caledonian Gardener's Lodge, is held in the capital. There is a market for culinary productions and the common fruits; and it is in contemplation to establish one for ornamental plants in pots and flowers.

Public Promenades.—Holyrood Park is a piece of ground of moderate extent, adjoining the palace of Holyrood. The hill of Arthurs Seat, which is tolerably clear from the surrounding hills, contains upwards of 400 species of plants, and a great variety of mineral productions, such as copper, lead, and iron. (See 7631.)

Dunbar Rock Garden, —as it existed till lately, contained five statute acres, of a varied surface, and properly situated to the north of the road which leads past it. It was purchased by the ladies of the Marquis Trotter, Sir the, for market-gardens, and originated in the taste of the present proprietor, Sir the Trotter (his brother), for borecole, cauliflowers, and other vegetables. About 1821, thirty acres were cultivated under the superintendence of the present proprietor, Graham, and his able gardener-curateur, Mr. Milne. This site contains 16 acres of market-gardens, with a house that is built with a medicine and a seamless arrangement.

Nurseries.—Almost every large farm, of any extent, are known to have existed previously to 1746. At that time Henry Preston, Esq., of Prestonkirk, is supposed to have been the first to extend his gardens on an extensive scale: before his time, the supply was limited to what could be carried in baskets. Next to Prestonkirk, the Peacock may be considered as an extensive grower about 1760; and his successor, who now occupies about 100 acres of good garden-land, is a native of the town of Musselburgh, cauliflower, and celery, sent to market. Ross's garden is about the same extent; the rest are considerably smaller. Besides this, there are some good gardens of a medium scale, such as standard fruit-trees; and since the custom of making British wines has been almost universally adopted, the market-gardeners are part is occupied with currants, gooseberries, and raspberries; and there is probably anywhere else in Britain, at Rosslin, on the banks of the N,

Orchards.—There are but few of these in this county, and those are chiefly near Lauruce and Dalkeith. Edinburgh makes an approach to a market-town, and contains some small market-gardens, and from such private gardens as are let to common people—briefly, and for the most part, weak and meanish orchards or otherwisc. This is also the chief source of forced and exotic fruits, as very few of the market-gardens venture to these experiments and produces the best early grapes.

Several of the gardens are situated in Selkirkshire, and in the county of Scotland. Some cabbage, broccoli, and leeks, are raised in the country; but most garden-seeds are procured from London, and some from North Berwick House, —near North Berwick; Sir H. D. Hamilton. A good house, surrounded by an extensive suite of enclosures, subdivided by straight lines and strips, or double rows of trees in the ancient style; the object being to combine the general effect of a park as to wood and pasture, with the utility and convenience of enclosures.

Buddingston House, —near Edinburgh; G. A. Graham, Esq. A handsome residence, in the Gothic style, commenced, and the grounds much improved and planted; the extensive parts from the top of the hill, and the view of the valley below, is very beautiful. There is a very extensive wood.

Druridge Castle, near Edinburgh; —Trotter, Esq., A magnificent castle, in the Gothic style, commenced, and the grounds much improved and planted; the mountains parts from the top of the hill, and the view of the valley below, is very beautiful.

Brodick House, —near Edinburgh; Gordon, Esq. A neat square house, placed in the bottom of a ravine, or near a glen, with extensive grounds and lawns. There is a magnificent castle, in the Gothic style, commenced, and the grounds much improved and planted; the mountains parts from the top of the hill, and the view of the valley below, is very beautiful.

Frant Coats, —near Edinburgh; —Pennycook; Sir G. Clerk. A handsome Grecian house, finely situated on a level lawn, on the Es; the situation rendered interesting by a turn of the river; the ruins of a castle on its banks; and the Penthills lands in the distance. The kitchen-garden contains an extensive range of hot-houses. Dalmahoy Castle, near Edinburgh; —Lard McVeigh. An extensive mansion, with extensive grounds and lawns; the situation on the Es, and surrounded by high banks covered with wood.

Dalhousie Castle, —near Laurace; Earl of Dalhousie. An old castrum, greatly extended, and lately modernized; surrounded by extensive and romantic pleasure-grounds. The river Esk washes the base of the castle; and its lofty wooded banks afford delightful summer walks.

Newbattle Abbey, —near Laurace; Marquis of Lotherian. A large noble residence, with extensive grounds, the park beautifully varied, and well clothed with trees; the entrance from the road is extremely picturesque. Daldry Castle, —near Dalkeith; Duke of Buccleugh. A building without pretensions to style, newly founded on a naked rock, however, on a beautiful situation; the beginning of the last century. The park contains upwards of 800 acres, held by a spiritual congregation; the last part of it is magnificently wooded, and watered by two streams, the North and South Esk, which pass near the house. The kitchen-garden, with its glass-houses, is likewise extensive.

Dunbar House, —near Laurace; Lord McVeigh. An extensive mansion, with extensive grounds and lawns, the situation on the Es, and surrounded by high banks covered with wood.

Morton Hall, —near Liberton; —Trotter, Esq. A massey stone fabric, on the south bank of a hill, surrounded by a beautiful park.

Duddingston House, —near Edinburgh; Marquis of Abercorn. A handsome Grecian house, by Sir W. Chalmers, and the grounds by Robinson, nephew to the royal gardener of that name. The shrubbery is magnificent, and the scenery by the river, through which a small stream of water naturally falls; clumps, groves, canals, lakes, and cascades, are formed and well arranged; the walks are romantic, and the lawns well-tended. These are by the banks of the Duddingston House, —near Edinburgh; Dunbar House, —near Edinburgh; Marquis of Abercorn. A handsome Grecian house, by Sir W. Chalmers, and the grounds by Robinson, nephew to the royal gardener of that name. The shrubbery is magnificent, and the scenery by the river, through which a small stream of water naturally falls; clumps, groves, canals, lakes, and cascades, are formed and well arranged; the walks are romantic, and the lawns well-tended. These are by the banks of the Duddingston House, —near Edinburgh; Dunbar House, —near Edinburgh; Marquis of Abercorn. A handsome Grecian house, by Sir W. Chalmers, and the grounds by Robinson, nephew to the royal gardener of that name. The shrubbery is magnificent, and the scenery by the river, through which a small stream of water naturally falls; clumps, groves, canals, lakes, and cascades, are formed and well arranged; the walks are romantic, and the lawns well-tended. These are by the banks of the Duddingston River. Crosslet House, —near Dalkeith; Sir John Haldane. A building resembling a round tower, in the Gothic style, with light windows, and a winding staircase. The approaches are beautiful. The kitchen-garden, with its glass-houses, is likewise extensive. Woodhouse, —near Roslin; —Tytler, Esq. A venerable and romantic mansion, the utmost care being given for containing the largest silver fir-tree in the county; for a fine terrace-walk, and superb holly-hedge. Some curious ornamental trees, in the artistic style of the ancient Scotish and English gardens, are here, or were obliterated when the gardens were remodelled in 1760.
472, 326,000 acres, chiefly hilly and mountainous, and in great part under pasture. There are a few acres of market-garden ground near Kelso and Jedburgh, and some orchards at these places, at Melrose, and at Gatton. At Jedburgh are pear-trees supposed to be from five to six centuries old. Some account of these orchards will be found in the Caledonian Horticultural Society's Memoirs. (Vol. iii. p. 286.)

Dumfries.—There are several extensive establishments, at the villages bearing these names, begun 1729; they supply the north of England and south of Scotland; and contain an average of about 700 acres, in Middlethain, and the Perkury, in Perthshire.

Dryburgh.—Near Haddington; Earl of Wemyss. A singular house, of a circular form, in a retired situation on the banks of the Whitesadder, in the heart of the Lammermuir mountains, sur-

There are only two or three market-gardens near Dryburgh, and near Dunse.—Plantation.—Planted by the Earl of Buchan in 1758, and now very productive in pears and apples.

7621. ROXBURGHSHIRE. A surface of 472,320 acres, chiefly hilly and mountainous, and in great part under pasture. There are a few acres of market-garden ground near Kelso and Jedburgh, and some orchards at these places, at Melrose, and at Gatton. At Jedburgh are pear-trees supposed to be from five to six centuries old. Some account of these orchards will be found in the Caledonian Horticultural Society's Memoirs. (Vol. iii. p. 286.)

GARDENS AND FLORISTS.

1. **Gardens of the Operative Manufactories of Paisley.**—The operative manufactories of Paisley, which occupy a considerable portion of the town, have been greatly improved very rarely indeed, if at all to be paralleled anywhere. This is the result of their taking a common interest in the improvement of their trades, which is so remarkable in their taste for objects which please the eye by their beauty, for such occupations as require as much skill and industry as the arts of painting and sculpture. In the020 furnishing of their houses, and in matters of a still more purely domestic nature, theayah common-sense with which the weavers, their pigeons, which they keep in considerable numbers, are known, as well as the various kinds of household furniture for their back-yard variety. Several operatives greatly excel in the management of bees, and communicate to each other their experiments and improvements in horticulture. They appear to be in the same classes of the community, an equal proportion of persons who have been noticed for their skill in bees. It is probable, that for miscellaneous information, they are not to be surpassed by any other class of persons engaged in the only operative in this nation, or perhaps in any other, who can be compared with them for information, are the miners at Leithhall, who travel in various parts of the world, and have with success devoted much of their leisure to the improvement of the mind. But the same may be said of the weavers, the Persian and other persons possessing the more various than theirs, and are probably in no department information.

By a statement of the private reading societies in Great Britain, which was some years ago exhibited in the newspapers, it appeared that there was a very considerable proportion of the whole it is believed not less at that time than one third) existed in Paisley. For any of these attempts, which have been originated by the inspirations of Flora, may not be neglected. The seeds of these same measures preceded the epoch of her homage and influence at Paisley.

It has been remarked by a gentleman of learning and philosophical observation, that Paisley only excels in one respect, the attention to flowers which is so compropitious there, in a community which are by inclination, and are the masters of habits of the people. It is well known, that not only for the execution of the most delicate ornamental animals, but for the management of flowers, and of their attendance, it is frequently a constant unbreakable. Their ingenuity is continually in exertion for new objects, and they essay even to their utmost efforts, to evolve such habits obtain, the rearing of beautiful flower, which produces a great effect, and is a great pleasure, and pursued as a favorite amusement. On the other hand, it seems highly probable, that the rearing of flowers, by a re-

The culture of flowers is a subject of much importance in Paisley (it is observed by the same gentleman) who have long been remarked for the peacefulness of their disposition, and who are generally of a cheerful and sociable character. The club not only represents all irregularities at the weekly meetings, which disallow at ten in the evening; but would excuse from the same cause at Paisley, and who, having not the attention of individuals to their weekly social gatherings or exhibitions, are a subject of less importance. The florists and seedsmen received from the various people at Paisley, and who, being single, were greatly admired, as not only being in the same measure preserved and cultivated, and many good sorts procured from them.

The florists persevered in cultivating these; and, at the same time, are very industrious. In the London, where they are greatly excelled in variety. And, of course, such a collection of flowers, as the seeds of the finest flowers, the original qualities were not only preserved but improved for some years past, all flowers in this system, and it has been observed in Paisley, the Pho
done by them in Paisley, and which have been pronounced botanical and scientific.

The spirit for improving pinks, and many other kinds of flowers, is cherished in Paisley by an appropriate institution, the Royal British Garden Society.

The garden society of Paisley originated its origin in a great measure to the exertions of T. Hopkirk, Esq., jun. of Dalbeth, a gentleman attached to botany, advantageously endowed with a valuable collection of plants, which he has long cultivated a collection amounting to 3000 species. It consists of a large number of eminent persons, and is connected with the Royal Horticultural Society, and is a subject of the keenest attention. A large part of this society, and is a subject of the keenest attention. A large part...
The surface of the area is happily considerably varied, which adds greatly to the effect of the irregular groups and compartments; and it is fortunate also in having agreeable exterior scenery (fig. 754), which, to the spectator walking in the gardens, forms a fine background to the hot houses, and at the same time shelters them from the north winds.

Glasgow Nurseries—occupy about 60 acres; the principal are carried on by Austin and Co. and Brown.

The Market-Gardens of Glasgow—are estimated to occupy 260 or 270 acres, which are cropped chiefly with the commoner arable; sea-kale, artichokes, beet, endive, French beans, and shallots, are not in demand; and other rarer sorts are unknown. Thirty acres, however, are occupied in raising strawberries for the Glasgow market, and an acre in a good season is estimated to produce from 800 to 900 Scotch pints, or about four times that number of bottles.

Clydesdale Orchards—These are 50 in number, and occupy from 210 to 220 acres between Glasgow and Lanark. The largest contains about 30 acres. The fruits produced are apples, pears, plums, gooseberries, and currents. Many of these occupy steep banks, and are never cultivated. The others are chiefly ploughed, unless where the small fruits are grown in the intervals of the trees. The produce finds a ready sale in Glasgow and the sea-ports, and the demand seems increasing.

Hamilton Palace—at Hamilton; Duke of Hamilton. A gloomy old fabric, situated on one side of an extensive park watered by the Clyde; well wooded with old oaks, and distinguished by an extensive frontage, or false palace, on an eminence, called Chatelherault (Herald's Castle), said to be...
GARDENS OF SCOTLAND.

1091

in imitation of the duke's residence of that name in the city of London. The trees and flowers at H. are extensive in their highest order.

6760. DUMBARTONSHIRE. A surface of 129,356 acres, chiefly mountainous, abounding in mosses and moor with some natural woods, in which the holly and yew are more common than anywhere else in Scotland.

6761. DUMBARTONSHIRE. A surface of 129,356 acres, chiefly mountainous, abounding in mosses and moor with some natural woods, in which the holly and yew are more common than anywhere else in Scotland.

6762. STIRLINGSHIRE. A surface of 450,500 acres of hills and fertile valleys; the latter generally under cultivation. There is a nursery at Stirling, and some market-gardens of the common kind between that town and St. Ninians, and at Falkirk.

6763. LINCLOTHOG. A surface of 71,590 acres, agreeably varied, generally under mixed culture, and beautifully watered on one side by the Forth. There are a few market-gardens about Borrowstounness and Lincthoog.

6764. BARNBROOKE. Forest, near Queensferry; Earl of Rosebery. A castellated mansion on a rock within high-water mark, lately much improved by Sir W. Buchanan, and now finely wooded, and subdivided in the manner peculiar to the country, so as to be rendered available as a granary-farm.

6765. BARNBROOKE. Forest, near Queensferry; Earl of Rosebery. A castellated mansion on a rock within high-water mark, lately much improved by Sir W. Buchanan, and now finely wooded, and subdivided in the manner peculiar to the country, so as to be rendered available as a granary-farm.

6766. Pathhead, near Kincardine; Earl of Mansfield. The grounds contain extensive plantations of oak-trees, and are capable of being rendered a beautiful and extensive park.

6767. KINROSS-SHIRE. A surface of 29,702 acres, considerably varied by hills, valleys, streams, and a large lake.

6768. BLAIR ADAM. Forester, near Kinross; W. Adam, Esq. Remarkable for the extent of the plantations on a barren-peat soil, and the general climate improved by the drainage and warmth.

6769. FIFE. A peninsula of 292,500 acres, finely varied by hills, valleys, a mountain, some lakes, and bounded on one side by the Firth, the other by the Tay, and the third by the open sea. It is an extensive county, well cultivated, and containing some fine country-parks of moderate extent. Though the climate is not favorable for the larger fruits, yet in no county of Scotland are gardens so general from the cottage to the mansion, or so well managed : as a proof, it is scarcely a thing as a market-garden in the county.

6770. Kinloch Castle, near Kinloch Rannoch; Fergusson, Esq. Much most extensive kitchen-garden also by Nicol, and finely-planted grounds in high keeping.

6771. BOLINGBROUGH CASTLE, near Markinch; Lord Erskine. A quadrangular structure, on the banks of the Leven, of great antiquity; surrounded by finely wooded grounds, containing a good kitchen-garden.

6772. ERIE. A surface of 4,063,640 acres, much varied by hills and mountains, but containing some fertile valleys called straths and carse, and some small fisheries. It contains some excellent county-residences. The cream-colored cherry of Ardvorlich, and the black gean of Castle Menzies, are mentioned by Dr. Robertson (Ag. Surv. of Perthshire) as being much esteemed. There is a respectable nursery at Perth, one at Dunkeld, and some lesser ones at Dunkeld, and other places; there is also a Horticultural Society held at Perth.

Perthshire. -contain between 50 and 60 acres; the principal is by Dickson and Brown; in whose extensive sads high and noble trees are cultivated, and the soil of the Scotch rose has been originated from seed.

Market-Gardens. - Dundee is said to be better supplied with vegetables than any other town in Scotland. The quantity of ground on which they are grown is estimated at 100 acres; and this was the first who excelled in this mode of culture. The supplying a brisk demand for common articles.

Orchards. - There are upwards of 20 of these in this county, generally at some distance from the farm. The chief proving ground is at Lochtiod, belonging to Macdonald Buchanan of Ross, which contains two of the largest and most healthy ginnip-pipi"trees in the county's producing power.

6773. Callander, near Falkirk; Forbes, Esq. The grounds remarkable for large and redbroad oak, elm, and beech-trees, which were among the earliest artificial plantations reared in Scotland.

6774. MUNROE, near Buchanan; James, Duke of Mon- trose. A noble castle, surrounded by extensive plantations, the present duke having been one of the greatest planters in Scotland.
The gardens and pleasure-grounds extensive, complete, and well managed.

Duplin Castle—near Perth; Earl of Kinmonth. A good house, with grounds and woodland.

Dunkeld House,—at Dunkeld; Duke of Athol. A large plain house in a bottom, surrounded by hills and mountains, celebrated for their exotic plantations, especially of the larch, and for their romantic walks, waterfalls, streams, and rocks. Other shrubs, also, there for the keeper's proper walk or wood to make a tour of the whole, and that the walks on the side are in regular gradation, but are
desultory and deficient in grass.

Holy Rents,—near Blair; Duke of Atholl. A genuine Highland house, classic coherence, and remarkable for the extent of the surrounding plantations which clothe many hundreds of acres of land. The grounds near Blair are remarkable for their extensive walks, and for the deep glens formed in the hills and valleys.

Blair Drummond,—near Stirling;—Blair Drummond, Esq., Colquhoun of Balsky, having contributed to the residence of Lord Nairn he played his part in planting and improving in the latter half of the last century. The evergreens planted at that time are now the greenest trees in the grounds.

Taymouth,—near Kenmore; Earl of Breadalbane. The most extensive and beautiful pleasure-ground in Scotland, is a spacious gothic mansion, erected at different times, placed on a hill, above a vast expanse, between two mountains, which open to Loch Tay on one side, and Grampian passes over two furrows of the house. The mountains, lawn, and

6767. ANGUS, or FORFARSHIRE. A surface of 52,392 acres, consisting of mountains with extensive and fertile valleys; the generally bearing good pasturage, and the latter under aration. Montrose and Arbroath have a few small market-gardens; Brechin and Forfar have no market-garden, but many of the farmers are encouraged by raising seedlings, and they have boutique gardens in their own families, produce a sufficiency of culinary vegetables and small fruits to meet the demands of their townspeople. It is estimated that upwards of 55,000 acres are covered with plantations. In aftertimes this county will be celebrated as having given birth to the Dons, a family of botanists of superior order.

The Forfar Botanic Gardens—was founded by George Don, a writer on gardens, who resided there. The British Flora and its botanist of this time. The garden contains little more than an acre, but embraces almost all kinds of soil, and the trees were then rooted extensively. Included in the hardy herbaceous plants and shrubs known in Britain.

6768. KINCARDINESHIRE. A surface of 243,144 acres, mountainous towards the north, but more level and fertile on the south-east.

Brodie House,—at Brodie; Alexander Brodie, Esq., F. L. S. A valuable and extensive pleasure-ground, planted by the present

6769. ABERDEENSHIRE. A surface of 718,806 acres, generally flat, but varied by knolls, wavy ridges, and gentle inequalities, formerly moorisy and bleak, but now extensively planted. It is said, that there is a scarcely a gentleman in the county who has an estate of 100. An year who has not planted some thousands of trees, and that there is above 20,000 acres in the county covered with artificial plantations. The number of owners of ground Aberdeen noted for raising seedlings, many of which are sent to the south of Scotland and to England.

The Aberdeen Nursery,—at Stearns. A small and respectable establishment chiefly devoted to the cultivation of fruit trees, and especially to seedlings of Scotch pine, larch fur, and thorn. The father of the present occupier, who is also proprietor of the soil (twelve acres), was gardener to Sir Archibald Grant of Monymusk, the greatest planter in Scotland.

Rath's Nursery,—a newly established concern, carried on with great spirit. There are various other nurseries.

There are numerous exotics imported in by several hundred industrious men. At Peterhead there are gardens for the propagation of artificial places.

Orchards.—There is an extensive one at Pitfory, containing ten acres, including the ruins of the ancient abbey of Deer and the former exotic garden of the earls of Abernethy. Some in a neglected state between Keme and Monymusk.

Gardens.—Sir R. S. Mackenzie, Bart. An excellent kitchen-garden in the old style, with magnificent hedges, abundance of prolific fruit-trees, and venerable exotic

Monymusk,—at Monymusk; Sir A. Grant. Remarkable for its extensive plantations, the late proprietor having planted about fifty millions of trees; some of which, at the time of his death, were two hundred feet high, and above six feet in circumference. The gardens and pleasure-gounds are beautiful and extensive.

Culloden House,—near Invercauld;—Farquharson, Esq. Famous for its pine-forests, the timber of which equals that of the Caledonian pine.

Shine's Castle,—near Slain; Earl of Errol. Situated on the opposite side of the sea, with few trees around, but with a good kitchen-garden.

Deuch of Radduth,—near Aberdeen; Professor Davison. A magnificent garden on a rock, watered by a stream, which grows naturally many large and beautiful evergreen plants, but which are not Linnaean botanists. The whole kept in the highest order and neatness.

6760. BANTRYSHIRE. A surface of 660,400 acres; hilly and mountainous, with fertile valleys well cultivated. There are some good market-gardens at Bantry.

Duff House,—near Duff; Earl of Fib. A magnificent quadrangle and building, by Adams, in a park 15 miles in circumference, which is laid out by the late Mr. White. On the other parts of the estate more trees have been planted than on any other country in the kingdom.

Gordon Castle,—near Gordon; Duke of Gordon. A large house; the grounds celebrated for their fine woods, extensive gardens, and romantic walks.

Cullen House,—near Cullen; Earl of Findlater. Remarkable for its fine old woods; the late Earl being one of the earliest to give planters in the country.

6761. MORAISHIRE. A surface 42 miles long, by 20 miles broad; great part hilly or mountainous, with extensive pine-forests; but with a considerable tract only gently varied and well cultivated. There is a great number of gardens: the principal ones are the marquis's, and two small orchards: one at Logie, formed in 1766, and the other at Pitgaveny, formed in 1793.

2762. NAIRESHIRE. A surface 17 miles long, by 10 miles broad; the greater part level and fertile.

6763. CROMARTYSHIRE. A peninsular surface of 63,450 acres; chiefly an elevated tract of heath, but with a small extent of arable ground and natural pasturage.

6764. CAITHNESS. A surface of 393,000 acres; generally flat; described by Pennant as an immense moor, with some fertile spots. From the materials which compose this morass, it appears to have been formerly full of trees, but the inhabitants have raised in a few years hundreds at Thrush of seven acres; a remarkable circumstance, as there are none in the counties of Cromarty, Ross, or Sutherland.

Thurso Castle,—near Thurso; Sir J. Sinclair. Chiefly remarkable for agricultural improvements, but displaying also some plantations, and a kitchen-garden, and many ingenious but abortive attempts at amelioration.

6765. THE ORKEY and SHETLAND ISLES contain nothing that we have heard of worthy of notice in the way of gardening. Such a thing as an orchard is unknown in these islands. In Orkey, Neill observes (Gent. Repert. ii. p. 180.), a few apples are produced on wall-trees; in Shetland still fewer, and that only in particularly good seasons.

6766. SÜDERTHERLANDSHIRE. A mountainous uncultivated surface of 1,478,400 acres; about half of which is the property of the Marquis of Stafford, who has enlarged the farms, built new farrieries,

Dunlop Castle, — at Dun Robert; Marquis of Stafford. There is no mansion employed as a residence, but it is a noble mansion in a suburb of Dunfermline, and is devoted to the breeding and feeding of 1000 mountain deer. In the garden, apples, pears, and cherries thrive perfectly well, and every thing might be obtained by the use of glass.

Stobo — at Stobo; — Dumfries, Esq. Extensive plantations have been formed, and in the gardens apricots and walnuts have sometimes ripened.

ROSS-SHIRE. A surface of 1,770,000 acres; the eastern part fertile, and containing some counties with high mountains, but fit only for plantation and pasture. In no part of Scotland have the proprietors been more assiduous in forming public roads, and in planting extensive necessary tracts.

Market-Garden and Orchard. — There are none of the former kind near Inverness, but there are extensive plantations, fit only for plantation and pasture; and which never ripens as an espaleur. At Castle Inver, Novar, and Lenmore, there are extensive plantations, but a tree was to be seen.

Invergordon Castle, — near Invergordon; M. & E. M'Coo. A handsome house, by Gillespie, of Edinburgh, surrounded by flourishing plantations, on grounds eighty feet below the castle.

Fort Augustus, — near Inverness; Sir H. Mooro. A great and finished place, and one of the most complete in the north; the situation of the house is elevated, and it commands a fine view of the bay of Croyman.

Verburgh House, — near Avoch; — A modern dwelling of the most elegant kind. It is situated on a beautiful bank near the sea, and surrounded by a Scottish park, that is, an assemblage of grass-fields, surrounded by trees, and varied by mazes and groves.

Ballangen, — near Kilmuir; Sir J. C. Ross. A most delightful seat, surrounded by an immense extent of planting.

New Tarbat, — near Kilmuir; Earl of Cromarty. A superb modern house, inferior to few seats in Scotland, surrounded by extensive grounds and plantations, which join those of Alloonepark.

Braemar Castle, — near Cray; Lord Seaforth. A fine building, pleasantly situated on the river Conon, and surrounded by extensive and well planted grounds, containing a good kitchen-garden and an extensive collection of exotic and hardy plants.

Red Castle, — near Loch Balmoral; Colonel Grant. An ancient seat, and residence considerably improved.

476. INVERNESS-SHIRE. A surface of 2,000,000 acres, being the largest county in Scotland. It consists of two ranges of mountains, separated by a chain of lakes now united by the Caledonian canal. The valleys are fertile; many of the mountains are covered with natural forests inhabited by the red and roe deer, the elkine and common hare, and other exquisite sorts of game.

Inverness Nursery, — at Inverness; Messrs. Gibbs. A very extensive nursery, and has the most beautiful and choice trees, with branch nurseries at other towns. Here is a very complete nursery orchard of all the hardy fruit-trees which ripen early in the season, and are in full bloom in April; and which are kept fit for propagation are taken.

Gairden Castle, — near Inverness; — Public, and a few private orchards, but some private ones, of which a great part of the produce is sent to London. One of the largest is at Auchinraith, near Inverness. It was planted in 1788, chiefly with the Herefordshire cider apple. The trees are now in a full bearing state. These are the only trees in Scotland which were planted in 1788, and which are not entirely in the same condition as these, and the spaces were regularly cropped, according to the rotation of the farm crops. The trees are now in such a condition that in three branches near the stump, and grass is said to be the preferable under-crop. The old garden at Castle Stewart, belonging to the Duke of Argyll, is another nursery of some extent, and contains an immense variety of deciduous and evergreen trees, may also perhaps be ranked as an orchard. The trees are planted in rows of three or four sides, and are found to be the most profitable.

They are generally of great size, and many of them change their leaves, in such a manner, that they are not only handsome, but often produce most plentiful crops. At Milltown, of Kettall, there are some remarkably large lamas and cajan pear-trees, and a few of the most beautiful trees of any kind. On an apple tree here in the orchard of Easter Lovat, on the river Beauly, covers a space of forty-seven feet in diameter. A fine pear-tree is spoken of, which used to produce sixteen sacks of fruit in a season.

Castle Brolin, — at Inverness; Lord Sutherland. The garden and demesne greatly improved under the direction of Gibbs, now a nurseryman at Inverness. The Canadian rice (Stizus aquation) is naturally in the garden, and is the most promising and extensive planting abounds over the whole estate.

Kirknew, — near Croy; — The gardens laid out with taste; fruitful orchards and extensive woody, embracing an elegant modern house, situated on a rock hanging over and cut out of the face of the rock by a flint old man.

Contrary, — near Croy; — Davison, Esq. A commodious house, and the residence of Mr. and Mrs. Davison. The gardens consists of three sides of a quadrangle, improved by Mr. Adam, beautifully situated on the north side of the Spey. It contains an extensive and noble landscape, in which the park and pleasure grounds, in which it stands of 4000 acres, and the natural forest of Abernethy of 40,000 acres, at the base of the lofty mountains of Cairn-moun.

Eastward lies the wide-bending cultivated vale of Crounade watered by the Spey.

756. ARGYLESHER. An extensive surface of 3800 square miles, consisting of hills and mountains, and having several islands considered as belonging to it. It abounds in lakes and inlets of the sea, and contains many natural woods; but the climate is moist, and excelling in the department of arboriculture, does not excel in gardening. There are some small market-gardens near Inveraray, and excelling in the department of arboriculture, does not excel in gardening. There are some small

576.

BUTHESHER comprehends the islands of Bute and Arran, and some smaller isles; highly, but fitly, adapted to the temperate climate, and in general favorable to the growth of trees and hedges. There are two or three small orchards and market-gardens near Rothesay and Mount Stewart.

Mount Stewart, — near Rothesay; — Lord Mount Stewart. An elegant house, containing a fine view of the island of Gigha, surrounded by extensive plantations, formed by the late marquis, abounding with various sorts of game, and in which the nutmeg is naturally tallied. The gardens contained a good collection of plants; but, excepting the kitchen-garden, they are now in a state of comparative neglect.

Sect. IV. Ireland.

7651. The surface of Ireland, which is estimated at 11,067,712 Irish acres, is much less varied than Scotland and Wales, but rather more so than England, though great part of it consists of bog and wastes, yet these are everywhere improvable by draining and culture, or planting. The climate is more temperate than that of Britain, but also more moist; it is, on the whole, highly favorable to the culture of leaves and roots;
and favorable for all the other branches of gardening. The political situation of the country, and the general absence of proprietors, have prevented much from being done; but, from the cheapness of land and labor, and the natural advantages every where presented, the most extensive parks, pleasure-grounds, and kitchen-gardens, might be created at a comparatively moderate expense.

7652. The names of residences here given are selected from the Traveller's Guide, published in Dublin in 1819: the characteristic epitaths added are from that work, and the English reader will of course make due allowance for Irish phraseology. We have made the general tour of Ireland, and been engaged professionally in three or four countries, and we know that many places, styled delightful and enchanting in the "Guide," would cut but a poor figure if placed beside hundreds of seats in England whose names we have omitted. There is very little old timber in Ireland, and very few of the "demesnes" that have any other park than a grass field, without trees, in which the house stands. Deer parks are rare, and also kitchen-gardens with hot-houses. Mackay of the Trinity College botanic garden, and McLeish of Harold's Cross, are well calculated for furnishing designs for both these improvements, and happily there is at present a spirit for employing these gentlemen. If to this the proprietors would join a more constant residence on their estates, much would be effected.

PROVINCE OF LEINSTER.

7653. DUBLIN. A fertile surface of 147,540 Irish acres, little varied, but well adapted for horticulture and floriculture. At Dublin is a royal park; two excellent botanic gardens; two good nurseries by Simp- son, Toole, and Mackay, and Grimwoods and Keefo, with some culinary commercial gardens. In Dublin is St. Stephen's Green, a very large naked square, a design for ornamenting which by A. McLeish is about to be published.

The Phoenix Park,—near Dublin; a public promenade and a sporting ground, and a royal park, set apart for pleasure and recreation, and exchanged with woodland, champaign and rising grounds, tastefully adapted for walks, walks of beauty, and walks with deer. The civic regal residence here is respectable and commodious. The kitchen-garden of the Chief Secretary's lodge is reckoned one of the best managed in the county of Dublin.

The Botanic Garden,—at Glasnevin (fig. 757.) Dublin So-
ciety. Established with the commencement of the 19th cen-
tury, chiefly through the exertions of Dr. Wade, author of several works on Irish botany. It is situated at Glasnevin, within two miles of Dublin Castle, and contains 50 statute acres. "Nothing," the authors of the History of Dublin ob-
serve, "can exceed the command of space which the irre-
regular beauty of the surface presents, and of which the planners (chiefly Dr. Wade) of the garden have been careful to avail themselves, having arranged every botanic purpose, they have not sacrificed taste to convenience, or disturbed such objects as contributed to the beauty of the old demesne, origin-
ally that of Tikkel the poet. The summit, having considerable elevation, gradually or abruptly slopes to the river Tolka, which forms a sweeping boundary to one side of the garden. Here large clumps of venerable elms, or other forest trees, shade the sloping steps, or, running along the slopes, separate the ground into irregular divisions. Through these the ivy-
crowned ruin of some venerable arch presents a passage, so that many of the compartments are approached by some picturesque or striking entrance. Nor is the systematic ar-
rangement less judiciously managed. Nothing can be con-
ceived more ungraceful than the formal regularity necessary in such an arrangement; every plant following in its order, and labelled with its name, presents to the eye an irksome sameness.

To avoid this appearance, each class is subdivided into smaller compartments, and situated in various groups, determined by the wind, and by the inequalities of the ground. These improvements are in various stages of execution, and the series of plants follow each other in such succession that the most impatient may be immediately satisfied, the whole forming a part of the best contrived collection of plants.

This garden contains the following arrangements, or sub-
divisions:

A Hortus Linnealis (e), subdivided into a herbarious division, and one for shrubs, fruit-bearing, and forest trees. Six acres are assigned to this division. To each plant is prefixed a metal label, inscribed with its name in the Linnean catalogue.

A Hortus Jussieusianus (b), rather limited, yet sufficiently extensive to comprise all the orders of which there are hardy specimens introduced in Britain.

A Hortus Hiericus (c), or garden of native Irish plants, containing upwards of 1,354 species, including Cryptogamia.

A Hortus occidentalis (d), containing not only the usual cul-
inary vegetables, but all those which in whole or in part are
mitritious qualities reside, in such a degree that they can be con-
verted into human aliment.

A Hortus medicus (o), or garden of plants used in medicine, arranged on the plan of Woudt's (q), and containing every plant in which any medical virtue is known to reside.

A Botanicus ruralis (f), or cottage garden, in which are arranged all plants which the animal to whom the plant is appropriate is fond of eating, and which are wholesome food for it; also such as he is not fond of eating, though not un-
wholesome. (On the opposite side are arranged such plants as the same animal will eat, but which are not wholesome food, and likewise as if it refuses to eat whether nutritious or not. Each order is subdivided in the label, and the whole is managed in a similar manner to the last, and likewise whether the plant be indigenous or foreign.

A Hortus rusticus (q), or garden of plants used in rural eco-
nomics, consisting of grasses, clover, &c.

A Hortus floridus (s), containing all the plants used in dyers' gardens, and which are indigenous to Ireland.

A Hortus plantarum volubildum, repentina et saessentia, (k) or garden of twining, creeping, and climbing plants, shrubby and herbaceous.

A Hortus plantarum saxatilm, or garden of rock plants on rock-work. This is formed on an artificial mound, construct-
ed on the most elevated part of the garden. "The fragments of rock for this purpose were transported from the Hill of Howth, and such was selected as were already clothed with various species of mosses and lichens. These were piled together without any apparent order, so as to give the appearance of a natural rocky mound. But it so constructed that spider's walking routes, sides, but not visible at a dis-
tance, conducts the visitor to the summit. Here, as he as-
cends the steps, winding round the sides, but not visible at a dis-
tance, conducts the visitor to the summit. Here, as he as-
cends the steps, winding round the sides, but not visible at a dis-
tance, conducts the visitor to the summit. Here, as he as-
cends the steps, winding round the sides, but not visible at a dis-
tance, conducts the visitor to the summit. Here, as he as-
cends the steps, winding round the sides, but not visible at a dis-
tance, conducts the visitor to the summit. Here, as he as-
cends the steps, winding round the sides, but not visible at a dis-
tance, conducts the visitor to the summit. Here, as he as-
cends the steps, winding round the sides, but not visible at a dis-
tance, conducts the visitor to the summit. Here, as he as-
cends the steps, winding round the sides, but not visible at a dis-
tance, conducts the visitor to the summit. Here, as he as-
cends the steps, winding round the sides, but not visible at a dis-
tance, conducts the visitor to the summit. Here, as he as-
cends the steps, winding round the sides, but not visible at a dis-
tance, conducts the visitor to the summit. Here, as he as-
cends the steps, winding round the sides, but not visible at a dis-
tance, conducts the visitor to the summit. Here, as he as-
cends the steps, winding round the sides, but not visible at a dis-
tance, conducts the visitor to the summit. Here, as he as-
cends the steps, winding round the sides, but not visible at a dis-
tance, conducts the visitor to the summit. Here, as he as-
cends the steps, winding round the sides, but not visible at a dis-
tance, conducts the visitor to the summit. Here, as he as-
cends the steps, winding round the sides, but not visible at a dis-
tance, conducts the visitor to the summit. Here, as he as-
cends the steps, winding round the sides, but not visible at a dis-
tance, conducts the visitor to the summit. Here, as he as-
cends the steps, winding round the sides, but not visible at a dis-
tance, conducts the visitor to the summit. Here, as he as-
cends the steps, winding round the sides, but not visible at a dis-
tance, conducts the visitor to the summit. Here, as he as-

cends the steps, winding round the sides, but not visible at a dis-

(File text continues)
Gardens of Ireland.

Of Villa Gardens.—There are a very considerable number that might be enumerated, such as St. Catherine's, belonging to the bankers Lasker; St. Woodman;—Lane Esq., Mount Sackville;—M'Kermit, Esq, Edenderry;—Norham, Esq, Donnybrook, Dr. Percival; those of Miss Colville, Miss Smyth, Mrs. M'Veyan, besides a number near Bray, Lucan, Kilbirn, Clonsilla, &c.

Clare Hall, — near Donnybrook; — Stupendous rocks scenery, with old trees in the park.

Sherrin, — near Dublin; Earl of Charlemont. A delightful edifice, in the form of a Turkish palace, built, with a fine ornamental temple. The grounds are thrown open to the Dublin citizens two days a week.

Loughe's Park, — near Donnybrook, — the lake at the bottom of the Dublin mountains, and abounding in picturesque views from the house and walks in the pleasure-ground.

The Marquis of Drogheda's, near Enniscoe, Esq. A house and gardens; and a varied collection of plants, judiciously arranged by an excellent botanist and gardener, and a man of general information.

Mount Merriman, — near Donnybrook; — Lord Fitzwilliam. A magnificent mansion and grounds. A house of great beauty, and containing one of the best green-houses in the country.

Northdown Park, — near Donnybrook; — a magnificent mansion on an elevated ground.

Kyllitter, — Lord Newcomen. A fine situation; the kitchen-garden remarkable for its grapes and vines.

Kingstown, — The Right Hon. W. Saurin, A small garden, but rich in exotic productions, fruits, and flowers, and especially of bulbous exotics.

Rathfarnham Castle, — near Rathfarnham; — A magnificent mansion, embellished by many extensive grounds.

Tohall Palace, — at Tullow; — Archbishop of Dublin. An ancient venerable structure, with extensive gardens, kept in fine order.

Lord Rossmore. Extensive plantations, and a waterfall of 100 feet, in what is called the Devil's Glen.

Powerstown, — near Enniskerry; Lord Powercourt. An extensive-forest park, in a romantic situation, entered by a fine avenue, planted, and ornamented with water and buildings.

Bracken Castle, — near Miltown; — Lord Powerscourt. A house situated on the river Dargle, with a luxuriance of rural beauties.

Blessington Park, — near Blessington; Marquis of Downshire. A fine park; the house consumed in the rebellion of 1798, and not yet rebuilt. This place was formerly famous for the first kitchen-garden in Ireland, situated at Rushborough, — near Naas; Earl Milltown. The front of the house and grounds are finer and more extensive, with superb stonework, nearly 700 feet long. The grounds finely varied and well planted.

Lord Desart. A magnificent mansion, and extensive grounds.

Ballyroan, — near Durrow; — Lord Ashbrooke. A magnificent mansion, with an extensive demesne.

Loddon Abbey, — near Enniskerry; — Bishop Keating. A magnificent mansion, and extensive grounds.

Arthursbrook, — near Durrow; — Lord Ashbrooke. A magnificent mansion, and extensive grounds.

Lodges on both sides of the river.

5.6.

Wicklow. A finely varied street of 305,404 Irish acres; with fine dells and brooks, and bordering on the sea.

Belfield, — near Bray; — Dr. Latschus, Esq. A romantic residence, with extensive gardens and hot-houses, on which no expense is spared to preserve their reputation of being the first of their kind in Ireland.

Glenmore Castle, — F. Synge, Esq. Extensive mountain plantations, grotesque rock masses, and views, and prospect reaching even to Wales; hot-houses and flower-grounds.

Clonmanning, — Rev. Dr. Trelaw. Extensive kitchen-gardens, and the first cast-iron hot-houses erected in Ireland, and the plantations correspond in magnitude.

765. KILDARE. A flat surface of 212,425 Irish acres.

Bishop-court, — near Kill; — Lord Powers. A magnificent mansion and highly cultivated demesne.

Ducketts Grove, — near Kill; — Lord Aldborough. A beautiful seat with extensive plantations.

Castletown, — near Celbridge; — A mansion of the Earls of Charleville. A superb, an edifice of beauty in every respect. A superb mansion.

Castle Leslie, — near Tullamore; — Earl of Charleville. A picturesque seat, containing extensive views of the natural forest, on which the present earl has built a magnificent and commodious mansion in the casadell style, and laid out the grounds with skill and elegance.

765. KILDARE. A surface of 282,200 bog or waste.

Charleville Forest, — near Tullamore; — Earl of Charleville. A magnificent seat, containing extensive views of the natural forest, on which the present earl has built a magnificent and commodious mansion in the casadell style, and laid out the grounds with skill and elegance.

765. QUEEN'S COUNTY. A surface of 230,300 acres of bog or waste.

Stradbally Hall, — near Stradbally; — Colonel, Esq. A beautiful residence.

Brookley Park, — near Stradbally; — Earl Roden.

766. CARLOW. A surface of 157,000 acres of grand and picturesque surface and good soil.

766. EASTMEATH. A surface of 225,500 acres, generally flat, but with only a moderate portion of bog and waste.

Gorminstown House, — near White Cross; Lord Gorminstown.

Stowe Castle, — near Slane; Earl Cunyngham. A splendid mansion, near erecting, and the grounds, through which flows a river, containing and being otherwise improved.

766. WESTMEATH. A surface of 249,565 acres of bog, hills, a number of lakes, and some fertile ground.

Gartnafurey Park, — near Gaulstown; — Lord Killmaine. A superb residence.

Headfort, — Earl of Bective. A princely residence, with extensive views, commanding hills, rocks, ruined towers, and rich farms. From a prospect tower on the hill of Lloyd, upward of twelve counties are seen. There is much old

Donny Castle, — near Dunsahquin; — Lord Dunseay. Ar dhurri Math. A chase and a splendid park.

Heastfort, — near Kells; Marquis Bective. A magnificent mansion, and extensive and beautifully planted demesne.
timber, and the finest larches in Ireland. The house, gar-
den, and grounds have been much neglected, and are renew-
ing and improving under the guidance of Mr. Leish.

Castle O'Donohue. — A most ancient house, 1700 acres. — A
fine mansion and beautiful demesne.

Trahernahy, — near Marinstown; Sir P. Piers.

Lisken, — near Mullingar; H. O'Beall, Esq. — A
charming residence.

Ballygreen, — near Mullingar; H. O'Beally, Esq. — A
charming residence.

Ballykennar, — near Castle Pollard; Earl Longford. A
spacious seat.

Lismalin Castle, — Captain Purdon of Lisnalin. A house, offices, and
gardens, by Sir J. G. Smyth; 160 acres; extensive pros-
spects, some old trees, and numerous young ones.

Kwick Dris, — Sir K. Levinge, Bart. A large castle, by Sir
K. Levinge, Bart., of 100 acres of oak and poplar.

Longford. — A surface of 154,700 acres, of rich and beautiful spots, interspersed with bogs, mountains, morasses, and fens.

Caste Forbes, — near Newtown Forbes; Earl Granard. A splendid residence.

Barnsnaheen, — near Clogeenhead; Sir E. fellow. A char-
ing residence, encircled with an extensive and well planted
demesne.

Roscommon. — near Tranmer; — A well planted
demesne.

Corraghmore, — near Waterford; Marquis of Waterford. An ex-
tensive seat, which for beauty and variety cannot be
surpassed in any part of the united kingdom.

Cork. — The largest county in Ireland, comprising a surface of 1,048,700 Irish acres, of which 231,959 are bog, mountains, and waste. There is a nursery by Thomas Sheehan.

Cork Botanic Garden. — was founded in 1802; by the Royal
Cork Institution (a society of gentlemen incorporated after
the manner of the Dublin Society, and like that society sup-
ported by subscriptions) — six acres are en-
closed by a hedge, and one acre near the centre by a wall;
includes a hot-house and greenhouse. The plants in the
garden are arranged in the Linnean manner; it is managed
by a committee, and the curator is Mr. James Drummond, A. L. L., and intelligent gardener.

Tipperary. — A surface of 554,950 Irish acres, but level and fertile in the cast, where the lands are

Kilmecra, — near Cloonn; — Bagnal, Esq. — A beautiful
seat.

Kilcolgan, — near Cloonmel; Sir T. Osborne. A near
mansion.

Knockalatty, — near Cloonn; Lord Donoughmore. An en-
chanting residence on the banks of the Suir, finely planted.

Shancally, — near Clooneg; Lord Lisnane. A splendid resi-
dence.

Killargally, — near Balloypen; Sir W. Barker. A delightful
residence.

Cahed Palace, — near Cashel; Bishop of Cashel. The gar-
dens beautiful and tastefully arranged.

Limerick. — A surface of 395,730 Irish acres, generally flat and very rich, especially the tract of low lands on the Shannon, which are deemed the richest and most prolific in Ireland. There is a nursery at the county town, by Thomas Less.

Ballinur, — near Asketon; — Massey, Esq. — A beautiful seat.

Clare. — A surface of 476,200 Irish acres, of which more than half is bog, mountainous, and waste; the mountains numerous, and the soil and surface of the lower grounds very various.

Inishalony, — in the village; the castle of the elder branch of the O'Brien family.

Kerry. — A surface of 647,650 Irish acres, much varied in surface and soil, and to a tourist the most interesting country in Ireland, as containing the lakes of Killarney.

Mount Murchell, — near Castle Island; O'Donoghue, Esq. A char-
ing residence.

Keneigue Lodge, — near Kenmare; Marquis of Lansdown.

Kenne cure House, — near Killarney; Lord Kenmare. A delightful resi-
dence, where the banks of the river Donagh, at the
mouth of which the aquatic excursions of the lakes is

commenced. Round the lakes of Killarney is Belleview, and various houses of little or no interest, other wise than from their situation. The banks and islands of the lakes are rich enough to admit of the most magnificent and the most surprising species of arbuthnotume, as well as grand and picturesque views.

Provinces of Connaught.

Roscommon. — A surface of 346,970 Irish acres, with some lofty hills, but no lakes of any mag-
nitude: it is generally in pasture.

Clarke, — near Mount Talbot; — Lateshe, Esq. — A
beautiful residence.

Fenwegian, — near Belanagh; — A delightful residence.

Galway. — A surface of 998,970 Irish acres; varied and rich, but without hills or mountains:

generally in pasture.

Portumna Castle, — near Portumna; Marquis of Clarick-
ard. A venerable mansion.

Shannon Hill, — near Portumna; Lord Riverton. A delight-
ful residence.

Portumna Garden, — near Eyrecourt; Pearce, Esq. — A
beautiful residence.

Dolgyn, — near Woodford; Right Hon. D. B. Daly. A
fine mansion and well planted demesne.

Quernstown, — near Eyrecourt; Earl Louth. A fine
seat.

Lough Mask, — Lord Smyth; Esq. — A fine seat.

Gortnakevy, — near Ballinaclava; Lord Clancarty. A splendid
residence.
7653. MAYO. A surface of 790,600 Irish acres; a great portion mountainous and waste, and the rest chiefly in pasture.

Castlebar, near Castlebar; LordLucan. A venerable structure, solidly situated on the brow of a steep eminence.

Moate, near Ballinrobe; Sir B. R. Lynch. A delightful residence.

Neale, near Ballinrobe; Lord Kilmaine. A magnificent mansion and extensive demesne.

7654. LEITRIM. A surface of 355,850 Irish acres; hilly, with fertile slopes and valleys, and a great part well adapted for every branch of gardening.

Lurgan, near Lurgan Bay; Right Hon. S. Waine. A beautiful residence.

7655. SLIGO. A surface of 247,150 acres, nearly the third quite waste, the rest fertile in corn and potatoes.

Hazletown, near Sligo, on Lough Gill; — — — —. The house and demesne aptly composed in elegant magnificence.

PROVINCE OF ULSTER.

7676. CAVAN. A surface of 301,000 Irish acres, abounding in fenny pastures and coarse grounds.

Floriana, near Swadliden; Earl Enniskillen. A splendid residence.

Farnham House, near Kilmore; Lord Farnham. A splendid residence, in an extensive demesne, abounding in lakes, hedgerows, and meadows; an extensive demeans-farm, under the care of a Northumbrian agriculturist. All the upper servants English.

7677. FERMANAGH. A surface of 283,400 Irish acres, chiefly boggy and mountainous; interesting to tourists as containing Loch Erne.

Belfast, on an island in Loch Erne; Earl Ross. The island contains 800 acres, charmingly diversified by hills, dales, and gentle declivities, which are richly clothed with old timber, through which gravel-walks are conducted, and a temple erected, from which a panoramic view is obtained, not only of this, but of all the other wooded islands of the loch. One of them is exclusively used as a deer park.

Lough Neagh, — — — —. A lake, thickly interspersed with islands richly planted with trees, a great portion rough and mountainous.

7678. MONAGHAN. A surface of 179,800 Irish acres, much encumbered with bogs and mountains, but in part rich and cultivated.

Castle Blane, near the village of that name; Lord Blane. A delightful residence, commanding a fine view of the county.

7679. TYRONE. A surface of 467,700 Irish acres.

Borough Court, near Newton Stewart; Marquis of Abercorn. A magnificent mansion, but no park or garden or gardens deserving notice. Extensive plantations, however, have been made, and various parts of the demesne.

Caledon Hill, — — — —. A delightful residence.

7680. DONEGAL. A surface of 679,550 Irish acres; the greatest portion reclaimable and irreclaimable mountains.

Lurgan, near Lurgan; Right Hon. W. Brownlow. A delightful residence. Near this seat is Lough Neagh, a lake of 80,341 acres.

7681. DERRY. A surface of 315,300 acres; its surface varied but without mountains, and the soil generally fertile.

7682. ARMAGH. A surface of 181,450 acres, with an irregular surface that has not unaptly been compared to eggs placed on end in a basket of salt.

Castle Gosford, — — — —. Lord Gosford. An extensive demesne fringed with trees.

Castle Dillon, near Richill; Sir C. Molyns. An extensive demesne, containing a handsome sheet of water, skirted by the branches of a hill covered with a very thriving plantation.

7683. DOWN. A surface of 349,500 Irish acres, moors.

Neale Castle, near Moira; Marquis of Hastings. Contains some old trees; also some young plantations; gardens in all its branches having been here attended to by the present owner, father, when neglected in almost every other part of Ireland.

Hillsborough Castle, near Hillsborough; Marquis of Downshire. A magnificent residence.

Belvoir, near Newtown Breda; Lord Dungannon. A magnificent residence.

7684. ANTRIM. A surface of 420,999 Irish acres, considerably varied with mountains and hills, fertile valleys, bogs, and dry wastes. It is noted by tourists as containing the Giant’s Causeway. There are two nurseries at Belfast.

Shane’s Castle, near Antrim, on the borders of Lough Neagh; Lord O’Neill. An enchanting residence.

Glennarm Castle, near Glenarm; Earl Antrim. A venerable and magnificent mansion.

Chap. IV.

Of the Literature of Gardening.

7685. The first books on agriculture and gardening were written by the Greeks some centuries before the Christian era; and by the Romans about the commencement of that period. Among the ancient Greek writers, Hesiod, Homer, Theophrastus, Xenophon, and Ælian, may be mentioned as having touched more or less on gardening. The works of the modern Greeks, or those who wrote after the seat of the Roman government was transferred to Constantinople, are collected under the title of Geoponica; and have been translated by T. Owen, who also translated Varro and Palladius. Among the Latins, the works of Varro are the first in the order of time; next Cato, and Pliny, and Columella, and, lastly, R. T. E. Palladius, supposed to have lived in the fourth century. Passages relative to the subject may be found in most of the Roman poets, especially in Martial, Virgil, and Horace; but Pliny’s natural history, and Columella’s 11th book on gardens, are those from which the most correct ideas may be obtained of Roman gardens. In the ages which succeeded the fall of the Roman empire, few books were written, excepting on religion: the first which appeared on rural matters was by
Crescenzo, in Italy, early in the fifteenth century; and soon after one or two in France, Germany, and Britain. We shall enumerate the whole of the British works on gardening, as far as we have been able to collect their titles; and next, the leading works of France, Germany, Italy, Spain, Sweden, Russia, and America.

**SECT. I. Of the Literature of British Gardening.**

7686. *The first British work on husbandry* is that of Judge Fitzherbert, published about the middle of the 16th century. Before the end of the same century appeared Tusser, Mountain, Mascall, and Hyll, who wrote expressly on gardening, partly from their own experience and observation, and partly by translating from the Latin and Greek authors. In the seventeenth century appeared as gardening authors, Plat, Lawson, Gardiner, Standish, Parkinson, Plattes, Austin, Tradescant, Evelyn, Cowley, Blake, Rea, Worlidge, Meager, Temple, and some others. Those of the succeeding century are numerous, and consist in great part of practical or professional gardeners, who wrote from their own experience; of these are London and Wise, Collins, Switzer, Fairchild, Miller, Cowell, Hitt, Hill, Wheeler, Boucher, Swinden, Abercrombie, Speckley, Forsyth, Maddock, M'Phail, Repton, and Nicol.

7687. Of *amateur gardeners and botanists*, who wrote on gardening during the eighteenth century, there are Laurence, Bradley, Evelyn, Justice, Hanbury, Weston, Wheatley, Chambers, G. Mason, Mason the poet, Anderson, R. P. Knight, T. A. Knight, U. Price, M. Marshall, and C. Marshall. The nineteenth century has produced one or two practical authors, as Pontey, Hayward, Emmerton, and Hogg; one gentleman writer on the subject, Hope; besides a number of authors of both classes, who have contributed papers to the Horticultural Societies.

7688. *The old gardening books previous to the Restoration*, Professor Martyn observes (Pref. to Mill. Dict. xxxv.), "are of very inferior value, with scarcely any pretence to originality, if we except Scot, Lawson, Parkinson, and Austen. Evelyn made a new era in planting and gardening. His first work was from the French, and published before the Restoration; but his great work, *The Silent*, was original, delivered before the Royal Society in 1662, and first printed in 1664. The same year his *Gardener's Almanac* was also published, and maintained its ground until Miller's *Calendar* appeared. Cook assisted him in the article of planting; Sharrock and Rea in that of gardening, which Cowley and Rapin ornamented with the flowers of poetry. Quantiniey, with his followers, London and Wise, figured in gardening at the end of the same century: Liger, Laurence, and Bradley, at the beginning of the next; these were followed by Switzer and Fairchild, who lead us to the time of Miller, in 1724. Contemporaries with Miller were Baty Langley and Cowell. Miller, during his long career, had no considerable competitor, until he approached the end of it, when several writers took the advantage of his unwearied labors of near half a century, and fixed themselves upon him, as various marine insects do upon a decaying shellfish. I except Hitt and Justice, who are both originals; as is also Hill, after his fashion; but his gardening is not much founded in experience."

7690. *The most useful works on gardening at the present time* are, in horticulture, those of Forsyth, Nicol, and Abercrombie; in floriculture, that of Maddock; in arboriculture, those of Pontey and Sang; and in landscape-gardening, those of Wheatley and Repton. In the transactions of the horticultural societies are some valuable and original communications on the first branches, and especially on horticulture. In enumerating the principal British works on gardening, including some few of those on husbandry and botany, naturally connected with our subject, we shall adopt the order of the appearance of their authors, as writers on gardening; and when we can, we shall give short biographical notices. Those authors who have merely written articles published in the transactions of societies, or in public journals or magazines, are not here included, unless they have also written separate works.
BRITISH WORKS ON GARDENING. 1699

SUBJECT. I. British Works on Gardening.

The Customs of London, from the time of Richard I., &c. Commonly entitled Arnold's Chronicke, and first printed at Antwerp in 1502, fol.; reprinted along with a series of English tracts, Lond. 4to. 1696, with a new and augmented edition, divided into chapters, and contains the following articles:

The act for trees above 20 years growing to pay no taxes. The order for the sale of good and planting, of seeds, as well as in colours. A treatise of the four elements. The order for the sale of good and planting, of the foame and meet to make land by. Verycely (probably coryly) to grow in an hour space, &c. 1522.

The Grecse herbals, which gyfte puryfie knowledge and understanding of the life and commodities of all plants, veris.

Peter Tauer was the first printer in Southwark; the book to which he alledged he was "the Grecse Herbals, 1546," and the first or second production which issued from his press. About 1541, he became one of the citizens of London, and resided in Essex, 1516, received a liberal education at Eton school, and at Trinity-hall, Cambridge; lived many years as a farmer in Suffolk, and afterwards removed to London, where he published his first work in 1557, and died in 1580.

1. Five Hundred Points of Good Husbandry, as well for the Vineyard, as Orchard and Open Country. Lond. 1557-4to.

2. A short Divisition, entitled, Five Hundred Points of Good Husbandry, visited to many of Good Husband's; first devided and now lately augmented, with divers approved London Practise for Gardening. Lond. 1575-4to.

1571. Mountain, Didymus.

1. The Gardener's Labyrinth; containing a Discourse of the Gardener's Life, in the yearly travauls to be bestowed on him, in the care and attendance of his garden, with the choice of Seedes, & apt times for Sowing, Settling, and Planting of Such Trees, as are most fruitful in England, and hath serving to that use and purpose; wherein are set forth, divers Herbes, Knower of Maizes, cunningly handled for the beautifying of Gardens; also the Physicke of eche Herbe, &c. Gathered out of the best approved Writers of Gardening, Herbes, Herb-Greenke, &c. and the best author. 1571.

2. The Second Part of the Gardener's Labyrinth; vittering such Curiosities and Amusements, as are not in the former Part, particular sowing and removing of the moste Kitchen Herbes; with the wittie ordering of other dainty Herbes, detectible Flowers, and such Herbes and Plants, both as artificers and botanists cannot heretofore bin vittered of; besides the Physikke benefits, and the Lemons of the Immodest Herbes, and such as are disliked out of them, right necessitate to be knowned. Lond. 1574-4to.

1574. Hill, Hyll, or Hyle, Thomas, a London author of various works on Dreams, Physick, Mysteries, an Almanac, Astronomy, Arithmetic, &c.; died in the beginning of the seventeenth century.

The Profitable Arte of Gardening; to which is added many interesting and curious particulars relative to the Physikke helps belonging to eache herbe, and that easily prepar'd and serv'd. There are also beene twente or more plants, and the best entitlest the Marvallous Government, Propertie, and Benefique of Bees, with the rare Secretes of the Bonnie and Waxe. And in the end, is set downe, howe to raise Bees and Plants, but not heretofore bin vittered of; besides the Physikke benefits, and the Lemons of the Immodest Herbes, and such as are disliked out of them, right necessitate to be knowned. Lond. 1574-4to.

1594. Platt, Sir Hugh, author of various philoso.

He also wrote and appeared only the dedication of the Groundes of gardening. He must have had a numerous family, for six of his children died of the worms. It appears from his Garden of Eden (p. 80.), that he lived in Bishop's-hall, near Holborn, in 1601; and that he had a garden in St. Martin's lane.

1. The Jewell House of Art and Nature, containing divers rares and not hitherto beheld plants, after strange experiments in the Art of Husbandry, Dissimulation, and moulding of the Earth; driven downe, according to the Author's own experience, by Hugh Platte, of Lincolne Inne, gentleman. Lond. 1594-4to.

2. The Garden of Eden for an accurate Description of all Flowers and Fruites now growing in England, with particular Rules how to advance their Nature and Growth, as well in Seeds and Herbes, as the secret ordering of Trees and Plants. But he learned that he observed, Sir Hugh Platt, knight. The fifth edition. Lond. 1660. small 8vo.

1597. Gerarde, John, a surgeon and famous herba.

He lived in Holborn, where he had a large garden, one of the first attempts of the kind in England.

The Herbal, or General History of Plants, gathered by John Gerarde, London, 1597. 4to.

1597. Lawson, William, a practical author, who wrote, besides his Orchard, Tractatus de Agricultura 1596. 4to., and his Ortus Paradisi, or the Perfect Arte of Planting, with all the necessaries, and not to delight in curious conceits as planting and grafting with the roots upwards, inoculating roses on thorns, and other freaks of this sort. 1599. 4to.

A New and Invaluable Treatise of the best way for Planting, Grafting, and to make any Good ground good for a rich Orchard; with the best rules for the raising of Flowers, Plants and Trees, the whole Commonwealth; with the Country House's Garde for Husbandry, or open Country life; their Virtues, Seasons, Pro.

Ornaments; variety of Knots, Models for Trees, and Plants, for the best ordering of Grounds and Walks. As also the Husbandman's use and practice, with several Uses and Amoy.

ances: all being the experience of forty and eight year's labor, and now printed for the first time corrected, and much enlarged. Whereunto is newly added, the Art of Propagating Plants, with the true ordering of all manner of Fruits, in their Gathering, carrying Home, and Preservation. London, 4to. Followed by a most profitable new Treatise, from approved experience, the Art of Propagating Plants. By Simon Harsward.

1614. Anon.

The Flowerer's Secrets, 4to. black letter. It contains some curious directions for preserving fruits and other garden-productions.

1612. C - R. -

An Old Thirld newly revived, by R. C. of Planting and Preserving Flowers and Herbs, &c. By R. C. 1614. 4to in four parts.

1613. Standish, Arthur.

New Directions of Experience, authorised by the King's most excellent Majesty, as may appear, for the Planting of Fruits, as well Of Trees, &c. The North and South Wood may be raised from hedges as may plentifully main.

taine the requisite yearly demand. Also how to raise, traine, and plant such trees, that within thirty years all spring woods may be converted to tillage and pasture. Lond. 1614.

1620. Bacon, Francis, of St. Albans, a most distinguished philosopher, and high-chance.

The most eminent plants in the reign of James I., was born in 1618. To these is likewise added a Treatise of the Arte (First Namented two or three.?) by Thomas Hyll, citizen of London. Lond. 1574-4to.

Instructions how to plant and dress vines, and to make wine, and how to dry raisins, figs, and other fruits, and also olives, oranges, lemons, pomegranates, almonds, and many other fruits. Printed with his Treatise on the Art of making Silk paper, Lond. 1622.

1623. Markham, Gervase, Jarise, or Gervas, an English author who wrote on a great variety of subjects during the reigns of James I. and Charles I., and died about 1656. He appears, says Harte (Essays, ii. 32.), to be the first Englishman who des.

1626. Parkinson, John, a celebrated herbalist and botanist; born in 1567, bred an apothecary, and acted in the capacity of an apothecary and professor of botany to James I. and Charles I.; died about 1640. Professor Martyn says his Paradisus is the first garden book worth mentioning, and that considering what hath beene on this subject, with it, has the greatest merit.

1633. Parkinson. Sir John, in his Paradisus Territorii, or, a Garden of all sort of plants which grow in England, is first neces.

1651. Observations on Sir Francis Bacon's Natural History, so far as it concerns fruit-trees, &c.
1655. Platten, Gabriel, a poor man, but a useful writer. Harte says, he had a bold adventurous curiosity, which somewhat inclined the faculty medickority. As great a genius as he was, he was allowed to drop down dead in London streets with his pen in his hand, before the very watch which he died.

He bequeathed his papers to Hartlib, who seems to have published but few of them.

1. Treatise of Infallible Happiness, 1654. Lond.
2. Discourse of Infallible Treasure, hidden since the World's beginning, in the way of Husbandry. Lond. 1659. 1638. 1656. 4to. 4to. 4to. 4to. 4to.

1. The Countryman's Recreation; or, the art of Planting, Grafting, and Gardening, in three books. Lond. 1640. 4to. While he was a Houblon at Leyden, 1641.
2. The expert Gardener, collected out of Dutch and French authors, with some peculiar instances of plants, and fruits, printed along with the work entitled, A Treatise on Fruit Trees.
3. Observations on some parts of Esen's Natural History, as it is exhibited in the first five volumes, and in the New Edition.
4. General Advertisement concerning Cider. — Letters about Improvement of Nurseries, Orchards, &c. Lond. 1677. 4to. 4to. 4to. 4to.

1645. Westen, Sir Richard, of Sutton, in Surrey. He was ambassador from England to Frederick V. Elector Palatine and King of Bohemia, in 1619. He was a great author, both in Latin and English, and his curious relation of it in a letter is still preserved in MS. It is remarked in the Philosophical Transactions, that England has profited in agriculture to the amount of many millions in consequence of the Flanders husbandry having been made known by Sir R. Weston's book.

A tract, issued in Brabant and Flanders; shewing the wonderful improvement of land there; and some rules for that practice in this Commonwealth. Lond. 1645. 4to. 94 pages.

1645. Hall, Joseph. This author lived at Sheldon, in Worcestershire, and an extract from his work may be seen in the Museum Ruticum.

1650. Brown, Sir Walter, an officer in Cromwell's army, who, with other English gentlemen, holding commissions at that time, was eminently useful in introducing improvements into Ireland in agriculture.

The English Improver Improved; or, the Survey of Husbandry Surveyed, discovering the Improvements of all lands, with a number of Improvements. This is an original and incomparable work for the time. It is remarkable, as an impecunious writer on agriculture, and author of several theological tracts, was the son of a Polish merchant, and came to England about 1640. He was a great promoter of humane learning, and the study of languages, and was much esteemed by all ingenous men in those days. Milton addressed him his treatise on education, and Sir William Petty inscribed two books to this author. John Dryden allowed him a pension of a hundred pounds a-year.

A Design for Flints, by an universal Planting of Fruits, in England, and a method of newing English Towns. The author of this was a writer on agriculture, and author of several theological tracts, was the son of a Polish merchant, and came to England about 1640. He was a great promoter of humane learning, and the study of languages, and was much esteemed by all ingenious men in those days. Milton addressed him his treatise on education, and Sir William Petty inscribed two books to this author. John Dryden allowed him a pension of a hundred pounds a-year.

out in the fields all night. This gave Cowley the fever, which carried him off." He disliked women, and seems to have returned one day, to retire to
it in his poems; but, according to Dr. Johnson, was unhappily when he had attained his wishes.

1675. Hughes, William. The Complete Vinegar; or, an excellent way for
the planting of Vinegar, and ordering of Wines and Wine-presses, according to the German and French manner. Lond. 1670. 8vo.

2. The American Physician, or a Treatise of the Rootes, Plants, Trees, and Herbs growing in the English Plantations; with a Discourse on the Cocoa Tree, and the ways of making Chocolate, &c. Lond. 1670. 12mo.

3. The Flower Garden: how most Flowers are ordered, increased, &c. Lond. 1672. 12mo.

1676. Agreslick, a garden, seems to have been a professional gardener, and to have given plans for laying out grounds.

Forbes, John, gardener to Charles II. at St.
James's.

1675. John, gardener to Sir J. John, of Aylesbury. 1670. 4to.

1. Systema Agriculturae, the Mystery of Husbandry dis-

1672. Drope, Francis, B.D., a native of Cumner in Berkshire, where his father was vicar, and his brother a physician. Francis died at Oxford, and this work was published after his death by his brother, and dedicated to Lord Windham, who is stated to have a fine orchard at Brackley.

1675. Cotton, Charles, Esq., an ingenious poet, born in Staffordshire. 1633. 8vo. Among a number of political
works, memoirs, poems, &c., and editor of Walton's Angler; died 1687.

1676. Cooke, Moses, gardener to the Earl of Essex at Cashibury. Evelyn in his Diary mentions him as an architect, and says he was the most ingenious part of garden-
ing, not ignorant in mathematics, and with some pretensions to astrology. He afterwards became a partner with Lucie, Field, and London, in the Raising Providence Nursery.

1. kennie of Rosehaugh in Abergenee, one of the earliest Scotch gardening authors.

2. Themes, wherein he is annexed, the Gardener's, Kalenda. Edin. 1683, 4to.

1684. Bobart, Jacob, curator of the botanic garden at

1685. Temple, Sir William, a statesman of de-

1. cent Eminence, and a miscellaneous writer, was born in London in 1628. He was ambassador for many years at the court of Holland, and there ac-
quired his knowledge and taste in gardening. He introduced some good sorts of grafted figs, and one sort of nightshade still bears his name; he
had an excellent walled garden at Sheen in Surrey, in which his contemporary Evelyn says his trees were most extensively planted. He died at Mose-

1. Park near Farnham in Surrey, where he died in 1698, and his heart, by his desire, was buried in a silver urn under a sundial in the garden. He was warmly competed and rewarded, and declared one of the greatest pleasures in life to be "such a liberty of liberty, as to be able to walk at one's pleasure and chance; and

1695. Scoto, Nicholas, of Dunblane, F.R.S., a ma-

1. thematisch, was born in 1644. He studied at Geneva, after which he settled at Utrecht as a tutor, but was there suspected of Spinoism.

1687. He came to England, where he taught mathematics, was tutor to the Marquis of Tavistock, and had a patent for jewel-watches; but when the French prelates made their appearance, he joined them in the conspiracy against the English king, and died in the pillory in 1716. He died at Worcester in 1755.

Some of his papers are in the British Museum.

1. Fruit Trees. With plans for ordering their sites, or A Way to build Walls for Fruit Trees, whereby they may re-

cell their buds and flowers ordered, &c. By a Member of the Royal Society, Gent. With Plates in Colours.

This is a very ingenious and scientific work, in which the advantages arising from the app of the rays at right angles are ma-

1. thematically and optically demonstrated.

1699. London and Wise, nurserymen and garden-

1. architected the most magnificent ones of the end of the eighteenth and beginning of the eighteenth century. George London was apprenticed to Rose, the royal gardener, and sent by him to France to study the gardens of Versailles. In 1699, when he returned he was made head gardener to Dr. Compton, Bishop of London, and at the beginning of the revolution, superintendent of the royal gardens, at a salary of 2000l. a year. He was a man of singular activity; and it is said he never left his house for a single day, and took a tour of the places at which he had concern, used to ride, at an average, sixty miles a-day, which at last overtook his health after a fort-

1. night's illness, in 1717.

The Complete Gardener: or Directions for Cultivating and right Husbandry. London, 1717. King Gardner's Almanack; or the Gardner's Calendar, directing what is to be done every Month in the Year, and the number of days the sun is to be seen in the heavens, comprehendedly abridged, and made of more use; with very considerable improvements. By George London, and Henry Wise. Together with a gardener's Guide to the Nobility and Gentry. By J. Evelyn, Esq. Lond. 1717. 4to.

1704. Dictionarium Rusticum; or, a Dictionary of Husbandry, Gardening, Trade, and Commerce. 2 vols. 8vo. with Cuts.

1706. Dictionarium Rusticum; or, a Dictionary of Husbandry, Gardening, Trade, and Commerce. 2 vols. 8vo. with Cuts. Most probably a trans-

1. lation from the French.

1707. Fletwood, William, successively Bishop of St. Asaph and Ely, and much admired as a popular preacher. Fletwood was born in 1655, published a great number of sermons, and other works, and died in 1723.

Caractories of Nature and Art in Husbandry and Garden-

1. ing. Lond. 1707. 4to.

1707. The Whole Art of Husbandry, in the way of managing and improving of Land.

1712. Addison, Joseph, was born at Milton in Wiltshire, and, when a youth, was educated at Westminster School, and at Oxford; he addressed some verses to Dryden at the age of twenty-two; obtained a pension of 300l. a-year; and, in 1722, on the continent for three years; returned and assisted Steele's

1. Tatter and Spectator; married the Countess-Dow-

1. ager of Warwick in 1716; became secretary of state; and was at the time of his death in 1717, the wife of a man who had died in 1717 at Holland House, Kensington, leaving only one daughter, who died unmarried in 1757.

1. On the Utility of the Sciences of the Imagination and Man-

1. nature. (Published in the Spectator, No. 141.)

1717. Dryden, John, written the "Natural Style." (Ibid. No. 47.)
1714. Lawrence, or Lawrence, John, M.A., an eminent naturalist, admitted of Clare-clo, Cam- bridge; and, on the 27th of June, 1730, was presented to the rectory of Yor- collapse in Northamptonshire, in 1760; where in three years he improved a garden of twenty-two years standing, and is said to have produced some of the choicest fruits. In 1721 he was presented to the rectory of Bishop Wearmouth, county of Durham, where he died in 1732. He is described as a man of singular ingenuity, disposition, and taking great pleasure in presenting a rich dessert of fruit to his friends. He was fond of gar- dening, and considered it as a recreation particu- larly adapted to his condition. He had a certain kind of exercis, being ad ruborem, non ad sudorem; such an exercise as studious men require; he considered it as much more than blasting in fine, the healthy medium." The Clergyman's Recreation: showing the Pleasure and Profit of Gardening. London, 1756.

1716. Switzer, Stephen, a seedsman and artist-gard- ener. To be addressed "At the Flower-pot over against the Court of Common Pleas in Westminster Hall; or at his garden in Millbank, Westminster." He is said to have been brought up under London and Wise. He appears to have been well educated for his time. He lived, and was, in that respect, so little is known of his history. He died in 1745. 1. Iconographia; or the Nobleman, Gentleman, and Gardener's Entertaining Observations for the Amusement of a Country seat into rural and extensive Gardens, Parks, Pad- docks, Fruit-Trees, and Flower-Gardens; with a great variety of Copperplates, from the Author's Drawings. London, 1729. 2. The Practical Fruit Gardener. London, 1724. 3vo.

1718. Bradley, Richard, F.R.S., a popular writer in the horticultural and agricultural circle. He was the in- dustry, author of various treaties in natural history, husbandry, &c. and Professor of Botany at Cam- bridge. According to Professor Martyn, "he was chosen into that office November the 8th, 1754, by means of a pretended verbal recommendation from Dr. Sherard to Dr. Bentley, and pompous assurances that he would procure the university a public bot- any, and a permanent botanical garden. He was universally interested. The vanity of his promises was soon seen, and his total ignorance of the learned languages known. In 1757 it was observed that he had got him out of his professorship; and he died in the latter end of 1759. It may seem strange to assert, that the translator of Xenophon's Economics did not under- stand a single word of Latin. If Dr. Bradley- bey's being then a popular name, he was paid by the booksellers for permitting them to insert it in the title." He first made himself known to the public in 1754, when he published the twenty-ninth volume of the Philosophical Transactions; one On the Motion of the Sip in Vegetables; the other, Micrographical Observations on Vegetation, and on the quick Growth of Mouldiness on Melons. From this time to his death he published two volumes in folio, four in quarto, and nearly twenty in duodecimo. His System of Agriculture besides other publications on natural history and the arts, Though Bradley's writings do not abound in new discoveries, yet they are not destitute of in- terest, and they contain much of the best advice to the temporary gardeners and from books. He was an advocate for the circulation of the sap, and made several new observations on the sexes of plants, in consequence of the production of hybrid species, by which he added strength to that doctrine. He wrote instruct- ively on the germs of trees, on bulbs, on grafting, and on the making and keeping of cuttings. He had many varieties of trees, and double flowers; and on the whole, his writings, coinciding with the growing taste for gar- dening, contributed greatly to the production of excellent improvements. His husbandry, contributed to excite a more philosophical view of these arts, and diffuse a gen- eral and popular knowledge of them throughout the Kingdom.

1. The History of Succulent Plants, with their Descrip- tion and Culture. In five volumes. 1715. 4vo.

2. New Improvement of Planting and Gardening, both Philosophical and Practical. 1717. 8vo.

5. A new Improvement of Planting and Gardening, both Philosophical and Practical, exhibiting a Particular Account of Water- setzen, Salt, and Generation of Plants; with other Discoveries never heretofore published. The Thoughts on the Improvement of Forest-Trees, Flower-Gardens, or Paterners; with several hints where-by more Designing of Garden Plants may be made in one year than can be done by all the knowledge of other men. It is Roger's saw, now added, the Gentleman's and Gardener's Calendar. The water, or Mist- Flower Plate. London, 1718. 4to.

6. The Monthly Register of New Experiments and Observa- tions. The First Number was published on the 19th of April and May 1722; wherein is explained, 1. The Method of potting Herbs, Flowers, and Fruits, to Perfection in the Spring; with new Inventions for the Propagation of the Fruit, and the Riveting of Fruit, &c. 2. An Account of transplanting Fruit-Trees, and Fruit-Trees, of any thickness, in the Summer season; so that gentlemen may make complete Plantations in the open ground, if they had been able to do so many years. Also a New Method for the Improvement of Tulips. The second edition ; to which is added, 3. An An- nals for some Observations lately made against the thermal of the Sap, mentioned in the Chapter of the Improvement of Tulips, in the first Edition. London, 1722. 8vo.

6. A General Treatise of Husbandry and Gardening, con- templating the different Productions of the World, useful for the Improvement of Land; with an Account of such extraordinary Inventions and Natural Productions as surpass those of Artificial and Universal learning. With variety of curious Cuts. Svo. 1725. 2 vols. 12mo. On Agriculture and Gardening, the second part of the second year, is inscribed to the Earl of Burlington, whose palaces and gardens give an example of his disting- uished taste, who is an intimate friend in all, among the most distinguished of the new Celt's; in writ- ing articles, "Observations concerning Vineyards and their Cultivation," part of the first part of the first Edition. The celebrated vineyard, it is stated, contains six acres of vineyards and 600 hundred pears, and is insured for 6000. He was told, also, that in 1722, there were still superior vines at Mr. Fairchild's at Hoxton, and at Hadley. London, 1725. 8vo.

8. A Philosophical Treatise of Agriculture; or, A New Method for increasing the variety of Trees, Shrubs, and Flowers; being a very curious work, enriched with many curious Cuts, and containing many Sorts of Trees and Plants; and for fertilising the most stubborn Solis. By G.A. Agricola, M.D. and Doctor of Philo- sophy. A Translation, with alterations and Remarks. Adorned with Cuts. The whole revised and augmented, by the Author of this Country; and confirmed this new Method. 1725. 8vo.

8. Botanical Dictionay, for the Use of the Curious in Botany; containing 1725. 2 vols. fol. every kind of plant. It is be- lieved, the first attempt of the kind in England.

10. The Vineyard: being a Treatise showing, 1. The Nature of Vines, Propagation, Manuring, Pruning, and Dressing and Direction of Vines, 2. Proper Directions for Drawing, Pressing, and others; in London, 1725. 8vo. of Viticulture, 3. An Easy and Familiar Method of Planting and Raising Plants; containing several useful Cuts. 1726. 8vo.

12. The Gentleman and Gardener's Calendar, directing what is necessary to be done in every Month in the Year, in the Kitchen Garden, Fruit Garden, and Nursery; Manage- ment of Green Houses, and other Places, points with Directions for the making and ordering Hou Grounds. This work, or the treatise of Huskard on the Artificial System of Vegetation; illustrated with many Observations and Experiments, formerly published in a Frenc and other Languages, and translated into Eng- lish, with Additions, and Alterations; in Four Parts. 1726. 8vo.

18. Taylor, Peter, Esq., son of John Evelyn. The Lady's Recreation; or the Third Last Part of the Art Gardening improved. Lond. 1717. 12mo.

20. Thome, commercial gardener at Hoxton, where he had an excellent vineyard, and was one of the principal nurseries and florists of the time. He first made himself known by a Essay in the Royal Society's Transactions (vol. xxxii, p. 127) on the different and sometimes contrary motion of the sap in plants," and assisted in expe-
riments on vegetable sexuality. He died in 1730, and left funds for a botanical sermon, which is deli-
vered annually on Whitson Tuesday, at St. Leon-
ard's Shoreditch; it was preached for many years by
the Rev. Mr. Ellis, of Merchant Taylors' school, and
published in 1739, and has since been continued by the Rev. Mr.
Ellis, of Merchant Taylors' school, who receives three guineas out of the funds left by Faithful for con-
tributions to the Gardeners' Dictionary.

The City Gardener; containing the Method of Cultivating such Plants as are necessary for the Grounds of Families, and Thriving in the London Gardens. 1729. 5vo.

1724. Miller, Philip, F.R.S., a celebrated botanist and gardener, was born in 1692. He married
Ellis, of Merchant Taylors' school, who receives three guineas out of the funds left by Faithful for con-
tributions to the Gardeners' Dictionary.

The City Gardener; containing the Method of Cultivating such Plants as are necessary for the Grounds of Families, and Thriving in the London Gardens. 1729. 5vo.

And it con-

bursed, Species, according to the present Practice of the most skilful Vigneron in the World. Together with New Experiments for Propagating and Improving, from real Practice and Ex-
periences, Horticulture, and Nursery. Also as for performing the practical Parts of Agriculture; including the Management of Vineyards, with the Methods of Testing the Nature of the different fruits, and their effects on the human System. The ninth or Professor Martyn's edition, is distinguished by the arrangement of the matter, and the completeness of the enumeration of the different sorts of plants; all those indicated which are to be found in the fourteenth edition of Linnaeus's Systema Vegetabilium, 1753, are described. In the fourth edition, he added several...
1732. Anon. A treatise concerning the best methods of pruning Fruit-trees, also the Method of Pruning Timber Trees, and also a Discourse concerning the Improvement of the Potato. London. 8vo.

1732. The Flow'rs of the Garden displayed, together with the Descriptions of most the Beautiful Flowers, with the description and use of some four hundred sorts of plants. Method of ordering.

1732. Furber, Robert, of Kensington, nurseryman, who published a number of separate prints of all the different sorts of Fruit-trees that had been brought into this country. His nursery is now in the possession of Messrs. Malcolm and Co.

1732. A catalogue for every month in the year, in fol. 12 Plates.

1732. An Introduction to Gardening, or Guide to Gentleman and Ladies in furnishing their Gardens, being several useful Instructions in the most approved Methods of their culture.

1732. More, Sir Thomas. A Treatise for gentleman and Ladies, or the Art of raising Flowers to grow in the depth of winter, also the method of raising Sissingett, Cucumbers, etc., at any time of the year.

1732. Furber, Sir Alexander, of Stanhope, author of some political works relative to Scotland.

The nature and method of Planting, Manuring, and Dying a Garden.

1733. A Lady. Merlin: A Poem; humbly inscribed to his Majesty. To which is added, The Royal Hermitage, A Poem. Both by a Lady, with several curious representations both of the Cave and Hermitage. 1733. 8vo.

1733. Furber, Little Gaddesdon, near Hempstead in Hertfordshire, author of Complete Husbandry, and other farming works.

An Essay of the most approved Methods of improving different lands with proper timber. Lond. 8vo.

1734. Anon. A Compleat Gardener's Monthly Calendar, shewing the best and most easy Method of raising and cultivating every sort of Seed belonging to a Kitchen Garden. Likewise for laying down of sowings of Berries, Mast, and Seeds, of Evergreens, Forest Trees, and such as are proper for Planting, with Directions for laying down. Written at the command of a Person of Honour. Lond. 8vo.

1734. Anon. An Essay upon Harmony; as it relates chiefly to Situation and Building. Svo. 1739.

1740. Gray, Christopher, a nurseyman at Fulham, who published with many other works, a curious treatise of botanists of his time, and the first who received the magnolia grandiflora from America, and propagated it extensively.

1740. Kane, William, and Shrubis which are prepared for sale by Christopher Gray, Nurseyman at Fulham. 1740.

1742. Furber, Adam's Luxury and Eve's Cookery, or the Kitchen Garden displayed. Svo.

1744. Watton, William, M.D. F.R.S. was born in London, in 1715, educated at Merchants' Taylor's school, and afterwards became a publican and a seaman.

He made discoveries in electricity, for which he obtained the Copley medal, and was honored with the title of Sir William, by several universities.

He died May 10, 1787. Besides papers in the Philosophical Transactions and the London Medical Observations, he wrote An Experiment on ice-volatile for the Smallpox.

1. On the Culture of Mushrooms.

1741. Anon. The Compleat Florist. 8vo. It consists of 100 copperplates and 170 figures, colored and hand labor.

1748. Anon. Catalogue of Hot-house, Green-house, Hardy, and Herba-

1749. Dickinson, James and Co., nurserymen and seedsmen, at St. James's. 8vo.

1750. Bichham, George. The Beauties of Stone, with cuts. 8vo.

1753. Anon. The Kitchens and Flower garden complete, in four sheets.

1753. Coventry, Francis, was born in Cambridge, and educated at the Magdalen-college, Cambridge, where he took his master's degree in 1752, and entered into orders. He died in 1759, having just before been presented to the donative of Edge- worth, where he was勾forster, a military at Culloden, and died a poetical epitaph to the honorable Wilmot Vaughan.

1753. Rocque, Bartholomew, a florist of Walham Green; author of some agricultural works: a great and valuable set of engravings, begun for the Duke of Ancaster, and from the engravings of these peaks of the field, he is said to have sold his portraits of persons, probably the father, who had a vineyard planted in a common field, from which he has drawn his years; and although the ground was flat, the wine was as good as that of Orleans and Auxerre.

1754. Justice, James, Esq., F. R. S., one of the principal clerks of session, or civil court of law, in Scotland. His father was a merchant and dealing with the Dutch, imported flower-roots, which it has been said first gave the subject of this memoir a taste for gardening. He had a villa and large garden at Daldike, in which he spent his fortune, in gardening pursuits, and was obliged to dispose of the property. Here, he practiced for thirty years; went twice to Holland to study the culture of bulbs, and returned to Italy; and satisfied the most learned societies in Britain of his practice and knowledge of the culture of fruit and vegetables. He was of an ardent temper, grew no person, but should be considered as a gentleman who bestowed more liberality upon improvements in gardening than I did, for the truth of which I can appeal to many of my countrymen.

He died about 1762 or 3.

2. A new edition, entitled, The British Gardener's Director, chiefly adapted to the Climate of the Northern Counties: containing the most curious instructions in the several Parts of Pleasure Gardens, and in the Nurseries, Green-house, and Shrub house. By Mr. Stru, one of the Royal Medical College of Session. Edinburgh. 1764. 8vo.—The Advertisement, dated 1764, is prefixed to this work; and a letter, written by Mr. Stru, in an answer to the Notice of the Gentleman's Gardener's Director. It appears that the gentleman was not convinced of the truth of the Advertiser's assertions, and gave reason to think he intended to have laid before the public his arguments and truly valuable work, founded upon reflection and experience.

1764. Anon. An Essay in the Cabi, and very different from any of the others.

1765. R—— S—— 8vo. Gentleman. This work, or Country Gentleman's Reformation; being the Kitchen, Fruit, and Flower-Garden, dis-
Hill was excluded from some nobleman's gardens for having carried off several valuable plants.

A short account of his life is contained in a work called Gardeners, published at Edinburgh in 1773, and his lady, Lady Jane Hill, published An Account to the Public, setting forth the consequences of his Accretions. This work is a fine paper, and a good

1. A Method of raising Trees from the Leaves. By John Hill, M.D. 1756. under the name of the gardens of
5. An Account of a Stone, which on being watered produced a flower. London, 1758. 8vo.
7. The Propagation and Production of Prolific Flowers, with the Culture at large for raising Double from Single, and Prolificous from the Double. Lond. 1759. 8vo. Plates 7. 24s. 6d.
8. The gardens of Dr. Hill. London. 1759. 8vo.
9. The gardens of Dr. Hill. London. 1769. 8vo.—a title prefixed to pamphlets published at different times.
11. Hill, Thomas, gardener to Lord Robert Manners, at Bloxholme in Lincolnshire, afterwards a member in Kent of a Breeder of Gardeners. He wrote on horticulture, and the improvement of barren lands in Aberdeenshire, of which county he seems to have been a founder. He published several works, and his papers came into the possession of—Meander, gardener to the Duke of Northumberland, who published them from the Universal Gardener.
12. The Trees on Fruit Trees. An original work, valuable for its mode of training trees.
13. An Essay on the Cult and Cold of Hot-houses. 1757. Chambers, Sir William; an eminent architect, was born in Sweden 1726, but his ancestors were of British origin. He was brought up at the age of two years, and placed in a school at Rippon. His first entrance into public life was in the capacity of supercargo on the Swedish trading ships, by which he made one voyage to China. On his return he quitted the sea, and applied to architecture, under the patronage of Lord Bute, by whose influence he was enabled to get into the service of the late king, then Prince of Wales. His first employment as an architect was in building a villa for Lord Boscroft at Rochampton, after which, he was employed in the building of gardens at Kew, where he introduced the Chinese ornaments. In 1771 he was honored with the Swedish order of the Polar Star, and in 1775 appointed to conduct the building of the Royal Palace at Stockholm. This is the only beauty of the royal society, and a member of that of antiquaries; besides which he held the places of architect to the Grand Lodge of Scotland, and of works, and treasurer of the royal academy. He died in 1765, aged 69.
14. Designs for Building Chinese Gardens, Furniture, Dresses, Machines, from the originals drawn in China; to which is annexed, A Description of their Temples, Hospitals, &c. London, 1777. 8vo.
15. Plans, Elevations, Sections, and Perspective Views of the Gardens at the Royal Palace at Kew, to which is added a Catalogue of all the Trustees, Parents, and other important subjects of the time. By T. Peto, a royal 1757. Thompson, John, a commercial gardener at Newcastle upon Tyne.
16. A Complete Body of Planting and Gardening, containing all the latest improvements in the art, for the use of the gentry and planters. London, 1777. 8vo. 4d.
18. Anon., erroneously attributed to Nicholls (Anon.) and to John Baynes, Sir John Baynes, after the death of
19. The following works are reprinted from the first and second editions of
20. Asper, Joseph, D.D., Professor of poetry in the university of Oxford, author of an essay on Pope's works, Critic, and other well known and esteemed works. He was the friend of Lord Walpole, and allowed to him for his taste in gardening. He was born in 1638, and died in 1678.
22. Anon., erroneously attributed to Nicholls (Anon.) and to John Baynes, Sir John Baynes, after the death of
23. Asper, Joseph, D.D., Professor of poetry in the university of Oxford, author of an essay on Pope's works, Critic, and other well known and esteemed works. He was the friend of Lord Walpole, and allowed to him for his taste in gardening. He was born in 1638, and died in 1678.
24. Thompson, John, a commercial gardener at Newcastle upon Tyne.
25. Asper, Joseph, D.D., Professor of poetry in the university of Oxford, author of an essay on Pope's works, Critic, and other well known and esteemed works. He was the friend of Lord Walpole, and allowed to him for his taste in gardening. He was born in 1638, and died in 1678.
26. Thompson, John, a commercial gardener at Newcastle upon Tyne.
1760. Anon. Adam armed: or an Essay endeavouring to prove the Ad-
variances of Improvements the Kingdom may receive, and the Inconveniences and Impediments it may avoid and re-
new, is a well-ordered and judicious Charter for Incorporating and Resolving the Professors of the Arts, and other Persons of Knowledge, by the Master and Company of the same. Fol. no date ; supposed about 1760.

1762. Home, Henry, commonly called Lord Kaimies, from his official legal situation; an eminently learned philosopher. New edition, with many corrections. Drawn after the original manuscript, and published by the Master and Company of the same. Fol. no date; supposed about 1760.

1763. Wheeler, James, a nurseryman at Gloucester, to whom this book was carried on by his two daughters, who separated some years ago, and it is now carried on by one of them.

The Botanist's and Gardner's New Dictionary; containing the Names of all the Ornaments, Genus Characters, and Specific Distinctions of the several Plants cultivated in England, ac-
cording to their botanical classification, with their introduction to the Linnean System of Botany. Lond. 1763. 8vo.

1764. Dodstey, Robert, an ingenious English poet, minister, bookseller, and writer on gardening; was born in Nottinghamshire, 1705.

A Description of the Leasowes, the Seat of William Shon-
ston, near Stratford-upon-Avon, as given by a Plan. Lond. 1763.

1764. Museum Rusticum, a periodical work, containing various papers on planting and horticulture. New edition. Drawn after the original manuscripts, and published by the Master and Company of the same. Fol. in 6 vols. 8vo.

The Museum Rusticum was succeeded by a similar work in 1765, entitled De re rusticâ, completed in 4 vols. 8vo. in 1770. It passed into the hands of Thomas Wright, Esq., a distin-
guished gentleman, celebrated for his taste in landscape-
gardening; born in Shropshire, 1714, died 1763.

Description on Landscape-Gardening. In his works collected after his death, in 5 vols. 8vo. Lond. 1765.

1765. Abercrombie, John, son of John Abercrombie, who was immortalized in the nursery-grounds of the City of Edinburgh; and was in the habit of supplying the markets of that city with vegetables.

John Abercrombie, our author, was born in 1726; and at the age of thirteen years settled in Edinburgh, where he lived. He afterwards had a garden and nursery at Hackney, whence he sent his goods to Spitalfields Market; and the profits of his business enabled him to sup-
port himself in such comfortable and genteel condition. At this crisis, some time about 1770, Mr. L. Davis, an eminent bookseller of London, accompanied by Dr. Oliver Goldsmith, having previously ordered a handsome book from his printer, Hackney, was surprised Abercrombie with an invitation to dine with them and view in the first place, the groundworks of his nursery; secondly, the business he was engaged in; and lastly, the general character of his materials; being revised, and the style improved by Dr. Gold-
smith. This celebrated writer, however, did not partake of the undertaking: after the pages had been handed to him by the humble gardener, then an inexperienced writer, and anxious to have his luxuries pruned, the doctor said, as an apology to the bookseller for returning the MS. unrevised, that Abercrombie's style as suited to the subjects of which it treated. Abercrom-
bie, however, frequently lamented, and the public often heard, that this laudable and curious and elegant writer did not fulfilled his engagement.

Abercrombie's first work was entitled Every Man his own Gardener, which had a rapid sale; and the second, entitled A catalogue of his yearly profits being more than 2000l., he was induced to neglect, and soon after to give up, his nursery; and to enter upon a course of au-
thorship on horticultural subjects.

Every Man his own Gar-
dener, the diffluence of Abercrombie induced him to affix to the title-page the name of Mawe, who was gardener to the Duke of Leeds. After the first edition, the second, entitled A catalogue of his yearly profits being more than 2000l., he was induced to neglect, and soon after to give up, his nursery; and to enter upon a course of au-
thorship on horticultural subjects.
so respectable a performance should be accompanied by this tone of distaste.

2. The Universal Gardener and Botanist, or a General Direction for Cultivating and Botanizing, according to the Linnean System, every Tree, Shrub, and Herbarious Plant that merits culture, &c. Lond. 1789. 3 vols. 12mo.

3. The Garden Mushroom, its Nature and Cultivation, exhibiting Points of Notice for raising every useful Fruit-tree and Fruit-bearing Shrub. Lond. 1779. 8vo.

4. The Cultivation of Fruit-trees, comprising the most approved Methods of planting and raising every useful Fruit-tree and Fruit-bearing Shrub. Lond. 1779. 8vo.

5. The White Wall-tree Pruner, &c. Lond. 1780. 8vo.

8. Daily Assistant in the Modern Practice of English Gardening; containing Rules for the Complete Management of the Kitchen Garden, raising all early Fruits, the earliest apples, &c. Lond. 1789. 12mo.

11. The Gardener, Florist, &c., or, Companion of General Gardening; a Descriptive Display of the Plants, Flowers, Shrubs, Trees, 

12. The Hot-house Gardener, or the General Culture of the Pine Apple, and the Methods of Forcing early Grapes, Sandal woods, &c. Lond. 1790. 3 vols. 12mo.

13. The Gardener's Pocket Journal and Annual Register, in a Concise and Useful Display of the State of General Gardening throughout the year. Lond. 1791. 12mo.

14. A New Edition of the Practical Gardener revised, with considerable Improvements. To which is added, a Letter to Sir Abraham Hume, Bart. 12mo. 1816.

15. A new improved Gardener's Complete, or Horticultural Calendar, containing the latest Improvements in Horticultural Practice. To which is annexed, on a plan never before attempted, a full Account of the Wilson and Darwin Collection of Plants, &c. given to the University of Cambridge from an original Manuscript of J. Abercrombie, the whole revised and corrected by Dr. De Candia. Lond. 1817.

17. Lightoller, J.,—a London architect.

The Gentleman and Farmer's Architecture, being Plans for building Farm-houses, with Pictures, Greenhouses, &c. on 52 plates, in folio.

18. Locke, John, one of the greatest and most eminent Philosophers; born at Wrington, Somerset, in 1632; author of numerous works; had a fine seat at Norbury Park in 1704. Observations upon the Growth and Culture of Vines and Olives, the Production of Silk and the Preservation of Fruits, &c., &c. Lond. 1743. 4to. The whole included in the following list:—

19. Anon. The Rise and Progress of the present Taste In planting pleasurable trees, &c. Lond. 1765. 8vo. The whole consigned to the press of the present Earl of Shaftesbury. Lond. 8vo.

21. Anon., or the True Pine Apple, in which the whole Culture, Management, and perfecting this most excellent Fruit is laid down in a clear and explicit Manner. To which is added a few common Raisins, &c.

22. A New Painted Garden, containing the most curious and elaborate edifices, &c. With a Copper-plate, exhibiting at one view the several Aspects for planting and raising all kinds of Trees, Plants, and Flowers. In 60 numbers, small folio, compiled in 1771.

23. Anon. The Gentlemen's Library, or, a General View ofAntiquities, but chiefly known as the inventor of the dendrometer.

24. Treatise on the Dendrometer, a new invented Instrument for the more certain and ready Measurement of Standing Timber by Inspection only; for facilitating the practical operation of Kindling, as well as of Lumbering; &c. Lond. 1788. 12mo.

25. Gardon, James, the Practical Gardener, and Gentleman's Directory for every Month in the Year, with particular Directions for raising Mushrooms. To which is prefixed, an Essay upon Vegetables, Specimens of Hard Things, &c. With a Copper-plate, exhibiting at one view the several Aspects for planting and raising all kinds of Trees, Plants, and Flowers. The whole consigned to the press of the present Earl of Shaftesbury. Lond. 8vo.

26. Poulet, Anthony, Esq., gardener to George II. The Royal Gardener; or, complete Calendar of Gardening for every Month in the Year. To which is added, many curious and so contrived as to exhibit, in a clear and comprehensive manner, the business to be done in the Flower, Fruit, and Kitchen garden at all times of the year, according to every particular season. Lond. 1769. 8vo.

27. Trees, Adam, gardener to J. Sutton, Esq., at New Park, near Devizes, in Wiltshire.

Treatise on the Ananas, or Pine-Apple, containing plain and easy Directions for raising the same, from seed to fruit and in much higher perfection than from the store. To which are added, full Directions for raising Melons, Peaches, &c. Lond. 1780. 8vo.

29. Ellis, John, Esq., a distinguished Naturalist; a native of Hampshire; celebrated for his discovery of the animal origin of corals. He wrote a variety of tracts, and numerous papers in the Transactions of the Royal Society, the Transactions of the British Association, the Transactions of the Royal Society of Edinburgh, &c.

30. Directions to Voyagers for bringing over Plants, &c. from the East Indies, and other distant Countries, in a state of preservation. Lond. 1772. 8vo.

32. Historical Account of Coffee; and, with an Engraving, and Botanical Description of the Tree. To which are added, many Papers relative to its culture and use as an article of diet and of commerce. Lond. 1774. 8vo.

33. Description of the Mangosteen and the Braud Fruit, the first esteemed the most delicious, and the latter the most useful of all the Palm-climbing Trees. To which are added

34. B. 2

Stocks for multiplying Fruit-trees, with directions for laying out and managing Fruit-grounds. Lond. 1788. 8vo.

35. Gilpin, the Rev. William, M. A., an ingenious divine, born in Carlisle 1724, educated at Oxford; kept a shop for many years in the City of London, and afterwards became vicar of Boldre, in Hampshire, and prebendary of Salisbury, where he died in 1804. The whole of his tours and other works on the picturesque, well merit the study of the landscape-gardener.

1. Observations on the River Wye, and several Parts of South Wales, relative chiefly to Picturesque Beauty, made in the Summer of 1770. Lond. 1783. 8vo.

2. Observations and Picturesque Beauty, made in the year 1773, on several Parts of England; particularly the Mountains and Lakes of Cumberland and Westmorland. Lond. 1786. 8vo.

3. Observations chiefly relative to Picturesque Beauty, made in the year 1777, on several Parts of Scotland, particularly the Highlands of Scotland. Lond. 1788. 2 vols. 8vo.

4. Remarks on the Beauties of England and Wales, relative chiefly to Picturesque Beauty. Illustrated by Scenes of New Forest, in Hampshire; in 3 books. Lond. 1791. 2 vols. 8vo.

5. Three Essays, or a Discourse on Natural and Picturesque Travel; on Sketching Landscape. To which is added, a Poem on Landscape Painting. Lond. 1784. 12mo.

6. Observations on the Western Parts of England, relative chiefly to Picturesque Beauty. To which are added, some Remarks on the Beauties of the Isles of the Isle of Wight; 4 Plates. Lond. 1798. 8vo.

8. Observations on several parts of the Counties of Cambridge, Norfolk, Suffolk, and Essex; also several parts of North Wales, relative chiefly to Picturesque Beauty, made in the former made in the year 1769, and the latter in 1773. Lond. 1803. 8vo.

8. Mason, George, Esq., a classical scholar and critic; author of an Appendix to Dr. Johnson's Dictionary, and of some other translations and philological works. He lived chiefly at Stourhead, where he was connected with the Sun Fire Insurance Office.

10. A New Gardener's Dictionary, or, the whole Art of Gardening fully and fully, with some true and correct Proofs of cultivating all kinds of Trees, Plants, and Flowers. In 60 numbers, small folio, compiled in 1771.

11. Dicks, John, gardener to His Grace the Duke of Kendal, at Kendal, in Lancashire.

A New Gardener's Dictionary, or, the whole Art of Gardening fully and chiefly, with some true and correct Proofs of cultivating all kinds of Trees, Plants, and Flowers. In 60 numbers, small folio, compiled in 1771.
Directions to Voyagers for bringing over them and other vegetables. Lond. 1775.

1770. Hunter, Alexander, M.D. F.R.S. was born at Edinburgh 1735; settled as a physician at Gainsborough, at Beverley, and finally at York; author of various medical and surgical works, and of a cookery-book: died at York 1803.

New Edition of Evelyn's Sylva and Terrace.

1772. Trenchard, Esq., an amateur gardener, who derived his information chiefly from inspecting the commercial gardens near London.

1. The Planter's Directions for Foley Agriculture and Gardening, in which the advantages of introducing the Culture Garden in the Field is fully proved. Which is added, A Complete Chronological Catalogue of English Authors on Agriculture, Gardening, &c. Lond. 1769. 8vo.

2. The Universal Botanist and Nurseryman, containing Descriptions and Varieties of all the Trees, Nuts, Herbs, Flowers, and Fruits, Natives and Exotics, at present cultivated in the European Nurseries, Greenhouses, and Stoves, as described by modern Writers. Lond. 1774. and 4to. The Linnean System, and their Names in English. To which are added, A copious Botanical Dictionary, containing useful Catalogues and Indexes. Plates. Lond. 1774. 4 vols. Svo.

1772. Wheedley or Whetlesey, Thomas, Esq. of Norfolk, a member of the royal college of physicians, and an appendix, consisting of an Essay on the natural Situation of Gardens, originally published by Dodgson.

1773. Meader, James, gardener to the Duke of Northumberland at Sion House, and afterwards to the Empress Catherine at Peterhof, near Petersburg, was a very satirical writer, and wrote verses both on his friends and enemies.

1. The Modern Gardener, or Universal Calendar; containing Directions for the Opening of new Gardens, and Gardening, to be done either in the Kitchen, Fruit, Flower, and Pleasure Gardens, as likewise in the Greenhouse and Hot-house; with the Accounts of the several Works of performing the different works, according to the best practice of the most eminent Gardeners. Also an Appendix, containing Varieties and Descriptions of Grapes, Vines, Peach, Nectarine Trees, &c. in a new manner: never before published. Lond. 1773. 4to.

2. The late Mr. Hitt. Revised, corrected, and improved by J. M. Lond. 1771. 12mo.

3. The Planter's Guide, or Pleasure Gardener's Companion; giving plain Directions, with Observations for the proper Disposition and Situation of all the various Plants usual in a Pleasure Garden Plantation. To which is added, a list of Hardy Trees and Shrubux for ornamenting such Gardens. Embellished with twenty-six plates. Lond. 1774. Svo.

1772. Bouchter, William, a nurseryman at Comely Garden, near Edinburgh.

- Treatise on Forest Trees; containing not only the best Methods of their Culture hitherto practised, but a variety of new and ingenious. the result of many repeated Experiments. To which are added, Directions for the Disposition, Planting, and Culture of Hedges. Lond. 1771. 4to.

- A Poem in four books. Lond. 1779-82. 4to. A new edit. Corrected. To which are added, a Commentary and Notes, by W. Burgh, Esq. Lond. 1785. Svo.

1775. Pye, Mrs. Hampden. The Flower and Fruit Gardens in and about Twickenham (the residence of the Muse) descriptive of their Beauties, internal and external, with Directions for the planter and Companion for the gardener. Lond. 1773. 12mo.

1776. Ellis, Thomas, gardener to the Lord Bishop of Lincoln.

The Akenside's Pocket Kalendar. Lond. 12mo.

1777. Anderson, James, L.L.D., an agricultural writer of great versatility of genius, was born at Herndonstein, in the county of Edinburgh, 1730, on a farm which his parents had purchased for some generations, and which he was destined to inherit and to cultivate. He lost his parents at an early age, and was brought up by a preventive chemistry under Dr. Cullen, and soon leaving his farm near Edinburgh, took one in Aberdeen-shire of 1500 acres, which, after improving and cultivating for two years, he let, and enjoyed the fruits of it during the rest of his life. He settled after leaving Aberdeen in the neighborhood of Edinburgh, where he published the Bc, in weekly sixteen-pagers, which were extended to extenss.

In 1797 he removed to Isleworth, near London, where he published Recreations in Agriculture, six volumes, and his Description of a Patent Harietia, which was esteemed of the highest value.

a man of taste and genius, author of the Castle of Otranto, several papers in the World, &c.; he sat in parliament from 1741 to 1788, when he retired, and devoted his time to the improvement of his estate at Twickenham. In 1763 he succeeded his nephew as Earl of Orford, but never took his seat in the House of Lords. He died in 1768.  

On Modern Gardening, published in the Anecdotes of Painting; in a later edition of 1782 there are some additional notes.  

Various Remarks on Gardening occur in his correspondence with Mr. Massey, preserved in the Royal Horticultural Society, 1785.  

1751. Otranto, E. M. D. F. R. S., an eminent physician and poet, born at Elton near Newark, in Nottinghamshire, in 1731. Completed his medical course at Cambridge, where he resided the greater part of his life: but went to Derby in 1731, and died there in 1802. As a poet he is esteemed rather gaudy and fanciful; as a physician, he is apt to indulge in hypotheses; but possesses the great quality of being totally exempt from every kind of prejudice.  

He was a Pliny of Agriculture and Gardening, with the Theory of Draining Morasses, and with an improved construction of the Drill Plough. Lond. 1780. 8vo.  

1751. Palmer, Samuel.  

The Young Gardener's best Companion for the Kitchen and Fruit Garden. Lond. 12mo.  

1751. Lettsom, John, Cokely, M. D. F. R. S., an eminent physician and poet, born in London, was born on a small island called little Van Dyke, near Torbay, in 1744; died 1818.  

1. Hortus Uptonensis; or a Catalogue of Trees and Greenhouse Plants in Dr. Fothergill's garden, at his death. Lond. 1781. 8vo.  

2. Goyville; a Rural and Horticultural Sketch. Lond. 1785. 8vo.  

1753. Anon. Some thoughts on Building and Planting, addressed to Sir Matthew Bart. published in Dodsley's collection of poems for this year.  

1753. Bryant, Charles, of Norwich.  

1. Flora Dittonensis, or the History of Resident Plants, both Domestic and Foreign, in which they are accurately described; and their native countries, with their English names annexed. Lond. 1783. 8vo.  

2. A Dictionary of the Ornamentals, Shrubs, and Plants which are commonly cultivated in the Plantations of Londo-, and Stoves of Great Britain; arranged according to the order of the different kinds, and containing Descriptions of the Genera and Species, with the names proper to each. London. 1784. 8vo.  

1753. Falconer, William, M. D. F. R. S., physician to the general hospital, Bath; author of a number of medical works, and of Remarks on the Climate, Situation, and Nature of counties, the population, nature of food, and way of life; on the disposition and temper, manner and behaviour, intellects, laws and customs, forms of government, and religion of mankind. A most interesting work.  

1. An Historical View of the Taste for Gardening and Ornamental Trees among the Nations of Europe. The principal parts of this tract were originally printed in the Philosophical Memoirs of the Manchester Society, 8vo.  

2. An Essay on the Preservation of the Health of Persons engaged in Agriculture and Hunting: besides which he wrote Practical Observations on the British Grasses, and some papers in the transactions of the Linnean Society, of which he was a member. He died in 1759, and was buried at Battersea; after his death his lectures were published with colored plates.  

2. A Directory of the Botanical Magazine in 1787. A work which has met with great encouragement, and has done much to diffuse a general taste for botany. It is still continued by Dr. W. Beattie.  

2. Observations on Aphid, chiefly intended to show that they are the principal cause of Blights in Plants, and the sole cause of the Honey Dew. (Trans. Linne. Soc. XI. 72. 1802, post.)  

1754. Rodenhurst, T. A Description of Hawkstone in Shropshire, the seat of Sir Richard Hill, 1754. 12mo.  

1755. Anon. Miscellaneous on Ancient and Modern Gardening, and on the Scenery of the West Indies. Lond. 1755. 12mo.  

1756. Kyle, Thomas, gardener to the Hon. Baron Stewart of Moredon, near Edinburgh. One of the first gardeners in Scotland of his rank. His Treatise on the Management of the Peas and Nectarine Trees, either in forcing-houses or on hot and common Walls, Edin. 8vo.  

1755. Marshall, William, Esq., a native of Yorkshire, brought up to trade; was some years in the West Indies, but returned about 1775, and took a farm in Surrey; went down into Norfolk as agent to Sir Harbord Harbord's estate in 1770; left this situation in 1774, and went and resided at Stafford, near the seat of the Duke of Buckingham, in the county of Leicester, Warwick, Stafford, and Derby, where he remained till 1786, occupied in collecting materials for his celebrated work on the productions of his works. From this time, till about 1808, he resided chiefly in Clevely's Inn, London, in winter, and visited different parts of the country during summer. He was one of the first men, who, chiefly on the Earl of Bredalbane's estate at Taymouth, and partly also on the Earl of Mansfield's at Scone. He proposed arrangements for the tenant- able lands, and also the park and woody scenery on various estates; and finally retired to a considerable property he purchased in his native county, in the Vale of Cleveland, in 1796, where he died at an advanced age, in the year 1808. He was the author of little application, but of a strong and steady mind; and pursued, in the most consistent manner, from the year 1780 to his death, the plan he originally laid down; that of collecting and condensing the agricultural practices of the different counties of England, with a view to a general work on Landed Property, which he published in 1796. He did not live to complete; and a Rural Institute, in which he was supplanted by the Board of Agriculture.  

2. A Review of the Landscape, a didactic poem; also an Essay on the Picturesque; together with Practical Remarks on Rural Ornament. Lond. 1786. 8vo.  

1786. Brevo, Philip Le, M. A., chaplain to the Duke of Gloucester. About the time he published his work on the Vine, he took out a patent for "training all the sorts of fruit-trees on the ground," as suggested by Lord Bacon, and practised at the time the patent was taken out by F. X. Vispre, at Wimbledon, and subsequently at Chelsea. (See Specchey, Treatise on the Vine, 5vo. edition, p. 205.)  

1. A Description of certain Methods of Planting, Trimming, and Managing all kinds of Fruit Trees, Vines, &c. Lond. 1786. 8vo.  

2. Sketch of a Plan for making the Tract of Land called the New Forest, a real Forest, and for various other purposes of the first national importance. Stockhol. 1783. 8vo.  

1787. Browning, Robert, gardener to Sir Harbord Harbord, Bart. at Gunton, in Norfolk.  

A method to preserve Peach and Apricot Trees from the Effets of the Mists; and for keeping the red wine in a perfect state, in melon frames, and other insects which infest plants in stoves, and trees, and fruit-trees that have been opened. Lond.1780.  

1787. Vispre, Francis Xavier.  

1789. Emmmoreich, Lieutenant-colonel A., a German gentleman, author of a tract on his own pro- fession, and deputy-surveyor of the woods and forests under Mr. Robinson.  

The Culture of Forests; with an Appendix, in which the state of the Royal Forest in the last century, and for the red wine, in melon frames, and other insects which infest plants in stoves, and trees, and fruit-trees that have been opened. Lond.1780.  

1789. Graggel, John, a native of Germany, who came to England in the beginning of the eighteenth century, and after being some time under Miller, was gardener to James Vere, Esq. of Kensington-Gore. Afterwards he joined Thompson, a gardener, and Gordon, a seedsmen, in establishing a nursery at Mile-end. When Gordon died, the nursery became the sole property of Thompson, the present pro-
priest; and Greffier, soon afterwards, received from Sir Joseph Banks the appointment of gardener to the King of Naples, at Caserta. Here he laid out an extensive and beautiful garden, with exotic trees from the Hammersmith nursery. He was employed by Admiral Lord Nelson to look after his estate of Blenheim, and various native vegetation to lay out their grounds; he remained in his situation as gardener at Caserta during Murat's reign, and died there, or was in part murdered when he fell from his horse near his own house in 1810.

A descriptive Catalogue of upwards of 1100 species and varieties of Herbsaceous or Perennial Plants: divided into six convenient classes, with the names, magnitude, height and situation, time of flowering, color of the flowers, and native country. Printed for J. Forbes, for the decoration of Northern Borders, and the most ornamental Annals. Lond. 1793. 8vo.

3. The Botanist, F.L.S. A botanical draftsman and engraver to whom science is much indebted. He formed a rich museum of botany and mineralogy, and published different valuable works on the latter subject. He died 1797.

1. The Florist's Delight, containing six Coloured Figures, with botanical Descriptions. Lond. 1803. 4to.

4. Notes on the Effect of Watering Fruit Trees early in the Spring. (Hort. Trans. ii. 271)

1790. Brattle, W. Points for the Management of Hotbeds, and Directions for the Culture of early Cucumbers and Melons. To which are added, brief Instructions for Pruning Wall and Espalier Trees. Bath, 1790. 8vo.

1793. Forsyth, William, Esq. F.A.S., a native of Scotland, and Master of the Garden in the pleasure Grounds at Greenhagen in 1738; came to England in 1763, and was some time employed under Miller at Chelsea. He was afterwards gardener at Sion House, till Miller's removal in 1785, when he succeeded him as curator of the Chelsea garden; and at the death of the late Thomas Robinson, Esq. royal gardener at Kensington, in 1784, he was appointed to that situation. Here, finding himself, in an old worn-out state, he began a system of renovation by heading down, and renewing the soil, in which he was highly successful; and for discovering the ingredients of a composition which quickly produced a great change, he received a parliamentary reward. His works procured him the published admiration of Knight, M'Phail, Pontey, and others. He died in 1804, and left a son and a daughter, Mr. and Mrs. B. seedsmen, and author of a botanical catalogue, 8vo.

1. Observations on the Diseases, Defects, and Injuries in all kinds of plants, and of a count of a particular method of Cure, invented and practised by the Author. Lond. 1791. 8vo.

2. Treatise on the Culture and Management of Fruit Trees; in which a new method of pruning and training is fully described. Lond. 1804. 4to.

1791. Linnaean Society. Transactions of the Linnaean Society, vol. i. 4to.; vol. ii. containing the first six volumes containing the papers connected with gardening; such for example as: 1. Biographical Memoirs of Sir William Jones. 2. Notes relating to Botany, and collected from the manuscripts of the late M. Linnæus, Esq. F.R.S. and others. Lond. 1790. 8vo. On the supposed Effect of Ivy upon Trees, vol. ii. 27.

1791. Salisbury, Richard Anthony, Esq. F.R.S., a learned botanist, enthusiastically attached to that subject. Salisbury was educated at North Bierly and the university of Edinburgh. He had a fine garden (now a public nursery) at Chapel Allerton, near Leeds, and afterwards purchased the estate of the late Peter Collison, Esq., at Millhill, near London. He now resides in the metropolis, and is an active member of and contributor to the Horticultural Society.

1. On the Cultivation of the Polianthes Tuberosa, or Tube- rose; with its Botanical Description and Figure. (Trans. Hort. Soc.) vol. i. 1813. 8vo.

2. Observations on the different Species of Dahlia, and the best method of their cultivation. (Ib. 8vo. 1814.)

3. A short Account of Narcissi and Peaches naturally produced on the same Branch. (Ib. 1815. 8vo.)

4. Some Observations of the Red Doyenne Pear, with a Figure. (Ib. 1820. 8vo.)

5. Some Account of two new Varieties of Grapes. (Ib. 1828.)

6. On the Cultivation of Rare Plants. (Ib. 1861.)

7. Some Account of the Chinese General Jambos. (Ib. 1841.)

8. The National Garden at Paris. (Ib. Appendix.)

9. On the Vegetation of High Mountains; translated from a French Treatise on the same Subject, by Mr. M'Nab. (Ib. 1830. 8vo.)

10. Description of a Bank for Alpine Plants, by Mons. Thouin, habitué du Jardin des Plantes. (Ib. 1834. 8vo.)

11. On the Cultivation of the Monopous Conicus. (Ib. ii. 1815.)

12. Some Account of the Chiloeensis Serryfishlia, or Snow- berry, a fruit nearly allied to the Cranberry. (Ib. 1844.)

13. The Cultivation of the Gleditsia Jambos. (Ib. 1843.)

14. The beautiful Evergreen Shrub from China. (Ib. 1856.)

15. Description of Ornd's Apple. (Ib. 1857.)

16. Some Account of the Malus Pellucida, a beautiful

A Practical Treatise on Planting. Dublin. 8vo.

1794. Knight, Richard Payne, Esq., a gentleman of great horticultural attainments, and of much influence, being proprietor of a fine demesne and park near Ludlow, on which he built an elegant mansion from his own designs. After residing there many years, he gave up the management of it, to his brother, the celebrated horticul
turist, and now lives chiefly in London.

The Landscape, a didactic poem. 4to. plates. This picturesque and descriptive work on Landscape, a poetical treatise, sublimate naturally attached to the poet Mason; and a Review, by W. Marshall; the latter a very virulently produced. (Ib.)

1795. Banks, John, a native of Aberdeen; gardener for twenty years to Lord Hawkesbury (now the Earl of Liverpool), at Aldiscombe Place near Croydon. An excellent grower of pines and other evergreens, and of some tracts on Agriculture and the poor Laws.

1. Treatise on the Culture of the Cucumber; shewing a new and capital method of Cultivating that Plant, with full directions for the Management thereof, and the degree of Heat it requires on every Day of the Year, &c. To which are added, hints on the improvement of the Green-house. Lond. 1794. 8vo.

2. Hume's Reminiscences throughout the Year, exhibiting the safest and most improved Methods of Manuring, Digging, Sawing, &c.; the Nature of Earth, Water, Heat, Air, and Climate, best adapted for the Culture of Plants, and Production of Fruits, Flowers, and excellent Vegetables, in the forcing way; the Causes and Symptoms of Disease and barrenness in Trees of every kind, with means of Prevention and Cure. Lond. 1804. 8vo. A new and improved View of Mr. Forster's Treatise on Trees. Lond. 1794. 8vo. Price, Uvedale, Esq., of Foxley, near Here
dord. A gentleman and scholar of great taste;
enthusiastically fond of pictures, statues, and picturesque beauty in all objects and mental impressions; and who has greatly improved and beautified his country.

1. An Essay on the Picturesque, as compared with the Sublime and the Beautiful, and on the Use of Studying Picturesque Plants, with a View of improving Real Landscape. Lond. 1801.

2. A Dialogue on the Distinct Characters of the Picturesque and the Beautiful, in Answer to the Objections of Mr. Knight. Lond. 1802.

3. Letter to H. Repton, Esq. on the Application of the Prac
tice, as well as the Principles, of Landscape Painting, to Land
capital. Lond. 1803. Extract in the Essay on the Picturesque; to which is prefixed Mr. Repton's Letter to Mr. Tro			
trebell. Lond. 1804.

1794. Shaw, James, author of a Tour in the Ne			
ethlands.

Parts, Elevations, Sections, Observations, and Explanations of
Forcing-houses in Gardening. Whitch. Fel.

1795. Knight, Thomas Andrew, Esq. F. R. S. L. S, 
late president of the Horticultural Society. A dis
tribution of vegetable physiological and horticulturist to R. P. Knight, Esq. (See 1794).

2. Some Doubts relative to the Efficacy of Mr. Forster's Vitus, in the Practice of Forcing; to which is prefixed Mr. Repton's Letter to Mr. Trebrell. Lond. 1804.

5. Observations on the Grafting of Trees. (Phil. Trans. Abr
t. 35th. 1802.)

7. Account of some Experiments on the Ascent of Sap in
Trees. (Ib. 335. 1801.)

9. Experiments and Observations on the Motion of the Sap in
Trees. (Ib. 230. 1805.)

10. Concerning the state in which the true Sap of Trees is deposited during Winter. (Ib. 240. 1806.)

12. On the Formation of Fruits. (Ib. 258.)

15. On the Origin and Formation of Roots. (Ib. 169, 1802.)

16. On the comparative Influence of Male and Female Parts on the Growth of Plants. (Ib. 154. 1802.)

17. On the Fruits of Trees primarily impaired by Age. (Ib.
175. 1810.)

18. On the Causes which influence the Direction of the
Growth of Roots. (Ib. 299, 1811.)

19. On the Extent of the Expansion and Contraction of
Timber in different Directions, relative to the Position of the Natural Grain, in Different Trees. (Ib. 294. 1812.)

20. Introductory Remarks relative to the Objects which the Horticultural Society have in view. (Hort. Trans. 1. 1. 1806.)

21. Directions for Growing and Grooming the Vegetable of seeds. (Ib. 199, 1806.)

22. On the Inverted Action of the Alburnum Vessels of
Trees. (Ib. 351. 1812.)

23. On the Formation of the Bark of Trees. (Ib. 103, 107.)

24. Observations on the Secretion of Trees. (Ib. 80.)

25. On the Inconvertibility of Bark into Alburnum. (Ib. 103, 107.)

27. On the Causes which influence the Direction of the
Growth of Roots. (Ib. 299, 1811.)

28. On the Extent of the Expansion and Contraction of
Timber in different Directions, relative to the Position of the Natural Grain, in Different Trees. (Ib. 294. 1812.)

29. Introductory Remarks relative to the Objects which the Horticultural Society have in view. (Hort. Trans. 1. 1. 1806.)

30. Directions for Growing and Grooming the Vegetable of seeds. (Ib. 199, 1806.)

31. On the Inverted Action of the Alburnum Vessels of
Trees. (Ib. 351. 1812.)

32. On the Formation of the Bark of Trees. (Ib. 103, 107.)

33. Observations on the Secretion of Trees. (Ib. 80.)

34. On the Inconvertibility of Bark into Alburnum. (Ib. 103, 107.)

35. The Opposes or Alburnum of Trees, (Phil. Trans. 178.)

36. On the Advantages of Grafting Walnut, Mulberry, and
Chesnut Trees. (Ib. 60.)

37. On the New Method of Rooting Fruit Trees. (Ib. 70.)

38. On the advantages of Forcing-houses for Grapes. (Ib. 79.)

39. On the construction of Forcing-houses for Grapes. (Ib. 78.)

40. On the Short of a new Apple called the Downton
Flippin. (Ib. 145.)

41. On the Advantage of the Onion. (Ib. 157.)

42. On the Improved Method of cultivation the Alpine Straw-
berry. (Ib. 158.)

43. On the New Varieties of the Peach. (Ib. 165.)

44. On the Horticultural Aspects of the Cherry. (Ib. 109.)

45. On Potatoes. (Ib. 157.)

46. On the new and judicious Mode of Budding. (Ib. 194.)

47. On the New Method of growing the Alburnum of late
Fruits. (Ib. 57.)

48. On the young and Early Varieties of the Potatoe. (Ib. 57.)

49. On the fruit of the Potatoe of the Hotbeds. (Ib. 254.)

50. A short Account of a new Apple called the Downton
Flippin. (Ib. 145.)

51. On the Advantage of the Onion. (Ib. 157.)

52. On the Superiority of the Autumnal Apple. (Ib. 157.)

53. On the Culture of the Potatoe in Hotbeds. (Ib. 211.)

54. View of the Theory of Vegetation. (Ib. 217.)

55. A Short Account of some Apples and Pears, of which
Grafts have been sent to the Alburnum of the Horticultural Society. (Ib. 226.)

56. On the Culture of the Potatoe in Hotbeds. (Ib. 211.)

57. View of the Theory of Vegetation. (Ib. 217.)

58. A Short Account of some Apples and Pears, of which
Grafts have been sent to the Alburnum of the Horticultural Society. (Ib. 226.)

59. On the Advantage of employing Vegetable Matter as
Manures in the Alburnum. (Ib. 254.)

60. On some Early Varieties of the Potatoe. (Ib. 244.)

61. On the facilitating of Estate from the Lovers of
Lettuce. (Ib. 255.)

62. On some New and improved Varieties of Grapes. (Ib. 255.)

63. On the Transplantation of Blossom-Buds. (Ib. 2.)

64. On an early Variety of Grapes from Amiens. (Ib. 103.)

65. On the proper Stock for the Moor Park Apricot. (Ib. 194.)

66. On the budding of peach-leaves. (Ib. 194.)

67. On the prevention of the Disease called the Curr in the
Potato. (Ib. 255.)

68. On the Culture of the Mulberry. (Ib. 68.)
turtled to England. He now directed his attention to drawing, architecture, and particularly landscape-gardening, for which last he obtained considerable employment. He died in 1818, leaving several sons, one of whom married the daughter of Lord Elton. Repton published some books on miscel-

naneous subjects, but his principal works are on landscape-gardening:
1. Letter to Vedale Price, Esq. on Landscape-Gardening. 1777.
2. Sketches and Hints on Landscape-Gardening; collected from the works of all observers, in the estimation of the different noblemen and gentlemen for whose use they were originally made: the whole tending to establish fixed principles; and forming a system of Landscape Dyalyses. Lond. 1755. folio.
3. Observations on the Theory and Practice of Landscape-Gardening, including some Remarks on Greek and Gothic Architecture. Lond. 1756. 2 vols. 4to. 1st edn. 1750. 4to.
4. The Villa Gardener, or Monthly Index of Work to be done in the Town and Villa Gardens, Shrubberies, Par
tains, Etc. 1758. 4to.
5. The Gardener's Kalendar; or, the Nurseryman and Forester's Guide in the operations of the Nursery, the Forest, and the Garden. Lond. 1760. 2 vols. 12mo. 1st edn. 1758. 4to.
6. Robinson, a London architect, nephew to Thomas Robinson, Esq. gardener to Geo. 4th. 1803. 4vo.
7. Observations on laying out the public Squares of London. (Literary Journal, 1803.)
8. Hints on the Forming and Management of Useful and Ornamental Plantations; on the Theory and Practice of Gardening, and the Improving of the Em- bulding Land from Rivers, or the Sea. Edin. 1804. 4to.
9. A Treatise on form ing, improving, and managing Cottage Gardens, in the choice of Plants, and in the arrangement of their different parts. This is approriate to every class of Purchasers. With an Appendix, containing an Enquiry into the utility and merits of Mr. Repton's Improvements of the National Gardens, as adapted by Nisbet and Nisbet, in their Series of Scenery and Natural Landscapes, for the use of Country Seats, and passages of Country in most parts of Great Britain, and by 24 engravings. Lond. 1805. 2 vols. 4to.
11. Remarks on the Construction of Hot-houses; pointing out the most advantageous Forms, Materials, and Conditions to be used in their Construction; with a Review of the various Methods of building them in foreign countries, as well as in England: with 3 plates, from Images of China, 1712. 4to.
12. Sketches of Carriuilline Hot-houses; with a Description...
of the various purposes in Horticultural and General Architectural Works. L. and London, 1818. 8vo.
3. A cognitive View of the common and curvilinear Mode of rooting Hot-houses. Lond., folio, 1818.
5. Observations on the Mode of cultivating the Pine Apple from its first introduction to Europe to the improvements of T.A. Howard, Esq. Lond. 12mo. 1821.
6. Moriarty, Mrs. Henrietta Maria, author of several novels.
8. Amos, Illustris, formerly a gardener and but if to a nobleman, and afterwards a farmer at Bourne, Lincolnshire, author of some works on the drill husbandry.
10. Dr. Johnson, Sir James, the Son of the Royal Society, was the son of William Banks, Esq. of Revesby Abbey in Lincolnshire, and born there in 1743. He received his education first at Eton, and next at Oxford, but left the university in the death of his father in 1761; and two years afterwards made a voyage to Labrador and Newfoundland. In 1788, he and Dr. Solander went with the Lieutenant Commander of the East India; in which year Mr. Jones narrowly escaped perishing by the frost, on the island of Terrn del Fuego. After his return he received the degree of doctor of laws at Oxford, and in 1792 undertook a voyage to Iceland and the Western Isles of Scotland. In 1778 he received the Order of the Bath, and was elected president of the Royal Society. In 1791 he was chosen a fellow of the college, but about two years afterwards his conduct in the Royal Society gave such offence to the scientific members as had nearly produced a schism; this temptation notwithstanding, was dispelled, and the president retained his seat without any further opposition to the end of his life. Sir Joseph, though afflicted for many years with the gout, continued his exertions for the improvement of agriculture, and the extension of natural history to the very last of his long and useful life. He died May 9, 1820. He has some papers in the Philosophical Transactions, and published a treatise on the professor of Wheat. 1st. An Attempt to ascertain the Time when the Potatoes (Solanum Tuberosum), was first introduced into the United Kingdom. By Dr. Richard Lopez, of Dublin (Hort. Trans. 1. 8.)
2. On the Character respecting the inuring Tender Plants to our Climate. (ib. 21.)
3. On the Revival of an obsolete Mode of managing Strawberries. (ib. 22.)
4. An Account of the Method of Cultivating the American Cranberry at Spring Grove. (ib. 25.)
5. On the Horticultural Management of the Sweet or Spanish Cherry. (ib. 27.)
6. On the Forcing-Houses of the Romans, with a list of Fruits produced by them now in our Gardens. (ib. 147.)
7. The Apple, a fruit in perfect perfection at Devonshire, in a Letter to him, by A. Hawkins. (ib. 175.)
8. An Account of the Discovery of a new Apple, called the Spring-Grove Codling. (ib. 197.)
9. On Ripening the second Crop of Figs that grow on the new Shoots of the Fig-tree. (ib. 211.)
10. Some Horticultural Observations, selected from French Authors. (ib. 220.)
11. Notice from a work of Monsieur Lecuir, on the Here- diary Diseases of Fruit-Trees. (ib. 247. Appendix.)
12. Notice to the first appearance of the Alpine Lian- gera, or the Apple-Tree Insects in this Country. (ib. vol. ii. 163.)
13. On the Advantages of turning the Branches of Fruit-Trees, to form a Canopy. (ib. Hort. Trans. 1. 8.)
1835. Dickson, Mr. James, F.L.S. V.P.H.S., of the respectable and long established firm of Messrs. Dickson and Anderson, seedsmen and herbalists in Commercial Street, Edinburgh, was in 1801, at Kirk House in Peeblesshire, in 1738, and acquired his first knowledge of gardening in the garden of the Earl of Traquair. He afterwards improved himself at Edinburgh, and was in 1750, the incumbrance of the late Mr. Jeffery; he was head gardener in several places till 1722, when he established the well known seed and herb shop in Covent-garden. Dickson's attention was always turned to botany when in a garden. He was one of his playmates enquire of another the name of a plant (Star of the Earth, Plantago Coronopus) which grew near them. Finding the boy able to answer the question, he felt at that time a kind of knowledge and superiority, and ever afterwards pursued his object with unremitting ardor. By directing his attention to a then neglected branch of gardening, he carried with him, says Sabine, "an imperishable reputation." He was one of the earliest members both of the Linnean and Horticultural Societies. See A Biographical Memoir, in Hort. Trans. v. App. 1.
1. On a Variety of the Brasica Napus, or Rape, which has been introduced into this country by Mr. Griffith. Hort. Trans. 3. 8. 2. Observations on, and an Account of, the Tubers of the Lathyrus tuberosus, with Instructions for the Cultivation of the Plant in a Greenhouse. Hort. Trans. iii. 259. 3. On the Cultivation of the Rampantia. (ib. i. 19. 1818.)
1865. Macdonald, Alexander, a fictitious name adopted by R. W. Dickson, M. D. formerly of Hendon, Middlesex, the author of "Practical Agriculture," and other works on farming.
1860. Anon. A lady, author of Conversations on Botany and some other works.
The Theatre of Plants. Lond. 8vo.
4. On the Management of Grapes in Vineries. (Hort. Trans. i. 186.)
1869. Knight, Joseph, F.H.S., nurseriesman in the King's Road, Chelsea; formerly gardener to Hibbert, Esq., at Clifton, whose collection of plants he now possesses.
2. On the Cultivation of Horse-Radish. (Hort. Trans. 1. 207. 1818.)
1870. Aiton, William Townsend, Esq., gardener to the king at Kew and Kensington. To the first situation he succeeded on the death of his father, William Townsend, Aiton, on the death of William Forsyth, Esq., in 1804.
2. An Epitome of the 20 edit. of Hortus Kewensis, for the Use of Practitioners in the Horticultural Line, to which is added, a Selection of Excellent Vegetables and Fruits cultivated in the Royal Garden at Kew. Lond. 1836. 8vo.
1870. Dean, R. and W., printners, Manchester.
1. An Account of the Paper Shelves used in Lancashire, Cheshire, &c. in the year 1835. To Which is Annexed, a Statement exhibiting at one view the number of Prizes won, by each season, for Shelves in all Parts of Lancashire, Manchester. 12mo. continued annually.
1810. The Calceolarian Horticultural Society. Founded in 1809, chiefly through the exertions of Dr. Andrew Duncan, Senior Professor of the In- stitutes of Science and Art, to the King of Denmark, at the royal gardens of Rosenhugl near Copenhagen.
1. (in the mode of forcing the vine in Denmark. Lond. Svo. 1831.
2. An account of the medicinal peaches in Den- mark and Holland. (Hort. Trans. v. 230.)
1811. Haynes, Thomas, nurseryman, at Oundle, Northampton.
2. Interesting Discoveries in Horticulture; being an easy, rational, and efficacious System of propagating all hardy annuals and perennials. Containing the history of the Original Tree and Shrub of general Description, Green-house Plants, Botany Bay and Cape Plants; Hardy Tropical Plants, affording shelter to the Cold-House Plants; and Plants for forcing, especially the Citrus, Cutting, chiefly in the warm months, with artificial heat. Lond. 1811. 12mo.
4. On gathering Seeds and Compos and preparing them for use, &c. Lond. 1813. 12mo.
Pomona Londinensia; containing representations of the best Fruits cultivated in Britain. 2 vols. Lond. 1813-40. 4to. To be completed in about 15 numbers.
STATISTICS OF GARDENING.  Part IV.

1811. Wade, Walter, M.D., Professor of Botany to the Dublin Institution.

1812. Cushing, —, a native of Ireland, late foreman of the hot-house department to Messrs. Lee and Kennedy, at the Hammersmith nursery.

1813. Hogg, Thomas, master of an academy at Paddington, Middlesex, and a very successful grower of fruit in that situation. 1.

1815. Ennemorton, Isaac, formerly a nurseryman and florist at Barnet, and an enthusiastic cultivator of the auricula.

1816. Salter, nurseryman, seedman, and florist, Wells Road Nursery, Bath.

1817. Brookshaw, George, a teacher of flower-painting. 1.

1818. Baldwin, Thomas, gardener to the Marquis of Hertford, at Ragley, in Warwickshire.

1820. Hayward, Mr. Joseph, gent., an amateur gardener, formerly a Yorkshire clothier, now residing at Plumstead in Kent.

1821. Macwilliam, Robert, a native of Aberdeen, and surveyor in London.

1822. Page, Dr. George, surgeon and Operation of the Dry Rot; to which are annexed, Suggestions for the Cultivation of Forest Trees. Lond. 1813.

1823. Page, Mr. William Bridgeman, C.M.H.S., nurseryman, at Southampton, and son-in-law of Kennedy, late of the Hammersmith nursery, who has lately published Mr. Page's Table of Fruit-trees, with the different descriptions of the same, in the style of those of Mr. Page's Sylva, and a short tract on the sexual system, from the Philosophical Transactions of London.

1824. This, when the errors with which it abounds in every page, are corrected in a new edition, will be the best Gardener's Cai- n of the genus, but they have been published; that they are much more correct and extensive as a botanical work, but this more instructive in what relates to culture. No gardener ought to be without both works.

1825. Sower, Robert, F.L.S., an excellent practical botanist.

1826. The Botanical Collector. Lond. 1809.

1827. W. Forster, the mimic at Stirling, inventor of a composition, which he sells for destroying all manner of insects.

1829. The Geographical Distribution of Plants through the Countries of Northumberland, Cumberland, and Durham. Lond.

1830. Phillips, Mr. Henry, formerly master of an academy at Bayswater.

1831. Forster, John, an English botanist, an Historical and Botanical Ac- count of Fruits known in Great Britain. 1832. 2 vols. 8vo.

1833. Silver Fierlers; or, the Shrubbery. 2 vols. 1832. 8vo.

1834. A Catalogue of All the Species and Varieties of Plants, with their botanical names, ac- cording to the latest decisions of the Linnaean System, and the Linnaean Society of London. 1833. 4to.

1835. The American Gardener; or, a Treatise on the Situation, Soil, and Culture of Fruits and Vegetables; together with the Management of Hot-hobs and Green-houses, and on the Propagation and Cultivation of the several Sorts of Vegetables, Herbs, Fruits, and Flowers. Lond. 1832. 12mo.

1836. Though the author shows great ignorance of botany and phy- siology, and his Pelargonium is for the most part constructed, and by curious and bold assertions, sometimes at variance with facts, to no certain end or book, from which we may say, that he was the author of the famous "Pelargonium" says that he has not a large garden, and a small but large gardener.

1837. The American Gardener; or, a Treatise on the Situation, Soil, and Culture of Fruits and Vegetables; together with the Management of Hot-hobs and Green-houses, and on the Propagation and Cultivation of the several Sorts of Vegetables, Herbs, Fruits, and Flowers. Lond. 1832. 12mo.

1838. The American Gardener; or, a Treatise on the Situation, Soil, and Culture of Fruits and Vegetables; together with the Management of Hot-hobs and Green-houses, and on the Propagation and Cultivation of the several Sorts of Vegetables, Herbs, Fruits, and Flowers. Lond. 1832. 12mo.

1839. The American Gardener; or, a Treatise on the Situation, Soil, and Culture of Fruits and Vegetables; together with the Management of Hot-hobs and Green-houses, and on the Propagation and Cultivation of the several Sorts of Vegetables, Herbs, Fruits, and Flowers. Lond. 1832. 12mo.

1840. Though the author shows great ignorance of botany and phy- siology, and his Pelargonium is for the most part constructed, and by curious and bold assertions, sometimes at variance with facts, to no certain end or book, from which we may say, that he was the author of the famous "Pelargonium" says that he has not a large garden, and a small but large gardener.

1841. Nell, Patrick, Esq. A.M. F.L.S., secretary to the Natural History Society of Edinburgh, and to the Caledonian Horticultural Society, author of a
BOOK I. FOREIGN LITERATURE OF GARDENING. 1115

6. Harrison, Mr. Charles, F.H.S., gardener to J. S. Wortley, Esq., Wortley Hall, near Sheffield, Yorkshire.

SECT. II. Of the Literature of Gardening in Foreign Countries.

1533. Champerie, Symphorien, a physician, a native of Lyons, who distinguished himself in the battle of Agnadela in 1569, and was made chevalier of the two gilt spurs; he wrote several works, and died in 1572.

Campus Elysius Gallis amemisti reperitus, in quo quidquid apud Indus, Arabes et Famos reperitur, apud Gallos monstrantur. (1533.)

1535. Etienne, Charles, a physician of Paris, who wrote several tracts on gardening and agriculture, and first united them in one work in 1536, De Primiis Ruris Cultura. Having married his daughter to Jean Leibault, also a physician, he produced, with his son-in-law, the Maison Rurale, 1570.

2. Semiarietum et Plantaria, Floriferiatarum, &c. Par. 1556. 2to.

1584. Brossard, Dassy or David, a Benedictine monk, having belonged to a family which still exists in the Maine, L'Art et Manière de semer Potirions, faire Pêpinières et Sau-

1553. Belon, Peter, a French physician, was born in the province of Maine about the year 1518. He travelled into Italy, Palestine, Greece, and Arabia, and published an account of those countries in 1555, 4to. He was assassinated at Paris in 1557.

1533. Cornus, George, or Gargote de Corne, according to some writers a native of Florence.

2. De la Manière de Planter, Arracher, Labourer, Semer et

Emonder les Arbres Sauvages, Bois Haut et Bois Taillis Paris, Svo.

1560. Dassy, P., that is, Père David, or David Brossard, De la Grand'Terre de Brabant. (See 1584.)

1563. Palissy, Bernard de, born at Agen in 1524, was a potter, according to some, and a China-ware manufacturer, according to others. He cultivated chemistry and arts, and went into Spain, where he wrote various pieces, which have been collected and published in several volumes. Those which relate to agriculture and rural economy, are entitled, De la manière de devenir riche. He died between 1602 and 1604.

1564. Recepte véritable par laquelle tous les hommes de la France pourront faire un jardin de fleurs, with the Dessein d'un Jardin délectable et utile. Rochelle. 4to. 1565.

1566. Mizaudes, —, born at Montluçon, in 1575; died at Paris in an advanced age. He studied mathematics and medicine with reputation; but his love of novelty, singularity, and astrology, made him lose in succession the little glory which he had acquired, and ruin both his health and his life. He published many works, chiefly in Latin; the first of which, on gardening, appeared in 1564; and all those which relate to the subject have been collected and published by Caillé, a physician, under the following title:

1578. Cousin, Jean, was born at Dijon, died at Paris in 1566; author of various works on medicine, and jointly with his father-in-law, Éti-
cune, of the Maison Raisone. (See Étiène, 1555.)

1581. — J. P. D. M., that is, Jacques Pou, Doctor of Medicine.

1582. Gersier, Claude.

Le maniér d’enter, planter, et semer, avec les ressources contre las moucheron, limos, et autres bêtes qui gatent les herbes et jardins. Tournes, 4to.

1568. Boyeau, Jacques, écuyer; sieur de la Barudu-
indre, intendant of the gardens of Louis XII.

2. Traité du Jardinage qui enseigne les Ouvrages qu’il faut faire pour avoir un Jardin dans sa perfection, et est manière de faire des pépinières, de gréssier, enter, &c. Dunois 1650.

1651. Molet, André, a relation and contemporary of Claude Mollet, who was gardener to Henry IV., and Louis XIII. of France, as the other is said to have been to James I. of England.

1. Le Jardin de l’Alsaz, contenant plusieurs Desins de Jar-
116

STATISTICS OF GARDENING.

PART IV.

2. L'Art de cultiver toutes sortes de Fleurs; avec Instructions pour les cultiver et greffer les Arbes Fruitiers. Paris. 1762.

4. D.C. D. W. Le Jardinier, ou le moyen de cultiver les Arbes et les Herbes Potagères, avec la Manière de cultiver les Fruits, dîend ou laissés à terre. This work has come through a great many editions in France, and was translated by Evelyn in 1698, under the title of The French Gardener.

8. Quintine, Jean de la, born in 1625, at Chalais, near Angoulême, died in 1700. He was destined for the bar, but a passion for gardening terminated this pursuit. He became tutor to a young gentleman, M. Tambonneau, and made the tour of Italy with him, where his passion for horticulture was increased. At his return, he became the master of his pupil transmitted his gardens to his direction. Here he acquired experience and reputation. The great Conde employed him for pleasure in conversing with his garden. He was, in 1711, England invited him to look after his gardens, with a considerable pension. Louis XIV, created him for the office of director of the royal fruit and kitchen gardens. It is uncertain which work, however, was composed by him appearing in the life of the first of those enumerated below.

2. Instructions sur les Jardins Fruitiers et Potagers, avec un Traité des Orangers, et des Réflexions sur l'Agriculture. 4to. 1762. This work was translated into English and French, and were translated into English by Evelyn, and published in London.

FRENCH WORKS ON GARDENING.

2. Sur le Cultivage des Arbres, étrangers pour l'emploi de plusieurs Terrains de différente nature abandonnés comme steriles. (Mem. de la Soc. d'Agricult. de Paris, 1762.)

4. Mémories sur les nouvelles Sortes de Greffes. (Ibid. tom. 2. & 3.)

9. Buffon, George Louis le Clerc, Count de, was the son of a councillor of the parliament of Dijon, and was born in that town on the 26th of Dec. 1707. He studied at Dijon, and was intended for the law, but his inclination lay to the sciences, particularly astronomy and geometry, and it is said he was never absent at the public lectures of D'Anville's. At the age of twenty he made the tour of Italy, after which he visited England. On his return he divided his time between Paris and Dijon, and in 1735 published a translation of H. Martens' Observations, which was followed by one of Newton's Experiments.

10. In 1730 he was appointed superintendent of a royal garden and cabinets, which by his care were considerably enriched. He was a member of the French Academy, treasurer of that of Sciences, and in 1716 he was created a count. His private character was that of a liberal man, and he was extremely vain of his person and talents.

"The works of eminent geniuses," he would say, "are few; they are those of Newton, Bacon, Leibnitz, Montesquieu, and Rousseau." These were engraved on a stone in 1788. His only son was guillotined in 1793.

11. Mémories sur la Conservation et le Rétablissement des Forêts. (Ibid. tom. 1.)

12. Mémories sur la Culture des Fruits. (Ibid. 1749.)

14. Buzin, Gilles-Angust, a physician of Strasbourg; author of some tracts on insects, trees, &c; died in 1754.

17. Coupland, John, a native of Lyon, began to write on agriculture in 1745, and after a very hard life of agitation, he retired to a country-house near Paris, where he gave himself up to gardening.

18. Art Hospital in Paris in 1784. One of the most indefatigable compilers of the 18th century.

3. Francheville, Joseph Dufresne de, of the academy of Berlin, born at Dourlens in Picardy
in 1744; better known by the first edition of Voltaire's *Siecle de Louis XIV*, which appeared under his name, than by any of his other works.

*Catalogue nouveau de bons Fruits*. 12mo.

1757. *Bertrand, Francis*, a citizen of Paris, en-thusiastic of the natural style, being not being able to retire to it, he amused himself by collecting passages from the poets on the pleasures of a country life.

*Pour délicat. Collecte ex melioris nostre Latins Gallicisque Poetis. Par. 12mo.*

1758. *Mony, N.* of Lyons, born 1725. An ancient architect, who introduced the modern style of gardening in France. He assisted Girardin in laying out Érmenonville, and afterwards was employed on the extensive concerns of the park of Morevillé.

An improved edition, enriched with a list of trees, their heights and colors, by C. Meriol, in 1803.

1759. *Bidet, M.* of, the agricultural academy of Tuscany, and officer of the royal household; a native of Champagne.

1760. *Buchoz, Pierre Joseph*, a physician and meteorologist; born at Montbéliard, died in great distress at Paris in 1807. He wrote above three hundred volumes relative to medicine, agriculture, the veterinary art, and natural history.

5. *A. Buchozian*: was named after him by L. Herilit.

He printed numerous other dissertations of this description separately, which are all collected in the following works.

7. *Observations sur Quatre Génres d'Arbustes*; l'Azaïla, le Camélin, le Pommier, et le Mandragone; méritent d'être cultivés dans les Jardins. 8vo. 1782.

9. *Buchoz was at this time botanical demonstrator to the Royal College of Physicians, at Nancy.*

1759. *Duchesne, Ant. Nicolas*, professor of natural history, in the central school of Versailles, author of the:

1759. *Thierrat, M.* a lawyer, and an officer in the woods and waters; author of various tracts on agriculture.

11. *Observations sur la Culture des Arbres à haute Tige, par-ticulièrement des Pommes.*

Le Jardinier d'Artois, ou Éléments de la Culture des Jardins, &c. 8vo. 1789.

1759. *Maupia, M.*, valet-de-chambre to the queen; author of a number of works on rural subjects.

16. *Lettre de l'Auteur de la nouvelle Méthode de cultiver la Vigne sert de réponse à une réponse*.

An new edition, with additions, by Buchoz in 1799.

1759. *Chambray, Louis, Marquis de*, born in 1708, occupied himself much in cultivating the apple, and in making cider.

Art de cultiver les Pommes, les Poiriers, et de faire les Cidres, selon l'usage de Normandie. Paris 12mo.

1759. *Delille, Jacques*, an eminent French poet, member of the French Academy, born at Clermont, in 1758; died at Paris in 1811.

18. *There is an English translation by Mrs. Monticelli, in 1797, of the last of his works, couched in an Epître a deux Enfans Voy-ageurs. Paris 18mo. 1817.*

1763. *Dupuy, Jean*, on the Culture of the Vigne.

1765. *Saint-Péral, Guertrude de*, born in Beauce, author of some tracts on political economy and agri-cultural science.

1773. *Traité de la Culture de différentes Fleurs, des Narcisses, Girofléres, Tubéreuses, Anémones, Jacinthes, Jonquilles, Iris, Muscaris, &c.*

1767. *Sauvage, Jean-Roger*, a deacon, the son of a sculptor, who occupied himself much in gardening, and wrote several works, not elegant as to style, but entirely from his own experience. He died in 1767.

2. *Theorie et Pratique du Jardinage, as compiled from the author's papers, and published after his death, by Desralier d'Argenville, who collected and published them under the title of "Manuel du Jardinier, ou Journal de son Travail distribué par Mois." Paris. 12mo. 1776.*

4. *School, de l'Abbey, died young at Paris in 1775, and was known for his political economy, which obtained the prize of the academy of St. Petersbourg in 1769.*

1769. *Quéyroy, M.* a deacon, and for the école en treillis, by the Sieurs de Larivière and Dumoulin. Paris. 12mo.

1769. *Toutain-de-Limcy, Charles François*, an officer in a regiment of Champagne, under the old regime, member of several agricultural societies.

1770. *Anon.* The Jardinier prévoyant, Almanach suivi des Considerations sur la Culture des Pommiers.*

This work has been improved, and continued to the present time, under the title of the Annuaire du Jardiner, etc.

1771. *Hérisant, Louis Antoine Prosper*, born in Paris in 1745. His father was a celebrated printer, and the son was educated as a physician, but died in 1758, at the age of twenty-five.

Jardin des Curieux, or Catalogue raisonnable des plantes les plus belles et les plus rares, et indigènes des diverses parties de la France, Latins, et leur culture et les vertus particulières de chaque espèce; le tout précédé de quelques notes sur les plantes générales. Paris 8vo.

This work is the description "raisonnée" of a fine garden which Mr. Cochin, an ancient magistrate of Paris, had formed at Chartillon near Bagneux, within two miles of Paris. Héris- sant died before his work was completed, and it was finished by his son.

1771. *Latapey, M.* the translator of Wheatley's *Observations on Modern Gardening*; to which he added, a Discourse on the Origin of the Art, notes.
to the text, and a description of Stow, where he is said to have resided some time with Lord Temple.

1790. Hervé, M. Villé, director of the Royal Garden of the Luxembourg. Mr. Hervé's father was gardener to the Grand Duke of Luxemburg. His fruit trees had been collected and propagated for upwards of half a century before the revolution. In the early part of this revolution, the elder Hervé, foreseeing the establishment of the First Republic, put in writing, for and obtained permission from the existing government to establish a national garden on the site of the garden of the Luxembourg, and the Luxemburg was made the receptacle of this collection.

A new edition, with a supplement, on the Greifs, in 1809. Svo.

Catalogue Méthodique et Classique, de tous les arbres, arbustes, plantes médicinales et de toutes les graminées de l'ordre de Poéme, établi pour le département du Luxembourg. Paris. 1809. 8vo.

Fruit-trees, the abbé de la Bois, was born in 1754, and killed there on the 29th September, 1753, during the siege of that city, by a bomb-shell, which buried his scattered remains in the ruins of the apartment which he occupied. He began his career as an author, by writing in the Journal de Physique et d'Histoire Naturelle, of which Gauthier Dugoy was editor. He next occupied himself with his Vues et Description d'un Rural Dictionary, which is the work by which he is chiefly known. He cultivated a farm near Beziers, which Arthur Young went to see when on his tour in France in 1787; but the affair was not a fortunate one for the Bishop of Beziers, who kept a mistress somewhere near, and, for his more commodiously visiting her, got a road made across the farm at the expense of the proprietors. They determined a quarantine to be between the abbé and the bishop, which ended in the former being obliged to quit his farm. The abbé, like all other men who depart from common practices, was supported by several persons about him. The abbé of near, a faithful and wild cultivator, and because he paved his stables and cow-houses, was reported by his neighbors that he paved his vineyard. He wrote a great many works, chiefly on agriculture.

2. Cours complet d'Agriculture théorique, pratique, économie, &c. 15 vols. 4to.

3. Traité de l'Art de cultiver les Jardins, les vignes et les arbres fruitiers, &c. 12mo.

4. Sur la Réception des plantes qui viennent d'étranger, &c. 2 vols. 8vo.

5. Considérations sur l'art de cultiver les jardins potagers, les arbres fruitiers de toutes espèces; tous les oignons, et plantes à fleurs; les arbres et arbustes d'ornement, le chêne de couleurs, &c. Paris. 12mo. 1798. Brielé, ---, an officer employed in the management of the national woods and waters at Orleans. 

16. Dalmar, Basze N., a native of Germany, purchased the estate of Villiégeries, near Paris, and great part of Bougival, as both its use and beauty. De la Utilité et de la Culture de l'Acacia-Robinier: dédié aux yeux du prince de Condé. Paris. 1801.

20. Lemoine Léonard, founder of an academy of theoretical and practical gardening, held in Paris, Rue-d'Enfer.

1811. Robin, C., — cultivator.
1802. Caillet, Étienne, member of several literary and agricultural societies, and a scientific experimenter in the latter art. Paris. 8vo.
1805. Bastien, Jean François, a bookseller of Paris, who put himself out as the author of several books on agriculture which he procured to be printed. Paris. 12mo.
1810. Micheau, F., — a celebrated naturalist, who has published, in Paris, a Memoire sur le tableau raillier de ces des Fosses, compared with those which he has done for France. Paris. Svo. 1810.
1807. Cadet-de-Faux, Antoine-Alexis, born in 1763, a patriot, incessantly engaged in the interests of agriculture, and by his example, foundation of several useful establishments, and among others, public nurseries in the departments. He translated the chemistry of Spelman. De la culture et du Gouvernement des arbres à fruits, mutilés et dégradés par la succession annuelle de la pluie et du soleil. Paris. Svo. 1807.
1808. Deuxiéme-Richardot, cultivator (or yeoman) at Langres, who has planted extensively, and if not the inventor, was the first to publish in France the mode of cutting and stripping trees, and removing a part of the ground’s surface, and cutting over close by the roots, or what the French term cutting entre deux fertes. Le la Coupe des Bois entre deux Terres. Paris. 8vo.
1811. Jardin, Ch. Ph. Comte de, an active patriot and philanthropist, author of various works on agriculture and general economy; chiefly known by his treatises on wool, Merino sheep, and education. Notice du Jardin du souvenir du Nouveau de la Quintaine. 8vo. 1811.
1811. — Lointier de Longchamps, M.D., one of the compilers of Le bon Jardinier. (See Anon. 1770, and Delaunay, 1811.) Nouveaux Principes du Traité des Arbres, et Arbustes qu’on culture en France en pleine terre. Paris. fol. 7 livraisons, in 1811.
1811. — NOSETTE, Louis Claude, botanist, and nurseryman at Paris, one of the compilers of Le bon Jardinier. (Anon. 1770, and Delaunay, 1811.)
1812. — Le Jardin Fruiteur. 12 livraisons. 4to. 1813.
1814. — Notice des Jardins de l’Ambassadeur du Nouveau de la Quintaine. 8vo.
1815. — KIRK, James Charles, a German architect and designer, author of an esteemed work on carpentry.
1816. Plan de plus beaux Jardins Pittoreseques de France, d’Angleterre, et d’Allemagne, et des edifices, monuments, fabriques, etc. qui concourent à leur embellissement, dans tous les genres d’architecture, tels que Chinois, Egyptien, Anglais, Arabe, Moresque, etc. Paris, imper. fol.
1811. Delaunay, Mordant, one of the librarians of the Jardin des Plantes, principal editor of the following works. (See anon. 1811.)

2. Figures pour l'Amanach du bon Jardiniere. 12mo. 1811.

3. Guillemin, George, sub-prefect of Savonna, near Genoa.

This splendid work contains, in most cases, plans of the gardens, and details of the villas.

1815. Montpellier, J. —, cultivator in the department of the Aude.

Des Cultures des Arbres Fruits. Castelnaudary. 8vo.

1816. Malo, Charles.

1817. Mordard, Jean, proprietary cultivator at Montpellier, near Paris, a village famous for its peaches. Mordard was successor to Popon, who was distinguished as the first cultivator of peach-trees at Montpellier, or, indeed, in France, from 1720 to 1770.

Pensees sur l'education, la culture, la taille, et l'embourrement des arbres fruitiers, and principally of the peach, d'apres la Method of Fequin and autres Cultivateurs de Montpellier, ouvrage qui a obtenu deux Medailles d'Or de la Societe Royale d'Agriculture du departement de la Sedaine. Paris. 8vo. 1819.

1816. De Coutours.

Tables Synoptiques des caracteres differents de la Vigne. Toulouse. 8vo.

These tables are for the most part taken from Clements's work. (See Clerc's Histoire des Vins de France. 1816.)

1817. Du Petit Thouars, the Chevalier Aubert Aubert; director of the government garden of the minister of the interior.

Le Moniteur de la Societe Centrale des Freres et de la Culture des Arbres Fruitiers, institue dans les diverses particulieres de la Societe d'Agriculture of France. Paris. 8vo, 6 plates.

Memoires de la Societe d'agriculture de la province de Limousin, &c. Mémoires du Vigneron du Departement de la Morelle. 12mo.

1819. Thouin, Jean, C. M. H. S., brother to the professor, and to Gabriel Thouin; foreman of the Jardin des Plantes, Paris.

Memoire sur l'Emploi de Machefer dans le Jardinage, &c. 1819.

1819. Lambray, X. —, nurseryman at Mandres, in the canton of Bussy-Saint-Leger, in the department of Seine et Oise.

This author practices ringing when the vine is in flower, which he finds has the effects to which he alludes in his title.

SUBSECT. 2. Works on Gardening published in Germany, including Denmark and Switzerland, exclusive of Translations.

1817. Redoute, J. —, painter of flowers to the Classe de Physique of the Institute and of the Medical Society.

1818. Frais, Antoine de.

1818. Risso, J., of Nice, and A. Pauteau, of Versailles.

1819. Boss, Louis Auguste Guillaume, F.L.S. H.S., inspector of the government garden at the Luxembourg. In his Mims, he has published various articles in the Nouveau Cours d'Agriculture, and in other works.

Exposition du Plan de Travail adopte pour etudier et classer les diverses Varietes des Vitis cultivées dans les Peupliers du Luxembourg. (Journal de Physique, tom. 65.)

1819. Thouin, Gabriel, cultivator and architect of gardens, brother to Professor Thouin, of the Jardin des Plantes.

1819. Thory, Claude Antoine, clerk in the office of the mayor of Paris, member of several learned societies.

1819. Flarti, —, proprietor and creator of Jardins Pittoresques at the park of Bruchau.

Le Guide des Plantes des Jardins Ruits, qui s'occupent de la Composition de leurs Jardins et de l'Embellissement de leurs demeures. Paris. 12mo.

1820. Beauvill, —, author of a treatise on bees.

1820. Chevill, Markis de.

Histoire de la Rose chez les peuples de l'antiquité et chez les modernes; description des especes cultivees; culture des Rois; et leurs diverses propresities alimentaires et domestiques. Toulouse. 1 vol. 8vo.

1820. Fibert, J. —, painter.

Catalogue de Rouen. Rouen. 8vo.

1820. Lehret, N. —, druggists and proprietors of flowers.

Memoires sur la Trappe Natana, ou la Chateauneuf. Rouen. 8vo.

1820. De Candolle, A. P., professor of botany in the academy of Geneva, author of Regni Vegetabilis Systema Naturale, now publishing; of various other botanical works, and of several articles connected with culture, in Nouveau Cours, &c.

1. Memoir on the different species of the genus brassica, and of the family of the Cruciferous Plants, &c. Rouen. 1820.

Duke of Cleve; was born in 1508, died in 1576. He wrote various theological works; besides his Hei Rubea, 1644, was discovered in 1576, and his Legum rusticarum, et operarum per singulas Moscas digeata, in 1593. The former was translated by Dr. G. Gooch, of Lincolnshire, with the following title:

Four Books of Husbandry, containing the whole art and trade of husbandry...with...Frankfort. At London, 1670. 4to. Leaves 191, besides the Dedication, Epistle and Table at the beginning; and Oide English rules in verse, for purchasing Land, etc.

His authors extended from the Bible and Doctors of the Church, to Pliny, Gessius, and Celsus, etc. to the moderns as Laurellus, Fuchsius, Matthioli, Candanus, and Treps. He subjoins a list of his friends and others to whom he is indebted; and, among the rest, Dr. N. N. N. of Silesia, 1639. Deering, ham, M. &c. his EnsHcee Hortorum, Grundliche Horticultura, Dendrograph^a, De Unterricht Catalog! Programma 1696. 1662. 1663. 1704. 1700. 1713.

Devey, Johann, Daniel, author of a naturalist's calendar, and some other works.

1750. Krause, L. P. h., born in Berlin, where he was a nurseryman.

Klaper, siehe antigetär Gärten. Leipsic. 8vo.

1751. Ungehauser, Johann Andrew. Dissertatio deculatura plantarum. Leipsic. 4to.

1753. Lehmann, John Christian, an amateur, who lives in Leipsic.

Volkommener Blumen-garten in Winter. Leipsic. 4to. p. 71, 1 plate.

1761. Gesner, John, a canon of Zurich, and professor of mathematics and natural philosophy in that university, was born in 1709. He studied at Leyden and Basle, where he contracted an intimacy with Haller; and many epistles have been exchanged between them. He died in 1759. Gesner published two dissertations on plants, in 1741, in which he announced the new system of Linneus, of whom he says, that he was a man destined to give full natural history. Besides these, he was the author of eleven dissertations, published under the title of Phytographia Sacra. He also wrote on extraneous fossils; and compiled an index to Wilmann's Phytographia. But he was grossly imposed on, as well by Haller, by the present of a meadow crowfoot, on the branches of which the species had been newly fastened as escape detection fall after Gesner's death. Of this he published a description, in a learned discourse on vegetable monsters, entitled, De Rarissima Plantarum. The author of this work, Sir Joseph Banks, who procured the specimen, and separated the parts by the application of steam.

De Rarissima Plantarum, et Plantarum generibus. Zurich. 4to.

2. Theses Physicæ Miscellanea speciétum de Thermoscopio Botanico. Zurich. 1755. 4to.

1765. Reichard, Ch., a celebrated writer of Guides, and other compilations, who lived at Erfurt, and died some years before.

Land- und Gartenkraftsch. Erfurth. 8vo.

1776. A new edition in 1792, by F. J. Volckersick. 1776. De Historia plantarum et anatomie plantarum et animae, altissimique artium et scientiarum ad illum pertinentiam realis systematice. Leipsic. 4to. 1788. p. 287. This is considered a very valuable work.

1776. Schlegel, Jus. Ob. The wondrous vegetable creation on which the earth is symbolically and figuratively described, and the manner in which vegetation begins. Published, 1745. 1778. Programme de planter sub-diverso cole nascentium cultura. Leipsic. 4to.

1783. Goethe, John Gottlieb, a naturalist, who was born at Leipsic in 1744. He took his doctor's degree in physic at Frankfort on the Oder; where he was appointed professor of botany, physiology, and medicine. He was also a member of the Academy of Sciences at Berlin, and died in 1786.

SUBJECT. 4. Works on Gardening originated and published in Holland, exclusive of Translations.

7695. The Dutch excel more in the practice than in the literature of gardening. The works of La Court, and Van Osten, the former little known, are among the best that have been produced. There are none of recent date of any considerable consequence. The Journal of a Horticultural Tour in Holland, &c. by a deputation of the Caledonian Horticultural Society, gives the best idea of the state of gardening in that part of the Continent in 1817.

1593. Curtius, Benedictus. Hortorum liber XXX., in quibus contenuntur hortorum historia, parum ex probatissimis quisquebus auctorum libris, parliam ex auctorum propria, quamvis eorum etiam partes. Leyden. 1693. 8vo.

1613. Meursius, Jan, died at Leyden in 1613, in the flower of his age. De arborum fructibus et herbarum proprietate usus et qualitates, lib. III. Leyden. 1620.

1631. Clagett, Oudger Angierus, author of some works on the plant kingdom and insects. Memoire de la vreende bloem-bollen, wortelen, vruchten, planten, structuren, xaden ende vruchten, hoe men die sal wel gemachtighd bevaren en eere over aanden, that is, Memoire on the mode of preserving and sending over in good condition foreign bulbs, roots, herbs, plants, shrubs, seeds, and fruits. Amsterdam. 1660.

1683. Vander, Groen, I.----, gardener to the Princes of Orange.
Le Jardinier Hollandais, avec environ deux centes medailles de plantes des plus beaux autres; laburnins, parillons, ouragres, treillis et mailles de betes, et de quadrans et horloges solaires. Amsterdam. 1692. 12mo.

1689. Van Steurberck Francis. Citrulture, of regenerating the sytheniche boomen. (Of the cultivation of the damaged trees.) Amsterdam. 1689. 8vo. (The Dutch Gardeners, &c. Lond. 1710. 8vo.)

1721. De Flier, John, supposed to be a French Gardening Writer.
Le Jardin de Hollande planté et garni de fleurs, de fruits, et d'arbres de l'Europe. Le tout après une longue experience, mais aujour pour l'intérêt public. Amsterdam. 1700.

1757. Anon; the author Mr. La Court, a Dutch merchant, who had a country-house and fine garden at Driebruck, (triangle), near Leyden, where he was the first to introduce and cultivate, with success, the garden plants and the tuberous. He died between 1737 and 1740.

Ammendationer over het aenleggen van landhuisjes, luthoven, plantagijns, &c. &c. (Remarks on the laying out of country houses, pleasure-grounds, plantations, &c. &c.) Leyden. 4to. p. 415, with 15 plates.

These plates contain plans of pits for growing the pine and the vine; a general plan of Driebruck; and figures of the pine- cones, tubers, and some varieties of oranges and lemons. The book is very scarce; only a few having been printed. The only copy we have seen is in the Brunswick library.

1752. Voorheem, George. Commercial Florist at Haerlem, of the firm of Voorheem and Van Zompel. Traite sur la Jardinier, 2 parts, 8vo.

1757. Campan, or Campen, and fils, florists, at Haerlem.
Traite des fleurs a olignons. Sw. with plates; translated with this title.

The Dutch Florist; or, true method of managing all sorts of Flowers and bulbous roots. 4to.

1771. Koning, or Van Horssen, a gardener at Leeuwarden, in Friesland, died about the end of the 18th century.

1. Pomologie, or description the beautiful sorts of pomes and of poires that l'en amie and cultive the plus, soit aux Pays-bas, soit et Amsterdamer, soit et Angliaste. Amsterdam. 1640.

2. Fructologia, or description the arbre fruits, ainsi that des fruits que l'on rmente et quon cultive communément dans les jardins. Amsterdam, folio.

An anonymous work, with nearly the same title, appeared in 1774.

1784. Burton, Francis Xavier, a physician in Lorraine, author of some works on mineralogy.

Membre sur l'histoire des plantes indigene que l'on pourrait substituer dans les Pays-bas, aux vegetaux exotiques qui y sont representes, by woollen cloth, in twelve volumes, fols. The two first volumes however, were so unforte.

SUBJECT. 5. Works on Gardening, published in Sweden, Norway, and Iceland exclusive of Translations.

7696. Scandinavian books on gardening are few, and chiefly by Linnaeus or his pupils. A knowledge of the present state of culture in Sweden is best obtained by reference to the transactions of the Stockholm and Upsal Academies.

1664. Sparr, a physician, was the son of the Bishop of Vasteras, and born in 1661. While a student at Upsal, he discovered the lymphatics in the liver, and other parts of the body; though his claim of priority was contested by Bartholin. He also cultivated botany, and founded a garden for the university of Upsal, where he held the chair of medicine till his death in 1702, having resigned the professorships of botany and anatomy, some years before, to his son, of the same name.

This was to a vast work, in which all the known plants in the world were to be represented by wooden cuts, in twelve volumes, fols. The two first volumes however, were so unforightly.
1180

STATISTICS AND FINLAND.

Fragrance, foundation where the Sweden which interred was. In the purpose of exploring that country; where he remained two or three years, and then returned to Abo. He afterwards made an extensive tour in Russia, with the same object, and died in Sweden in 1779. His Travels in America were translated into English by Forster, in 1774.

1754. Kalm, Peter, a naturalist, was born in Finland, in 1715. He became professor of botany at Abo, in 1743. Forster, in his Travels in Russia, says that he undertook the care of many valuable plants, and trees; the growth of which was of such a nature as was suitable for Finland. This remarkable work has been translated into several European languages.

1752. Wallerio, Johanne Gotschall.

Præsides, Dissertatio de artificiis fecundationum, immersa seminum e quoque solis materia. Stockholm, 1744. 8vo., p. 207.

SUBJECT 6. Works on Gardening, published in Poland and Russia.

17697. Of original Polish or Russian books on gardening there are very few; but a number of translations were made in Poland during the early part of the 18th century. There are agricultural transactions published occasionally by a society at Warsaw, which, with the transactions of the Economical Society of St. Petersburg, may be considered as the best books for obtaining some idea of the state of culture in these countries.

1788. Samboursky, a Russian poet, author of a number of works chiefly in verse, and of a poem on gardens, which has been translated into French, with the title Le Jardins de Samboursky. 8vo.

1795. George, a physician, and member of several learned societies. Description de la Ville de St. Petersbourg et de ses Environs. Petersburg. 8vo.

18—. Lomonosow, a Russian poet and miscellaneous writer, author of a poem on glass, and the advantages resulting from its use in a northern climate. The subject of hot-houses forms a considerable part of the poem.

1805. Czartorysky, Princess Isabella, a lady of one of the most ancient families in Poland in the royal line. She spent a considerable time in England, where she acquired a taste for the modern art of laying out grounds, introduced it on her estate at Lublin, and wrote the following work on the subject.

Msyl Kreze o Spomnialna Ogrody, &c. (Thoughts on the manner of Planting Gardens.) Warsaw. 4to. plates.

SUBJECT 7. Works on Gardening, published in Portugal and Spain.

17698. The transactions of the royal agricultural society at Madrid, are almost the only recorded source of obtaining any knowledge of the state of culture in Spain.

1787. Cavanilles, Antonio Joseph, an eminent botanist, author of various works, and among others, of Figures and Descriptions of the Plants of Spain. De la Juncia sylvanada, o chufas de Valencia. (Annuelles de Ciencias Naturales, tom. iii. 251)

SUBJECT 8. Works on Gardening, published in North America.

17699. A number of American essays are connected with gardening will be found in the agricultural transactions of the Philadelphia and New York societies, in the transactions of the Society of Arts of New York, and in Dr. Dean's New England Farmer's Dictionary. Cobbett's American Gardener may be considered as affording a tolerable picture of the state of gardening in the United States, where it appears the long and severe winters are material drawbacks to every branch of the art.

1790. Peterskis, Joshua. A Treatise on Planting, from the origin of semen to ebollition, 3d edit. Basaterre, St. Christopher's. 4to.

CHAP. V.

Of the Professional, and Public Laws relative to Gardeners and Gardening.

7700. By professional police, we mean those associations which gardeners have formed, at different times, for mutual benefit or instruction, or the improvement of their art; by public laws, those of the legislature.

7701. A fraternity of gardeners, we have already remarked, has long existed in Germany as regularly organised as that of masonry. A fraternity also exists in France, but less extensive and systematic. Their principal lodge is at Versailles; the confrères de St. Fiacre, being there, as Nell observes, to France, what "Adam's lodge of Aberdeen is to Scotland." There are also a few similar fraternities in this country, who hold meetings, and have secret signs and other rites nearly similar to those of masonry; but these societies have no systematic connection like those of Germany. From masonry they have undoubtedly taken their origin; but how, when, and where, and for what object, in the first instance, though we have corresponded with competent persons in all parts of the kingdom, we have been unable to ascertain.
7702. The oldest gardeners' lodges seem to be those in Aberdeen-shire, and Adam's lodge, held in the city of Aberdeen, is considered the oldest in Britain: there is another of nearly equal antiquity, called Solomon's lodge, held in Banf. These lodges profess to be for the mutual instruction of the members in their art; for the assistance of brethren in distress; and for the benefit of travelling members. The first object is attained both by secret instructions, and also by competitive exhibitions of garden productions, as flowers and fruits; the second, by annual subscriptions, from which a fund is formed, managed by a committee of the society; and the third, by signs and pass-words, as in masonry. They have a general meeting, formal procession with symbols and flowers, and afterwards a feast, once a-year. There were formerly a number of gardeners' lodges in Scotland, and there are still a few besides those of Aberdeen and Banf, but chiefly confined to the counties of Aberdeen, Forfar, and part of those adjoining.

7703. The principal Scotch gardeners' lodge, though it has no connection or control over the others like the metropolitan masons' lodge, is the Caledonian lodge of Edinburgh, founded about the end of the last century: its object is the same as that of the Aberdeen lodge; but it has no shows of flowers, or other garden productions. Their meetings are respectable, their processions pompous, and their funds considerable.

7704. There are very few gardeners' lodges in England; the only one of which we have been able to obtain any distinct account is "Adam's Lodge, of London," founded June 4, 1781, of which the rules and orders have been published. This lodge is described in the Rules, &c. as a "Fraternity or community for improving the art of Gardening; to establish a fund for the mutual support and relief of each other in the time of sickness, lameness, or distress; and also to ascertain the characters and abilities of such gardeners who shall belong to, or may be recommended by this society, to obviate the difficulty so commonly complained of by the nobility, gentry, and others, of obtaining skilful and experienced persons to undertake the employment." At present it consists of about one hundred and fifty members, and is on the decline. The allowance to the sick or disabled has been gradually diminished from insufficiency of funds; and from having been originally fixed by a random guess, instead of estimations of the value of lives, &c. as ought to be done in all benefit societies.

7705. Gardeners' charter. About the middle of the last century, Lee, Gordon, Rus- sel, and Malcolm, all Scotch gardeners, commenced their nurseries at Hammersmith, Mile-end, Lewisham, and Kennington. Their success excited the jealousy of the established commercial gardeners, who, between 1760 and 1770, held several meetings, and entered into resolutions not to employ young men from the north. These resolutions were not long adhered to; but a tract, entitled Adam armed (see p. 1106. A.D. 1760.), published by this association at the time, shows the extent of what they intended. From this tract it appears, that James I. had granted a charter to certain persons inhabiting within London, and six miles of it, who were capable to educate and instruct young men in the art of gardening. This charter was granted in the third year of this king's reign, and renewed in the fourteenth; but in the tract alluded to it is stated never to have been put in force, and not to be sufficiently extensive; and therefore it is proposed, that a charter be granted to extend over the whole kingdom, to prevent mere laborers and other unqualified persons from assuming the profession of gardeners, and thereby doing "great injury to the nobility's and gentry's gardens and plantations," as well as to proprietors who let ground to such as "undertake to furnish the market with eatables." Only a certain number of gardeners were to be licensed to take apprentices, and of these the number was to be limited, &c. This attempt at monopoly of skill does not appear to have met with serious attention, and all that resulted from the association, as far as we have been able to learn (from a gardener, Duncan, upwards of 90 years of age), was the partial exclusion, for a year or two, of young Scotchmen from a few of the nurseries and gentlemen's gardens near town, which were managed by Englishmen.

7706. The origin of florists' societies we have not been able to discover. It is more than probable that meetings for the display of fine flowers and the estimation of their merits, were first held at Norwich, where, as Sir J. E. Smith informs us ((Supp. Encyc. Brit. art. Bot. 336.), a love of flowers, and a great degree of skill in their culture, had been introduced into that city with its worsted manufactures, about the middle of the sixteenth century. At all events, there were florists' feasts held there so early as 1637; a play called Rhodon and Iris, being extant, which was acted before the company in that year. (Linn. Trans. vol. ii. p. 226.) The next florists' meetings, it is probable, sprang up about London; and Nathaniel Rench, of Fulham, is said (Faulconer's Historical Account of Fulham) to have been the first who established them, probably about the end of the seventeenth century. According to Davey, florist, King's Road, whose father was also an eminent florist, and lived to upwards of ninety years of age, the florists' feasts and meetings were at their greatest height about London, between 1740 and 1770. They were then attended by many noblemen and gentlemen, as the horticultural societies are at present. They declined towards the end of the last century, but have since revived, and are
at present rather on the increase. The florists' meetings, and those of gooseberry-growers in Lancashire and the adjoining counties, are very numerous, and rather on the increase. When they were first adopted in that part of England is not exactly known. From the best accounts we have been able to collect, they were in vogue there in 1760, and are re-collected so far back as 1740. Some florists' societies existed in Edinburgh during the latter end of the last century; and on one of these the Caledonian Horticultural Society was founded. The principal florists' societies in Scotland are at Paisley.

7707. The principal modern societies for the encouragement of gardening are, the London and Caledonian Horticultural Societies, whose transactions are so frequently referred to in this work.

7708. There are few public laws specially formed for the two first branches of gardening, horticulture and floriculture; the general laws being quite sufficient for their protection. Robbing of orchards or gardens, of fruit growing therein, is punishable criminally by whipping, small fines, imprisonment, and satisfaction to the parties wronged, according to the nature of the offence. (43 Eliz. c. 7.)

7709. There are a number of acts relative to arboriculture, and especially against the cutting down of young trees. (See Tomlins's Law Dict. vol. ii. art. Timber.)

BOOK II.

OF THE FUTURE PROGRESS OF GARDENING IN BRITAIN.

7710. The improvement of gardening, like that of every art or commodity, necessarily depends on demand and production. These causes operate reciprocally on each other: a nicety of taste in the purchase of vegetables and fruits exposed in public markets, will occasion articles of better quality being brought there; and articles of a superior quality, by improving and rendering more fastidious the taste of the purchaser, will ensure the continuance of their production. In like manner, if those who have private gardens were a little more difficult to please in selecting a gardener, and in the quality of the produce sent to table, the consequence would be, an improvement in that produce, and more scientific gardeners. More scientific gardeners would surprise and delight, by their superior fruits and flowers, and the greater order, beauty, and high keeping of their gardens; and the habits of both parties accommodating themselves to this improved state of things, would be the ground on which to rely for its continuance. In this view of the subject, the future progress of gardening depends on two causes; the improvement of the taste of the patrons of gardening; and the improvement of the science and art of practical gardeners.

CHAP. I.

Of the Improvement of the Taste of the Patrons of Gardening.

7711. Improvement is the characteristic of civilised man, and implies progressive advances. Men rest satisfied with what they have, when they know of nothing better; and therefore, one of the first sources of improvement in the taste of the patrons of gardening, whether of the tradesman who has recourse to the public market, or the private gentleman who is in possession of a garden, is the increase of knowledge. The wealthy tradesmen of Dublin and Edinburgh should look into Covent Garden market in London; and, not to mention fruits, and forced or exotic productions, let them compare the cauliflowers and salading of the three markets. Those who have once acquired a taste for such salads of endive as are afforded in the London market throughout the winter, would not very readily reconcile themselves to the aceticarious productions of Dublin and Glasgow during that season.

7712. The ignorance of the proper mode of cooking vegetables, and especially of dressing salads, which exists among the middling classes, is another retarding cause. A French laborer, out of a few leaves of dandelion and wild sorrel, which may be gathered by the hedge-sides anywhere, and almost at any time, will produce, merely by the aid of the common condiments, what the wives of the greater number of respectable British tradesmen have no idea of. There can be no great demand for a thing, of which the use is not thoroughly understood; and, therefore, an improvement in the knowledge and practice of cooking must take place among a certain class before much can be expected in the quantity, kind, or quality of the gardening articles which they commonly consume.
7713. The more general use of dessert fruit among the middling classes, is another requisite wanting for the improvement of horticulture in Scotland and Ireland. If fruit, physiologically considered, is less wholesome after dinner than before it (which is questionable), it is at least more so than where drinking is substituted in its place. To prolong the period of eating, and the conversation of female society, are not only objects which afford immediate satisfaction; but, by moderating the use of stimulating liquors, tend to ensure future health. But, even in England, where a dessert is universal among the independent class, there is a great want of nicety of taste: fruit is valued by many only as a symptom of the presence of wine: others contentedly use pears and plums that would be rejected at the most common French déjeuner; and many rest satisfied with melons and grapes, who, at almost no additional expense, might have pine-apples. Wherever the litter of four horses is at command, pine-apples may be grown in Baldwin's manner (2649. and 2698. &c.) with very little trouble to the gardener, and, indeed, at much less trouble than trying to have very early cucumbers or melons. But why speak of pines, when not one family in a hundred are properly supplied with mushrooms, which ought to be on the table in some form, every day in the year. On a small scale, the grand secret is, to employ a gardener who knows his business; and to direct his attention less to raising ordinary productions at extraordinary seasons, than to raising first-rate crops of everything in due season. On a larger scale, all ordinary and extraordinary things should be attempted that art and wealth can accomplish.

7714. A taste for fine flowers and rare exotics must be preceded by some knowledge of plants, or a taste for scientific botany, and the history, geography, and uses of plants. These branches of knowledge may be considered as gaining ground. A good deal also depends on the fashion of using flowers as chamber ornaments, and on having green-houses attached to dwellings; both are most agreeable and rational luxuries; and it is much to be desired that a taste for them was more general, especially in provincial towns, and in the cities of Scotland and Ireland.

7715. The taste for planting has attained a greater height, during the last twenty years, than any other department of gardening; the beneficial consequences of which are already powerfully felt in Scotland, and the exposed parts of England. An essential requisite in this department is attention to the future management, thinning, and pruning of plantations.

7716. The taste for landscape-gardening has been nearly dormant in England, during the last thirty years; in Scotland it has been more active, but not of the purest kind; little has been done in Ireland generally, though there are some patriots there, who have been active in improvement. A taste for deer-parks is not common in Scotland; and rare in Ireland. A park in Scotland is a grass field; and what in that country corresponds with the park of a mansion in England is a number of green enclosures lying contiguous to each other, and surrounded by strips or rows of trees. In Ireland a mansion and park is a naked house, in a naked grass field, surrounded by a stone wall. There are exceptions in both countries; and many lawns or sheep-parks in Scotland of considerable beauty. Besides, a union of pasturable wooded enclosures, as a park, may be very well defended on the principle of utility; but there can be no defence of the naked parks of Ireland.

7717. The taste for public gardens, as promenades and botanic gardens, seems on the increase; but unfortunately these are seldom founded on a sufficiently secure basis. The funds of the recently established botanic gardens have been generally raised by the subscriptions of a certain number of individuals, to whom, and to certain annual subscribers, the garden is alone accessible. Perhaps it would be better, if, as in the case of public promenades, the funds were raised by the whole town or community, and the garden thrown open to all, like that of Paris. Public umbrageous promenades, either equestrian or pedestrian, are very desirable additions to all congregations of houses.

7718. Choice of a gardener. Very much of the comforts and pleasures which a private gentleman derives from his garden, and garden-scenery, depends on the qualifications of the gardener which he employs to manage them. It was formerly the practice, in books of gardening, to give directions to gentlemen how to choose a gardener. These might have been of use when the qualities desired differed little from those sought for in a common laborer; such as sufficient strength and health, and good morals, disposition, temper, &c. But every master can judge of these and other similar points; and for any gentleman who has not a knowledge of gardening to go further, would be more dangerous than useful. We are clearly of opinion, that in almost every case the best mode is to apply to a respectable nurseryman; to describe to him the sort of garden and garden-scenery to be managed, and the sort of productions desired, and to rely on his recommending a fit person for accomplishing the intended objects. If this person should not turn out so well as was expected, the nurseryman will be in some degree responsible for his conduct, and will feel doubly anxious to replace him by a more competent person.
Book II. 

EDUCATION OF GARDENERS. 1135

Of the Education of Gardeners.

7719. By education is generally understood that portion of knowledge which is obtained at schools; but we shall here use the term in a somewhat more extended sense, and consider it as the means which may be employed to render man competent for performing the part which he undertakes to perform in life with increased satisfaction to himself and others. Education may thus be considered as extending to everything which operates on the body or mind, from the earliest period of our existence to the final extinction of life. With this object in view, we shall consider in succession the professional, intellectual, moral, religious, physical, and economical education of gardeners, previously submitting some general remarks.

Sect. I. On the degree of Knowledge which may be attained by Practical Men, and on the General Powers of the human Mind, as to Attainments.

7720. The knowledge of languages, history, geography, arts, sciences, and literature, which a gardener daily occupied with his profession may acquire, provided he begins at the commencement of his apprenticeship, and continues to employ his leisure hours in reading till he is twenty or twenty-five years of age, is by no means inconsiderable: not that he can, or need become learned; but, if desirous, he may become generally intelligent; render himself fit, as far as conversation is concerned, for good society; prove instructive and entertaining to others by his conversation; and provide a reserve fund of enjoyment for himself, by laying up a store of ideas for reflection in misfortune, disease, or old age.

7721. The terms knowledge and ignorance are entirely relative: the knowledge of a modern chemist's porter would have subjected him to be hanged and burned in the days of the first popes; and any bricklayer's laborer who reads the London newspapers, has more correct ideas on the principles of political economy than nine tenths of the nobility in Russia and Spain. It is impossible to set limits to the knowledge which may be obtained by those who are destined even to the most severe and constant labor. The intelligence of the miners in Scotland and Sweden may be referred to as proofs. The miners at Leadhills have a room of library and reading society; and the works they make choice of are not only histories, voyages, travels, &c. but even works of taste, such as the British classics, and best novels and romances. The degree to which knowledge will prevail among all class of laboring men, will depend jointly on their own ambition; on the demand for, or reputation in which, knowledge is held; and on the opportunities of acquiring it. A dull, stupid person, with little native activity, will never desire to know more than what enables him to supply the ordinary wants of life. Where the workmen of any art are required to have technical knowledge of any particular kind, they will be found invariably to possess it. Thus carpenters and masons require some knowledge of the mechanical principles of architecture, and working engineers of the strength of materials; and these kinds of knowledge are acquired by them without an hour's interruption of their daily labor: on the contrary, the habit of evening study renders them more steady, sober, and industrious than other workmen; than bricklayers and paper-hangers, for example, whose employments require much less intellectual skill. If every cook-maid, before she could obtain a first-rate place, were required to be able to read Apuleius Redivivus in the original tongue, there would be no want of learned cooks; and if no gardener could obtain a first-rate situation who had not written a thesis in Greek, or who had not made the tour of Europe, there would soon be found abundance of gardeners so qualified. A Caledonian, when he comes to the low country, soon acquires the English tongue, and if he has been taught Latin, thus knows three languages. The servants at the inns on some parts of the Continent, frequented by different nations, often acquire a moderate knowledge of three or four languages. A late custom-house officer on the island of Cronstadt spoke and wrote ten languages; and the bar-maid, at the hotel (de Londres) at which we lodged in Moskva, in 1814, could make herself intelligible in Swedish, Russian, Polish, German, French, Italian, and English.

7722. The certain way of obtaining anything is to be impressed with the necessity of possessing it; either to avoid the evil of being without it; to satisfy the desires of others as to ourselves; or, our own desires. There is scarcely anything that a rational man can desire that he may not obtain, by maintaining on his mind a powerful impression of the necessity of obtaining it; pursuing the means of attainment with unceasing perseverance, and keeping alive that enthusiasm and ardor which always accompany powerful desires. Even the most extravagant desires, when sufficiently powerful, are often gratified. To attain eminence, as a literary character, natural or experimental philosopher, mathematician, divine, lawyer, or physician, it is only necessary to have a powerful desire for that kind of eminence, and to apply unconcealingly to the subject, and to that alone. All may not acquire, by the same degree of labor, the same degree of eminence; but any man by labor may attain a knowledge of all that is already known on any subject, and that degree of knowledge is respectable; what many never attain to, and what few go beyond.

7723. The grand drawback to every kind of improvement is the vulgar and degrading idea that certain things are beyond our reach; whereas, everything is attainable by the employment of means; and nothing, not even the knowledge of a common laborer, without it. There are many things which it is not desirable to wish for, and which are only desired by men of extraordinary minds; but let no man fancy anything is impossible to him, for this is the bane of all improvement. Let no young gardener, therefore, who reads this, even if he can but barely read, imagine that he may not become eminent in any of the pursuits of life or departments of knowledge, much less in that of his profession: let him never lose sight of this principle, that to desire and apply is to attain, and that the attainment will be in proportion to the application.
Sect. II. Of the Professional Education of Gardeners.

7724. In order that a professional man should excel as such, every other acquirement must be kept subservient to that of his profession. No branch of knowledge should be pursued to any extent, that either of itself, or by the habits of thinking to which it gives rise, tends to divert the mind from the main object of pursuit. Something, it is true, is due to relaxation in every species of acquirement; but judicious relaxation only serves to whet the appetite for the vigorous pursuit of the main object. By the professional education of gardeners, we mean that direction of their faculties by which they will best acquire the science and manual operations of gardening: and we shall suppose the young man to be instructed, to have no other scholastic education than some knowledge of arithmetic, and the first problems of geometry and land-surveying. The sort of garden which ought to be the scene of the days of apprenticeship should, if it can be so foreseen and arranged, be that which the learner is ultimately intended to possess or manage. As the great majority of young men who learn this art, are intended for serving-gardeners to private families; a private garden, where every department is respectively conducted, is the best to begin with. Here, or in any other garden in which he may be placed, he will have to learn the names of things, their uses in gardening, how to use them in the best manner singly, and how to combine their use in performing the different operations of gardening.

7725. The grand foundation for every kind of acquirement, is the cultivation of the faculties of attention and memory. Unless we pay attention to what is addressed to us, whether by the eye or the ear, it is impossible we can remember, because the sight or sound has made no impression on the memory, and without memory, there can be no knowledge.

7726. Many pass through life without seeing or hearing anything but what immediately concerns their avocation. Something for a person a walk out and return without being able to describe, or even mention, any one thing he has seen; or to read a newspaper without being able to tell what he has read, farther than to give some vague idea of the subject. All this is the result of neglecting to rouse and exert the faculty of attention; or of limiting our attention to one single object or class of objects. One of the first things, therefore, that a young gardener should do, is to cultivate the faculty of attention, which he may do every hour of the day, by first looking at an object, and then shutting his eyes and trying whether he recollects its magnitude, form, color, &c.; whether he would know it when he saw it again, and by what means he would know it. When he goes from one part of the garden to another, or is on a walk or journey, let him pay that degree of attention to everything he sees and hears, which will enable him to give some account of them when returned from his walk or journey; and let him try next day, or some days afterwards, if he can recollect what he had seen then, or at any particular time and place.

7727. The attention must be exercised systematically, in order not only to impress the memory, and enable the observer or hearer to recollect objects, but to describe them. A thing or a discourse must be attended to, not only as a whole, but as a composition of parts; and these parts must be considered not only as to their qualities of dimension, color, consistency, &c., but as to their relative situation and position.

7728. To be able to give an account of a town or village, for example, the first thing is to get a general idea of the outline of its ground-plan, which may be done by looking from a church-tower or adjoining hill; next, to be attentive with regard to such objects as woods, fields, and woods, &c., being considered as parts; in it, and in what quarters; next, the direction of the leading street or streets must be noticed; then the intersecting or secondary streets; the principal public buildings; the principal private ones; where the lowest houses and narrowest streets are situated; and what is the character of the greater number of houses composing the whole assemblage.

7729. To be able to recite to mind or to describe the figure of any person before us for the first time, it is necessary to attend to height, either absolute, by estimation in feet and inches; or comparatively with our own, or that of any other person or persons present at the time; to figure or shape generally, as whether tendency to excellence or defect; then to hands and feet, gait, manner, &c.; and, above all, to the form or outline of the countenance, the complexion, and other details of the face. One untutored person looking at another with a view to recollect or describe him, would only stare; but an attentive and systematic observer would survey both the party generally and in detail, and in such an order as would readily occur to the mind on reflection. He would not, for example, after estimating the height, proceed next to the color of the eyebrows, but would take the breadth and shape, as more congenial to the accustomed train of ideas.

The young gardener will apply these hints to recollection of parks, pleasure-gardens, walled gardens, hothouses, and also to the study and recollection of individual plants.

7730. To be able to recollect and relate written or oral discourses, the same general principles will apply; the first thing is to attend to the object in view, and next to the order or form in which the whole is presented; and then to recite the same arranged, as well as delivered, or the main idea of the whole.

7731. The study of natural history and drawing are well adapted for improving the faculties of attention and memory. The former by its systematic arrangement, and the precision of its details, tends to habits of order, accuracy, and distinctness; and to the ready recollection of natural objects; the latter contributes to the same extent, and also to the recollection of objects in groups or combinations. Hence, the importance of a gardener's attending to botany, zoology, and drawing, even with a view to general improvement, independently of their special utility in his profession.

7732. The recollection of names and numbers is a more mechanical process than the recollection of objects. Names are either descriptive, that is, when they consist of a word, or are composed of words which describe something of the object to which they are applied, as Longtown or Hillhouse; or they are arbitrary, meaning nothing, or nothing now known or definable, as William, Thomas, &c. The first are of easy recollection, because, even though the object may never have been seen, its image may be presented to the imagination by the name, as a town of great length, and a house on a hill top; the second are only to be recollected by seeing the objects to which they are applied, and then associating in the mind the name with the thing; or by seeing the description or portrait of the objects, and associating the name with these; or by finding a resem-
blance between the new name and a known name, as William, wild yam; Thomas, to miss, &c.

7733. The principal names which a gardener has to recollect are those of plants; to assist him in this knowledge, the etymologies of all the generic names, and of the specific names, which are substantives, is of great advantage; the ordinary specific names being adjectives, are easily understood and recollected. The generic names of plants and animals are of three kinds; those composed of words indicating something of the nature, without allusion; it is easy to imagine his wife reproaching him with the last circumstance, while he points to Gordonia Lasianthus. All those names, whether of science, or those which occur in the common intercourse of life, as of persons and places, are to be recollected on the same principle; that is, either by the natural resemblance of the image, or by the resemblance of its other name already known, or by forming an association between it and some known or familiar visible object; and the more ludicrous is the association, the better it will be recollected. In forming these associations, it is essential that the object employed to aid the memory be one capable of being seen; to associate any particular object with a sound, smell, touch, or taste, would give little aid to the memory; and to associate it with abstract nouns or ideas, none at all. "If I am told that the Dutch merchant Schimmelphenninck was a very wealthy or religious man, that will not assist me in recollecting his long name; but if I say to myself there is some resemblance between Schimmelphenninck and skim-milk-pen-and-ink, the resemblance may enable me to do so; or if I have recourse to a Dutch dictionary, and discover that schimmel ingrey, and phenninck a penny, I have grey-penny, as a synonym, which, with the operations the mind has undergone in getting at it, will most probably impress the original name on the memory. If a Highlander tells me his name is Macpher-son, I at once identify it mac-pearson — mac parson, — son of a parson — son of a Catholic priest and a Highland maid."

7734. Figures may be recollected by gardeners with readiness and certainty. For all numbers not exceeding 24 they have only to associate the figure with the name of the corresponding Linnean class, or with one of the plants of it. Thus, if a lad in a nursery is sent to the fruit-tree ground for plants of number 19 and 21 of pears, he has only to think of Syngenesia and Monoezia. For all numbers exceeding 24, and under 250, he may make use of the terms of the first ten orders, in addition to the 24 classes; and thus, No. 241 will be Cryptogamia monogynia, 249 Cryptog. enneagynia, 208 Gynandria octogynia, and so on. To any one but a gardener or botanist, this mode of recollecting numbers has no advantages over any ordinary system of artificial memory; but as there can be no gardener to whom these classes and orders are not perfectly familiar during the whole period of his life, or at least of his practice as a gardener, to him it is superior to all the artificial systems. It is easy to add to the certainty of remembrance by associating the figure of any known plant or plants belonging to the class or order; thus, for 24 he may think of Osmunda regalis, for 245 Osmunda regalis and Daucus carota, or a fern-frond and a carrot-leaf, for 16,213 he may think of a nosegay composed of a Canna glauca, Narcissus triandrus, Olea fragrans, and Rosa provincialis, or he may fancy himself planting these plants in a row or in a pot. If a gardener rides through twenty turnpike-gates in a day, he may recollect the pass-number of them all. He has only, in passing through them, to place a pot of the indicating plants on each of their gate-posts.

7755. Numbers may also be recollected by gardeners by their going through the operation in imagination, of cutting them on a number-stick, either by the common (fig. 160.), or by Seton’s method. (fig. 161.) Names may be recollected in like manner, by their going through the operation mentally, of writing or printing them, or writing them in some particular hand, or imagining how some particular friend, with whose handwriting they are acquainted, would write them. They may be supposed to be written on any scrap of paper, or against the day of the month in a common pocket-book, or what is preferable, after the last entry made in the pocket memorandum-book (7741.), to be afterwards described.

7736. The memory, both as to figures and words, may also be materially assisted by studying the postures of the human figure, corresponding to the first ten Italic numerals, and the letters of the Roman alphabet. Plates of these are to be had in the juvenile libraries. Some useful hints on the subject of memory will be found in Feinagle’s work on the subject, and especially in a tract by Jackson, in which Feinagle’s system is greatly improved; but the machinery of both systems, though they enable a student to recollect an astonishing deal in a short time, yet, like other complicated machinery, it soon goes out of order when not in constant use. It is, therefore, unfit for practical men.

7737. The uses of things and their history, is the next thing which a gardener has to acquire. The uses of the implements, tools, utensils, and machines of gardening, he will acquire by manually exercising them in performing the labors and operations of gardening under the direction of his master. He should not only know how to use them, but the best manner of using them. The history of each implement, or machine, derivation of its name, why one form is preferable to another; in short, he should know the rationale of the formation and operation of all of them. The essential part of this he may acquire by reading Part II, of this work, and the rest from the study of the principles of mechanics, and by conversing with intelligent carpenters, millwrights, and engineers.

7738. The uses of the commoner garden plants he will find in the third part of this work, Books I., II., and III., something more he will find in Book IV., and for the rest he must have recourse to books on cookery, medicine, chemistry, and farming, which go more into detail. Much information on all the arts con.
nected with the vegetable world will be found in our **Encyclopaedia of Plants**, and in the **Encyclopaedia of Agriculture**.

7739. The study of systematic and physiological botany must go hand in hand with practical acquirements; for which, and also for forming an herbarium, he will find general information in Part II. Book I., and for more minute details, he may consult the authors there referred to. Some idea of vegetable chemistry and geology he will obtain from Books I., II., and IV. of Part II.; and also of the different insects and vermin which are enemies to gardens and garden-productions. The study of landscape-gardening, as being the highest part of the profession, should not be attempted till the apprentice has made himself master of the three departments which precede it.

7740. A knowledge of the weather and the seasons, so as, in some degree, to be able to predict them from signs, is an important part of a gardener’s acquirements. Our observations in Part II. Book II. will aid him in this study, and he should also keep a weather-book, or naturalist’s journal, such as we have already suggested. (2349.)

7741. A pocket memorandum-book, for taking notes of everything interesting, whether professional or general, is a useful help to the young gardener. He should begin this sort of memorandum-book with his leaving school; and he will probably find it useful to continue it all his life after. Its size should be small octavo, to suit the pocket; it requires no ruling, but a line across the page half an inch from the top. In writing on one page, the opposite one should always be left blank for corrections and additions, for sketches, or for taking down temporary memorandums in pencil. The following may be considered as a specimen, in which it is to be particularly observed, that a margin is left on the written page, on which margin each article is begun with a word written or printed in large letters. These words, thus conspicuously placed, serve as indices to each article, and in future reference will be found of material use, as they can be glanced over like the words in a dictionary. Any thing to be inserted, should always be done instantly, or never later than the same day. If it is done out of doors, it may be written on the blank page in pencil, and afterwards copied on the opposite page in ink.

**Pocket Memorandum-Book of J. Gott, Apprentice, at Aubrey Hall. — January 27th and 28th, 1821.**

27th. These were covered with drill hand-glasses, and the croq. is now, June 24, fit to gather.

PEAS. — Last night’s frost and this day’s sun have killed the peas in the south border: but those now in the north side of the waddled hedges escaped, being shaded from the sun.

LIZARD. — Caught a new species, and took it to Twigg.

It had no tail, which convinced him it must be a distinct species.

28th. ROSES. — Idea of a cone iron tree, covered with any of the climbing roses, all over inoculated with monthly vases.

PARSNIPS. — Gurkin O’Doolittle caught distilling partner whiskey in the tan-shed; discharged without a character. His still two watering pots placed top to top, and closed with a wet cloth: the top kept shouldering water on it.

NEW IDEAS. — Terriold Joss, the parson, called; says there are two ways of getting new ideas, by shuffling what ideas we have together, like a pack of cards, (which is to be done by a free glass of wine, opium, or tobacco,) when new combinations may occur to the mind accidentally: or by a studied selection of ideas suitable to the subject, which it is desired to invent, which can only be done by scientific persons, as Sir H. Davy in his invention of the safety-lamp.

Mon. — Cobbler’s name White, lives two doors from the Cat and Fiddle.

7742. Apprentices are often required to keep a written journal of work done in the garden for their own use, and this may be advisable in cases where no regular books are kept by the master; but where such books and tables are kept as we have recommended (2338. to 2330.), the apprentice performing his part in making entries in, and daily seeing them, need keep no other books for his own improvement than a naturalist’s kalendar (2349.) and the journal or memorandum-book just described. In the last he can enter such facts belonging to gardening as are commonly entered in gardeners’ journals.

7743. Progress when a journeyman. An apprentice, besides studying his art in the garden of his master, should, as often as may be, visit those of his neighbors, and observe what is going on there. His apprenticeship completed, he should move to a different part of the country, performing the journey leisurely on foot; botanising and collecting insects and minerals, and visiting every distinguished garden on his way. When he settles, it should be in a different kind of garden to that in which he was before, and there he should continue a year, and then remove and travel to another part of the country, and settle there a year, and so on as already suggested (7380.), till he attains his twenty-fifth year, when he may undertake the situation of master. During the whole period in which he is journeyman, he should be steadily and unceasingly employed in improving himself, first in his own art, and the branches of knowledge, as botany, natural history, chemistry, weather, &c. on which it more immediately depends; and next, if his ambition permits, on general subjects of literature, arts, and sciences.

**Sect. III. Of the Intellectual Education which a Gardener may give himself, independently of acquiring his Profession.**

7744. Self-education may be carried to a greater extent by a gardener than by almost any other artisan. No gardener, in our opinion, ought to be employed as a master under the age of twenty-five years. Suppose him, therefore, to be put an apprentice at
fifteen, he has ten years in which to acquire his profession, and generally to improve himself. In that period he may not only acquire his profession, but, according to the extent of his ambition and application, a considerable degree of knowledge on almost every subject. Everything, as we have more than once observed, depends on his ambition; without this he will not even acquire his profession, and at all events will find no leisure time for any other kind of improvement. When we consider, however, that the labor of a gardener is not severe, and that it is only during the hours of daylight, the time he has for self-improvement is very considerable. It may surprise some when we state, that this time equals (taking the whole year), that employed in study by professional students at colleges. A gardener, in the shortest day, begins work at eight o'clock and leaves off at four o'clock; which, allowing two hours for breakfast and dinner, gives six hours of labor; in the longest day he works only ten hours, and therefore it will not be far from the truth to consider eight hours per day as the average duration of his labor throughout the year. Dividing the twenty-four hours which compose the day in three equal parts, we have eight hours for rest, dressing, and undressing; eight hours for labor, and acquiring the practice of gardening; and eight hours for refreshment and study. On comparing this time for study with that which is usually devoted to it by young men at college; not the generality of young men, but those even who attain to eminence; we will find the difference very incon siderable.

The student requires the same time for rest, and at least two hours more for dressing and undressing (say ten hours); for breakfast he requires an hour; dinner and tea, at least three hours; and for exercise (which if he neglects he will soon be unable to study at all), at least two hours; in all, for exercise and refreshment, six hours; which added to ten of rest and dressing, gives eighteen hours, leaving exactly the same number of hours for study which every gardener has, taking the average of the year. It is true the eight hours of the gardener are subject to the time employed in eating; but that may well be considered as compensated by the knowledge of botany he acquires in the garden during his hours of labor. Add also, that the gardener may (unless his health forbid) draw still more time than we have mentioned from the hours of sleep; we think it will not be denied, that, taking all circumstances into consideration, he has as much time as studious men, taking the average of the year, usually devote to study.

7745. The branches of education best deserving a gardener's attention are next to be considered. As one branch of knowledge is as much as any person ever does or can excel in, and as that branch, in the case of every professional man, ought to be his profession, it seems to us that a gardener ought not to attempt to excel in any other branch of gardening; that he must necessarily know the degree that circumstances may permit, with the whole cycle of human knowledge. If he attempts anything else, it is impossible, isolated as he must be, in comparison with others who study the same subject among the abundance of books and fellow laborers, that he can attain to the highest degree of eminence. It is impossible, for example, that he can arrive at great perfection, even in the study of botany, from not having an opportunity of consulting the herbariums and books which are only to be found in the metropolis. He may, however, and ought to, attain a respectable degree of knowledge, not only in botany, but also in chemistry, mechanics, and engines, only for example to enable him to choose the best plant to his taste or convenience, to introduce it to its place in the Linnean system, and describe scientifically any new production. But that he should be expert at chemical analysis, dissection of animals, solving problems in any of the higher branches of mathematics, or excels in painting, music, or poetry, is what we by no means propose, or think practicable. But as these are cultivated, we are convinced he may know something of all those subjects, and of all others on which there are published books.

7746. The source from which he is to derive his general knowledge, it may easily be conceived, is chiefly from the Encyclopaedia Britannica, from professional studies, public lectures, and reading wherever he has an opportunity of conversing with them; artists, artisans, and manufacturers of every description; and also manufactories, engines, mines, dock-yards, and all other works displaying human skill. But the grand source is books, and the question is how a journeyman gardener, whose wages are often less than those of a common laborer, is to procure them? Our answer is, borrow them; and make it a fixed rule to purchase no books excepting grammars, dictionaries, and other elementary works; and of these used or cheap copies. The head gardener will always be able and willing to lend his apprentices and journeymen a certain number of books; and the patron under whom they serve, will generally be found equally liberal.

7747. The sorts of books desirable to borrow, independently of those connected with the professional requirements, such as treatises on Chemistry, Zoology, Mineralogy, &c. will depend on the degree of ambition and talent of the gardener. But he may be dispensed with the Encyclopaedia Metropolitana, and the Cyclopaedia. One systematically instead of alphabetically arranged would be the best; but as most country libraries are now stocked with the Encyclopaedia Britannica and Rose's Cyclopaedia, these must be taken till a well executed one on the plan of the Encyclopaedia Metropolitana, how publishing (but badly executed), may be had in every general library.
may be said to resemble pouring water on ground with a hardened surface, in comparison to pouring it on soil which has been loosened with the spade. 7749. English grammar and a foreign language are suitable studies to commence with. Another excellent way of getting into the mind of the reader is to study historical and accurate data. What is necessary in our case is to join the study of languages, those of arithmetic and geometry. These, with a portion of general reading, some species of personal accomplishments, and the requisite professional studies, are all that we have an opportunity to commence with, and this only in a certain order to be afterwards described. 7750. With respect to personal accomplishments, we would have dancing, fencing, boxing, wrestling, the infantry manual exercise, whist, backgammon, chess, the flute, and violin, attended to as far as opportunity permitted; considering dancing, boxing, and the violin as the most essential objects. In most countries, particularly in France, and in many parts of Italy, there is no master of the violin or the flute who does not receive pay from some of the servants in a great family, at an easy rate. Swimming and horsemanship should not be neglected; if opportunity offers. The acquisition of some knowledge of some or all of these accomplishments may not at first make any great impression on the mind of the boy; but, if he has obtained the utmost amount, or of relief from ennui when alone. Dancing and the manual exercises are particularly useful as improving the gait, and habituating to good postures both in standing and sitting. To a man who has no other resources for advancement in life than such as are personal, every exterior accomplishment is of the utmost importance. These remarks will apply equally to many other countries, and it is impossible to determine whether there is any young man who does not, to a certain extent, possess most of these accomplishments as it were accidentally? Why then may he not improve them by art, if opportunity offers; or, if they are of use, should he not seek to take early steps to extend his knowledge in this department. 7751. If a study be in everything else, much depends upon the division of time; there is no regular and constant, and as there is only a certain portion of the twenty-four hours which a gardener can devote to study, everything depends on his employing every moment of that portion. To be convinced of what is acquired, say two persons commence walking along a road in company; then let the one stand still for half a minute while the other walks on; at the end of the half minute the distance at which the former will find himself from the latter will be found astonishing. Again, suppose them walking together, and that one, instead of walking along the road with the other, deviates and diverges from it—the other continues straight on, and will, after a little time, be at a distance from which the former could not have been seen. The same remark will apply to many other cases. Whether there is any young man who does not, to a certain extent, possess most of these accomplishments as it were accidentally? Why then may he not improve them by art, if opportunity offers; or, if they are of use, should he not seek to take early steps to extend his knowledge in this department. 7752. To do in the economy of time, it is desirable to form some plan of study; where there is no regular plan much time is lost in hesitating what to begin with; and both lost and misapplied by fatiguing the mind with too long intense application to one thing; by which means a proportional relaxation is required, and the mind, being irregularly charged, will be less faithful. By a well ordered pre-disposition of studies, the mind will be kept in the most agreeable state of reflection. If the plan were never so well thought of, the one study becomes a relaxation as it were from the other. We shall here suggest a general plan for a young gardener's employment of time during the few years he has to pass previously to becoming master, and learning the details in his way of life. We by no means pretend to be equal to those; but the grand point is to fix on some plan, and to adhere to it strictly. 7753. Plan of study for languages. We shall suppose the apprentice, and indeed every gardener under thirty, to rise at five o'clock throughout the year; a necessary habit in the gardener, both for the hot-house, and for the garden. He will eat his breakfast nearly an hour later, and a good one, and walk in the morning before he goes to work. These we would devote to languages throughout the ten years; on no account would we study anything else at that time, and on no account would we study any language during the rest of the day. Latin and English grammar may be taken on alternate mornings till the latter part of the second year. Afterwards Latin may be taken two mornings, and Greek the third morning. In two or three years the fourth day may be devoted to French; and in the seventh year, or earlier, according to circumstances, Latin, Greek, French, German, Dutch, and Italian may be taken in succession, one morning a week. The object is to acquire a knowledge of Latin and French to translate them with ease; and of the other languages to be able to make out their meaning by the occasional help of a dictionary. There is nothing to hinder any person of even inferior organisation, to attain this knowledge in ten years, at the average rate of one and half hour's study every morning. The only thing is not to succumb to the temptation of a single morning's sleep; or, if they be obliged to be absent from home, or during a journey, a grammar or any polyglot book, such as a Testament or a Commentar, may be carried in the pocket. 7754. Progress is gradual. It is impossible to gain any end either in self-improvement or any thing else at once: all art is gained by labor, and nothing is lasting but that which advances by degrees. The pronunciation which we generally consider the most correct of languages confers on the possessor, whether in general reading, or in reading foreign books, is invaluable, and amply compensates the trouble requisite to acquire them. To any person going abroad for profit or improvement, they are essential. It is a common thing to suppose, that a certain long number of years are requisite to acquire Latin, which may be in some measure true of those who have not busied themselves with it; but, with a well grown and voluntary learner the case is widely different. We have known men in this country acquire one or two languages, after having attained their fortieth year; and the thing is quite common among migrating tradesmen on the Continent. 7755. Progress is gradual. If by pressure of the occasion, and at any time, through business or over-sleeping, but a few minutes can be got in the morning, still these few ought to be applied in the usual channel; even half a minute is worth something, for in that time a noun may be looked over, or a rule read and reflected on during the walk to the place of working. If no time is left, even while dressing, a dictionary may be opened, and a word looked at, and then, as work goes on, the mean time is utilized, and at last, when work goes off, there is an opportunity of attending to the dictionary. 7756. Books on grammar. In connection with this, we shall mention that Cobbett or Lindley Murray may be selected for the English; and for the other languages, any that can be got cheapest; the last remark will apply also to the dictionaries. To impress rules and words on the memory, read them aloud, sing, or chant the words, putting them down by rote. As many languages as we can, and the most languages we can, applying to a subscriber to the Bible Society, he will procure a New Testament in any living language, and also in Latin, Greek, and Hebrew, for two shillings or half a crown. Used copies of the Jesus Lutheran of Commenius, containing Greek, Latin, French, &c. are to be had even cheaper. 7757. Books on botany. For general studies, we shall devote to botany for the first three years, and the seven years afterwards to botany and other branches of natural history, gardening, and farming books. Thus the early part of the day is disposed of for the whole ten years, subject to arranging for evening. For evening, we shall devote to botany, as it does not all depend on the will of the student; thus lectures can only be attended when and where given; and those who may have undertaken to give instructions in fencing or fiddling, must be received at such evening hours as suits their convenience, &c. We would, however, never break in on the day-studies with these accomplishments; and as far as possible devote two hours at some time of every working-day evening, during the first three years, as follows: of the first evening to drawing plans and architectural subjects; the second to arithmetic, mensuration, and land-surveying; the third, to

7761. The subject of morals (mora/es, Lat. manners) regards the conduct of man towards others; that of religion (religio, Lat. devotion, devoted to), his opinions as to God or the nature of things; and that of physical education (physica, Lat. the knowledge of nature) instructs him in the art of preserving health.

7762. Morality and religion are usually treated as depending on each other; the latter is considered as the principal foundation of the former, and man is taught to be sober and honest, not only to avoid the punishment awarded by the laws of his country, but to avoid still greater punishment in futurity. But morality may and does exist apart from religion; for truth and justice, honesty and humanity, are essential to the existence of regular society. Debauchery of every kind is attended with the loss of reputation, and more or less of bodily health; those who despise, and affect to treat with contempt or ridicule, the opinions of the respectable part of society, are themselves despised and excluded from society in return. In the intercourse of society, a man always receives according as he gives; and as he treats others so is he treated himself. If he wishes to be dealt with honestly, he must be honest; and if he wishes to be respected by respectable men, he must respect them, and their conduct and principles. In short, independently of religious motives, it is necessary to be moral, in order not to be disreputable; and worth while to be highly so, in order to ensure confidence and respect. Whatever theory therefore the young gardener may adopt, there is only one practice which he will find to answer his expectations; and that is, the strictest regard to truth, honesty, sobriety, decency, and purity in himself; and respect for others, in proportion as these virtues appear in their conduct and conversation.

7763. The moral law of all countries is essentially the same; because, in the rudest forms of society, it is found necessary to enforce justice and honesty; but among rude nations, and even among those in a comparatively advanced state, the more refined laws of morality are neglected. Thus in Russia, where the people, from the boor to the czar, are the most religious in Europe, it is not discredit to a gentleman to have a prostitute in the house; the papers from another illustrious and polite shop (Lipton's Moscow, xxxix), but in a refined and luxurious state of society, such as that in Britain, the enjoyment of every individual depends not only on a strict, but a refined morality; and men must not only be civil, but polite. True, adroitness may be considered the ornament or finish of morals or manners; and though it is commonly thought to belong chiefly to the higher classes, yet it will be found both attainable and useful in a high degree, by every class, and by none more than the gardener. Polite and amiable conduct, like a good figure and address, recommend themselves at sight, and make at once an impression in favor of the man who possesses them. M. W. Montague observes, "is a sort of current coin which costs nothing and buys everything." The greatest genius and abilities will never procure a
1142 STATISTICS OF GARDENING. PART IV.

man advancement, without a good address. We recommend the perusal of what Lord Chesterfield has written on the subject, guarding against those slips of the pen where he seems to recommend im-
purity and deception. If these suit the character of a modern ambassador, they are practices which a poor
man may afford to fall in.

7765. The foundation of all true politeness is a desire to please others; though some mistake it for a dis-
play of their own acquirements; and others, a craving aequaness of the opinions of others. The two
last errors are to be avoided, the first as immediately, and the second in a short time, inquiring contempt.
The first is a defect which every man is, for all things, at no time; and none but the meanest and 
most arrant, is certain of proving offensive. To please others, one of the first things requisite, is to be, 
or appear to be, pleased ourselves. A man may show his pleasure or displeasure, by his action, by his 
speech, and by his features. An easy, graceful, and yet manly action, is to be attained by the practice of 
discipline, exercise, and rule of life. He that is prompt, exact, requiring exactness in himself, and attending to the language of ladies and gentlemen, frequenters of polished society; and the features of the 
face may be set to satisfaction, discontent, anger, or ill temper, according as either of these states of 
mind, or of a mind in a state of agitation, is put in the garden. There are so many different passions and 
his apprenticeship, almost anything may be done with them, as may be proved by the ease of comedians.

A gardener's object should be less the power of varying them, than of giving them a set expressive of 
animation joined to a degree of satisfaction: this medium or central disposition he can occasionally alter 
for the sake of variety. The distinction of the one hand, or circumstance of the other, is but a 
proper degree of animation, and of the countenance which we ought to supply.

We have hitherto considered by the great bulk of mankind as the art of chemistry: and the conse-
quence is, that in ordinary society it consists in tiresome relations, as to the party or their 
affairs; attempts to obtain victory in argument, to display knowledge or acquirements; or something 
which may give superiority over the others present; or of criticisms on the absent; the source of all 
which is an impertinent conversation, which arises, not from talking about any one thing, whether relating to 
ourselves or others. In disposition, the object is to ascer-
tain truth; in conversation, to pass the time in an interesting and agreeable manner. The object of every 
cultural and polite conversation ought to be to please; whatever cannot be said on any subject 
entered on, without giving offense, is not a progression of the first. By common consent, the party will pay 
due respect to the master of the house, as to the president of the assembly; and though all will contribute their share, those rich in talent and experience will naturally con-
tribute the most.

7766. An essential part of politeness is agreeable conversation, and taking part in the current amuse-
ments of the time and place. The art of conversation, like all other arts, is only to be acquired by reflec-
tion and experience. The first thing is to store the mind with ideas on every subject by reading, and as-
pering; and when an anecdote, or story, is delivered next the table, the history, or view of the conver-
sation, in which we happen to be; and the last requisite is to endeavor to discover the precise part and 
quantum of conversation which we ought to supply.

The art of conversation is an instrument by which we 
define our knowledge of the art of conversation, and 
advise them more especially to avoid all subjects that lead to argument and discussion. These are 
demanded little for truth or instruction; because men are seldom convinced by arguments carried on in 
society. No man is willing to be publicly convinced of anything, and especially if he has already, on the 
other side of the argument happens to be younger or of an inferior rank. Men will be willing to be instructed, 
who will not submit to be convinced; and some will consent to receive information, who would feel 
how to have it. Hence conversation, on the score of conversation, and the prejudice of acquirements, 
may both instruct and inform: but even these must be cautious as to the manner in which they correct, 
or contradict, or criticize; lest, as is often the case, they appear more eager to display their own superiority, 
than to improve and oblige the party addressed. The love of self is liable as self-respect. A man in rank, in age, or in any respect, if he is not of the place, or the set, is disposed to 
the fact of being continually under restraint by keeping alive the idea, that the object of all conversation is to please. Three or four young gardeners, all eager for improvement, might practise conversation on this 
principle, by assembling occasionally, and either conversing as equals, or for the sake of variety and im-
provement, assuming characters. Thus, for example, may take the part of the parents of a family; one 
or two as strangers on a visit to them, and the rest as children, and so on. The party might first produce 
that sort of family wrangling and snarling, which commonly occurs at firesides, as the conversation 
to be started; and next, a conversation as it ought to be, or as each gardener would desire to have it 
in his own family.

7767. Whist, chess, &c. For the purpose of being able to join in the amusements of society, we have 
already recommended the study of whist, chess, &c. These are essential personal accomplishments of 
every gentleman and young gentleman, if he wishes to be well understood in Essex so well understood 
as on the continent, and therefore less relied on for passing the time agreeably.

7768. Elevation of manners. There are two things in conduct which the gardener ought most particu-
larly to avoid and subdue, viz., familiarity and coarseness. In these qualities discover themselves either in manner or 
conversation, they are a certain mark of low birth and breeding. A low, ignorant man, if he receives 
the slightest civilities from a superior, immediately conceives the latter has a particular friendship for 
him; and soon endeavors to turn this friendship to advantage, by asking to borrow money or to forward 
himself in any manner. The moment a gardener has given way to this, he must lose all his advantage.

A gardener, if he notices a low familiar woman, the latter immediately concludes he is in love with her; if 
she has daughters, he has come to marry one of them; and at all events, he is a particular friend to be 
offered to and relied on in time of need, who will certainly advance the family in some way or other. Such 
is the case of the deeds of any one who is not readily obeyed by his superiors; and this familiar 
gross selfishness that puts no restraint on wishes that it does not consider grossly criminal; and indulges 
in the most absurd hopes, merely because, if realised, they would tend to their profit.

7769. Whist, chess, &c. For the purpose of being able to join in the amusements of society, we have 
already recommended the study of whist, chess, &c. These are essential personal accomplishments of 
every gentleman and young gentleman, if he wishes to be well understood in Essex so well understood 
as on the continent, and therefore less relied on for passing the time agreeably.

7767. Elevation of manners. There are two things in conduct which the gardener ought most particu-
larly to avoid and subdue, viz., familiarity and coarseness. In these qualities discover themselves either in manner or 
conversation, they are a certain mark of low birth and breeding. A low, ignorant man, if he receives 
the slightest civilities from a superior, immediately conceives the latter has a particular friendship for 
him; and soon endeavors to turn this friendship to advantage, by asking to borrow money or to forward 
himself in any manner. The moment a gardener has given way to this, he must lose all his advantage.

A gardener, if he notices a low familiar woman, the latter immediately concludes he is in love with her; if 
she has daughters, he has come to marry one of them; and at all events, he is a particular friend to be 
offered to and relied on in time of need, who will certainly advance the family in some way or other. Such 
is the case of the deeds of any one who is not readily obeyed by his superiors; and this familiar 
gross selfishness that puts no restraint on wishes that it does not consider grossly criminal; and indulges 
in the most absurd hopes, merely because, if realised, they would tend to their profit.
both of love and hatred, curiosity and communicativeness. Judicious restraint is everything as to overcoming bad or vulgar qualities; a man properly under its influence may be compared to a well-trained tree; and as this figure is familiar to the young gardener, it may be well for him frequently to ask himself, whether, supposing he were a cherry-tree, he would be reckoned one finely spread against a wall or an unpruned standard.

7778. Religion is a subject which we leave every gardener to arrange with his own conscience; only observing, that as it concerns only the man himself, and unless joined to enthusiasm and proselytism, can never injure others; every one should be left at liberty to think in this respect as he chooses. Let no one, however, consider that differing from others as to religion implies a difference in morality, or a neglect of moral principles; and let every gardener consider well what we have before said on this subject. (7762.)

7774. Physical education. It may be supposed superfluous to say anything to gardeners in respect to health. But the truth is, that since the general introduction of hot-houses, the profession of a gardener has become in some degree different from what it was; and he is now subject to heats and colds, which are liable to bring on inflammatory and rheumatic complaints. Being heated excessively in a hot-house, and cooled to a very low degree in the open air during winter, or in an ice-house (which is now in almost daily use in good gardens, for preserving fruits and vegetables) during summer, do not of themselves injure the constitution; but the evil arises from the partial operation of either extreme by which one part of the frame is cooled or heated sooner than another. By this the circulation and perspiration are unnaturally accelerated or diminished in these parts, and of course the action of the whole system deranged. When this takes place, the consequences are fever, costiveness, and often St. Anthony's fire, ague, rheumatism, &c. If taken in time, opening the bowels and the hot-air bath of the hot-house, taking care either to go at once from it to bed, or to the dry-stove and greenhouse, so as to cool gradually, will restore the system to order; if neglected, time, opening and sudatory medicines, and probably the doctor, will be required. The principal danger is to be dreaded from the excessive heat and perspiration produced by working in the bark-stove or in pits, such as during shifting, syringing, &c. To guard against these, the operator should limit his dress at the time to a loose flannel shirt and wooden shoes, and when finished, should wipe himself perfectly dry before putting on his ordinary clothing.

7775. The foundation of all health is regularity in the time and quantity of food taken, and in the common evacuations. If these are strictly attended to, everything will go well; if suffered to become irregular, everything will go wrong. The stomach is the primus mobile, as it were, of the constitution; the cause, when disordered, of the most afflicting diseases, and the first thing to be restored in order to their cure.

7776. A strict attention to personal propriety and sober habits need hardly be mentioned, with reference to young gardeners who mean to advance themselves; to suppose, indeed, that they would indulge in inebriety, or in alehouse society, is so entirely out of the question, that we shall not enter on the subject.

Sect. V. Of Economical Education, or the general Conduct and Economy of a Gardener's Life.

7777. A gardener, who has attained his twenty-fifth year, and has carefully employed the leisure time of the preceding ten years in improving himself, will now have formed his judgment on most subjects; and be able to determine a general plan for the future economy or management of his life. A man may be learned, or have a genius and taste in his profession, without having that taste or judgment as to the economy of life which leads to fitness and propriety of conduct, and will induce him to fix on an object to be acquired, and devise and pursue rational means of obtaining it. Bad taste in the common business of life may lead to bad plans, to a desire to acquire property too rapidly, to gambling, to match-making, to quackery, and, probably, even to crime and disgrace. The principal cause of this bad taste is, that what is called education is much too limited in its objects; or that part which is commonly left to parents or masters is but very imperfectly supplied. A youth ought not only to be instructed in the different laws by which the conduct both of individuals and society is regulated, but also in the art of forming a plan for the management of his talents, so as they may best contribute to his happiness. Nothing is more conducive to happiness, than fixing on an end to be gained, and then steadily pursuing its attainment.

7778. Forming a plan of conduct. Though some things in every man's life, and often the most important things, are the result of accident; yet here, as in every other case where a multitude of actions are to be performed with a view to an ultimate object, a plan must be of importance for their arrangement. No man is born in possession of the art of living, any more than of the art of gardening. The one requires to be studied as well as the other; and a man can no more expect permanent satisfaction from actions performed at random, than he can expect a good crop from seeds sown without due regard to soil and season. The greater part of mankind enter on life without any fixed
object in view; or, if they form some general notion of acquiring wealth or distinction, they form no plan by which it is to be accomplished; the consequence is, that such persons, after blundering on through their best years, arrive at the end without having gained anything but experience, now of no use to them. When we look round and observe the quantity of misery in the world; the greater proportion is, or seems to be, the result of a want of plan, or of a bad plan of life. How many parents are unsuccessful in their struggles to maintain a large family; the result of too early marriage, and a thoughtless and unmeasured procreation! How many find themselves arrived at old age, with no other resource for support but charity; the consequence of want of foresight in expen- diture! How many are suffering under poverty brought on by their own want of fru- gality, or positive extravagance; or under disease from excesses and irregularities committed in the hey-day of life! And how many, among those not born to inherit property, who, at no period of their life, have any other alternative between hard labor and deficient food, than disease and want!

7779. Want of plan may not, in every case, be the cause of all this misery; because accident enters into life for something, both in the unfavorable as well as the favorable side of the question; but we have no hesitation in asserting, that want of plan, as a cause of misery, is as ninety-nine to a hundred. Any plan at all, even a bad plan, is better than none; because those who set out on any plan will, in all probability, sooner discover its errors, if a bad one, and correct them, than those, who set out on no plan, will discover the want of one, and form a good plan. — Plan, in short, is predestination, as conduct is fate. The young gardener, who is just setting out in life, may well tremble at the consequences of proceeding on the journey without the guide of a judicious plan. This plan he must form himself: because he alone knows the quantity and rate of expenses; and these can be diverse. All that we can do is to give a few hints of what we think may be done, and tell all who are desirous of cultivating a garden, or anything else, how they may be saved from the ill consequences which will be the consequence of their want of plan.

7780. In order to be able to form a plan, it is previously necessary to determine the object to be obtained by it. Happiness is the object of every action of human life, and consists in the gratification of certain wants and desires; some of these desiderata are peculiar to youth, and others to old age; but many, as clothes, situation, rest, relaxation, amusement, &c. begin with the earliest, and continue to the latest period of life. All these gratifications are procured by labor; in savage life, by hunting, fishing, and gathering fruits, till the man, no longer able for these labors, is obliged to lie down and die of want; in civilized society they are also obtained by labor; but here, what is called property exists; and man, in the vigor of his days, when the supplies of his labor are greater than the demands of his wants, may, when he chooses not to gratify the latter to the full extent admitted by the former, can, as it were, embody a part of his labor to be made use of when he is no longer able to perform it with ease. A man, in this case, is said to arrive at independence; instead of want, as in the case of the savage; or of beggary, as in the case of the improvident.

7781. Independence is the grand object which not only a gardener, but every man destined to live by the exercise of his labor or talents, ought to have in view. At certain periods of life, when the imagination is vivid, and health and spirits in their utmost vigor, some may prefer glory, high literary or professional reputation, or even present pleasure; and it is a noble attribute of our nature to prefer these to mere accumulation of money: but a great warrior, poet, or painter, arrived at old age and want, if the latter be brought on by common improvidence, will not find himself surrounded by many marks of distinction; and, though it may possibly be some consolation to him, that the three or four letters composing his name will be sometimes pronounced together after he is dead, yet it will not be much.

7782. The exercise of his profession is the most rational mode in which a gardener, or any person properly educated to one, can pursue independence. Only extraordinary circumstances can justify a change of profession; in common cases it indicates a want of steadiness of character, or a want of success; and the latter is commonly attributed to want of skill. It is better, therefore, to pursue unremittingly the profession to which we have been educated, even though we should not be very successful in it, than to risk an infringement on character by adopting another. The practice of gardening, as we have already seen (7777.), is carried on by three different classes, serving, tradesmen, and artist gardeners. The greater number of young men cannot do better than commence in the first branch. To begin in the second, unless an established business is purchased, a partnership in a respectable firm procured, or some situation discovered where there is an effectual demand for produce, would, to a young man without connection, be attended with at least a loss of time, if not with greater losses. As to the third branch, the demand is so very limited, that it can never be recommended in a general way. It remains, therefore, for the gardener to look to the serving branch, as that by which he will the more certainly attain to independence.

7783. Of serving gardeners, there are two species, with their varieties; the public gardener and private gardener. The latter is the only species to be recommended in a general way; but whichever a young gardener adopts, it would be well if he could previously procure himself to be sent abroad for a year or longer, as gardener or collector to some expedition; or even if he could, at his own expense, visit Amsterdam, Antwerp, Leyden, and Paris. All this he may do at present, proceeding by sea to Rotterdam, either from London or Edinburgh, for less than twenty-five pounds; and a judicious young man, even though so much devoted to improvement as we suppose our young gardener to have been, ought to have saved that sum by his twenty-fifth year. In times of war it may be more expensive, or impossible.

7784. Situations. Though it be seldom that a gardener can choose a situation for him-
self; it may be proper to mention, that by far the best in the world are in England; there are some good situations in Scotland, and a few in Ireland; and there are occasionally good offers to go abroad as gardeners to the governors of British colonies, or to eminent merchants there. The principal foreign openings for British gardeners, however, are in Russia, where the emperor employs nearly a dozen head gardeners, generally British, and where the same, or a greater number, are in the service of the first-rate nobility. The salaries given are not very great; but the accommodations and necessary advantages are sufficient to admit a frugal man’s saving the greater part of the salary. Great care is requisite, however, to have a written arrangement before leaving this country, including a permission to return at pleasure, as no confidence can be placed in the verbal agreements of most of even the highest Russian nobility. We know of no other foreign situations worth notice. If a gardener thinks of going to America, or any of the colonies, on his own account, he will, of course, require a certain capital, and must also reckon on spending his days there. Supposing a young gardener to have obtained a tolerably good situation at home, and to have proved it for a year or two, he should, in our opinion, set about two things; the first is saving money, and the second is entering into the married state. The first is absolutely essential to the scheme of being independent in old age; the second nearly equally so to passing through life comfortably.

7785. With respect to saving money, we shall not attempt to state the proportion of neat wages that may be yearly saved; nor how the money may be best laid out; as these depend on circumstances. All we need suggest, is the necessity of keeping the ultimate object, and its great advantages, continually in view, and to prefer security of principal to high interest. As some data to enable the reader to estimate the accumulation of money saved, and put in a savings’ bank, or in the funds, we shall suppose a gardener to begin saving at the age of 27, and to continue saving till he attains his 50th year; laying out every year’s savings at only 4 per cent., adding half-yearly the interest to the principal; and at the end of that period purchasing an annuity for his own life, or the joint lives of himself and wife, with the accumulated sum: then —

7786. By commencing master-gardener, and beginning to save at twenty years of age, a gardener, or even a common laborer, may attain the same advantages as to independence; but with inferior domestic comforts, as he cannot afford to spend so much annually; and with less enjoyment from literary and intellectual sources, because his time for previous improvement is reduced one half; and in the after part of his life, as he will only be able to obtain inferior situations, he must calculate on laboring personally. If he begins at twenty, however, and saves till he is fifty, the additional time will bring his smaller sums to very nearly the same totals as those of the more accomplished gardener: thus —

7787. These calculations being made at the rate of 4 per cent. interest, and the Northampton valuation of life, (by which a man at 50 is estimated to live 18 years longer, while in London only 16 years,) must be considered as low rather than otherwise.

7788. The vulgar reason why a young man ought to save money is, that he may get together as much as may enable him to collect some furniture and get married. This, however, may be called saving to produce want and misery. A young loving couple, anxious to consummate their first wishes, will not be very nice in the quantity or quality of their furniture. All they consider necessary is accordingly often acquired before either are twenty. Housekeeping and propagation are commenced; and thus the foundation laid of a life of hard labor, scanty food, and their attendants, bad temper, and often disease. After twenty-five years of bustle and distraction, half a score of children have been produced, and are most probably growing up in rags and ignorance; and all that this couple can say is that they have struggled hard to create nine times as much misery as that by
which they are themselves oppressed. If the man had limited himself for twenty-five years to making the heads of pins, he might have accumulated as much as would have made him independent and comfortable, and still had sufficient time before him to marry, and enjoy the comfort and solace of a wife and children. But the use of a wife to a gardener, and to every man who is not independent, ought to be chiefly as the operative partner in his domestic establishment; to prepare his food, and keep in order his lodging and clothes. If, in addition to these duties, she has cultivated, or will cultivate her mind so as to become interesting as a companion, so much the better; and if the parties further think that they can attain their object of independence, and rear one or two children, let them do so. Universal sources of happiness should never be rejected, when they can be retained.
KALENDARIAL INDEX.

The almanac time in this calendar is calculated for the meridian of London; but as a kalendar of nature is given for the metropolitan district, the almanac time may, in every part of the empire, be varied to suit the local climate and vegetation.

In general, other circumstances being alike, four days may be allowed for every degree, or even 70 miles north or south of London: in spring, operations may be commenced earlier in that proportion southwards, and later northwards; but in autumn the reverse, and operations deferred as we advance southwards, and accelerated as we proceed to the north. In every case allowing a due weight to local circumstances.

**Remarks.**
A cold January is reckoned seasonable. The gardener, during this month, does not labor in the garden more than five hours a day; allowing one hour more for early and late attendance on hot-house fires, and seven hours for sleep, there remains eleven hours for personal improvement. Let the young gardener, who is ambitious of distinguishing himself from the old, and who is desirous of the respect and approbation of his profession, not let one of these hours run to waste, 7751.

*Insects, &c.* (2276) Destroy slugs, set traps for mice, and remove all larvae, webs, eggs, &c.

4. Hardy fruit department.

**Plant (5077).** Fruit-trees in general, in open weather.

**Protect (2906).** newly-planted trees from frost and drought by mulching (2908). fig-trees by fronds or mats, if you have neglected this business in October. (4562)

**Prune (2110).** apples, pears, plums, cherries, gooseberries, currants, and raspberries, preferring mild weather, or only moderate frosts. Prune first such trees as stand in compartments or borders that you wish to dig or dress (2579); apricots in the last fortnight, if very mild. (4558). Loosen the extremities of the shoots of such trees as it is not proper to prune at present, and wash them with soap-suds and sulphur, or scalding water if insects are suspected. (2576).

**Dig (1864).** and stir the earth round which have been pruned, trench ground intended for trees. (2438)

**Start (2438).** newly-planted trees. (2598)

**Clean trees from moss, mistletoe, &c.** (2624). Guard against hares, by tarring or lime-whitening their stems, or tying thorns round them. (2292).

**Destroy (2580).** insects by washes, or hot water, applied both to walls and trellises, and to the trees. (2296)

**Look** over the fruit in open boxes or shelves, and pick out decayed or tainted ones; but do not touch the casks of fruit in the cellar. (2299)

5. Culinary hot-house department.

**Glass case without heat.** (5386). Sow radishes, lettuce, carrots, small-salads (3392); and peas and beans for transplanting. (3639) 

**Hot-beds and pits.** (5378). Prepare for making up hot-beds for early cucumbers (3178) and melons (3281), if you have not begun in November. Sow early radishes, and small-salads on slight hot-beds. (4078) Sow carrot on a slight hot-bed, to produce a crop for drawing in April and May. (3460) Kidney-beans, peas, potatoes (3367. 3368. 3369), &c., may be sown and planted on slight hot-beds in small pots, to fit them for transplanting. (7446). Force asparagus (3349), sea-kale (3366.) and tart-rhubarb (3366,), on hot-beds, or in pits, or in the open garden. (3198, and 4531).

**Pinery.** (3597). Give air and water sparingly to pines; sow kidney-beans; take in strawberries. (2940. and 3605.)

6. Flower-garden. — Open ground department.

**Plant (5077).** dried roots of border-flowers, if not

In the first week: bees (Apis mellifica) come out of winter quarters; goats (Capra hircus) play at joints (Insecta) swarm under sunny hedgerows, and the earthworm (Lumbricus terrestris) lies out; hen-chaffinches (Fringilla coelebs) and the song-thrush (Turdus philomelos) sing; common lark (Alauda arvensis) sing.

Second week: the buntings (Emberiza alba) and linnets (Carduelis cannabina) appear in blocks; sheep (Ovis aries) drop their lambs; geese (Anas anser) begin to lay.

Third week: rooks (Corvus frugilegus) begin to pair, and resort to nest-trees; house-sparrows (Fringilla domesticus) chiph, and begin to build; the chaffinch (Fringilla coelebs) sings.

2. Kalender of vegetable nature round London.

In the first week: the snowdrop (Galanthus nivalis), witch (Ulex europaeus), white dead-nettle (Lamium album), polyanthus (Primula violets) flowers; and dandelion (Taraxacum officinale) begins to flower. Some roses and honeysuckles begin to expand their leaves.

Second week: common crowfoot (Ranunculus repens) dandelion (Taraxacum officinale) and the ferns with flowers of hazel (Corylus avellana) appear.

Third week: veronica agrestis in flower; many of the poplar and willow tribe show their catkins; and

Dress turf (6191.) and gravel (1927.) the former be done in moist, but the latter only in dry weather.

Form and repair lawns and turf verges, in mild weather. (2100. and 2101.)

Lay out (6875.) ground for a nursery, if not done in autumn; gather all manner of tree-seeds. (6892.) Dig (1854.) and trench (1870.) vacant ground borders, and plant trees, which are to stand a year or longer; fill up any vacancies as you go along. (747.)

Lift (3081.) plants fit for planting out. (2110.) nursery plants before planting: do this month, and keep the roots covered with matting or moss.

Gather (2392.) cones of the larch and other firs, and of the pine tribe. (6854.)

Protect (2136.) beds of germinating seeds with straw or litter; put other tender seedlings in pots under frames, or mats and hoops, from birds, mice, snails, and other vermin. (6857.)

Rotting-ground (6970.) turn over the different layers frequently, and see that none of them are soaked with water.

Seed-loft and cellar (6890.) look to all the sorts of seeds in these departments; whether buried in sand, or in heaps, layers, baskets, drawers, or bags.

Destroy (2296.) vermin, and, in bad weather, cut and saw off stems, and prepare parchment labels, number-sticks, hooks for laying, &c. (1517.)

Prepare (6817.) ground for grove or screen plantations; for useful strips; for detached, and for hedge-sides; and plant trees in general. (6878.)

Plant (2107.) in dry weather, deciduous trees, Scotch pine, and larch fir. (6997.)

Prune (2110.) deciduous trees, and also larch and Scotch pine groves (6892.), hedge-row trees, and indeed deciduous forest-trees in every form (6894.); cut and plash, repair and renovate, and complete hedges of deciduous plants or trees. (6917.)

Enclose and fence (6820.) ground intended to be planted (6892.) by posts and rails in all weathers (6823.); but by mortar walls, in mild weather only. (6853.)

Felt (6954.) timber-trees, where the bark is no object.

The (6905.) crowded plantations, distinguishing between such as consist of sorts fit for barking, or transplanting, and sorts for consumption in any of its forms of edgings, or coppices (6905. and 6915.), and otherwise prepare for planting the more extensive (6817.) sites. (6892. to 6851.)

Excrete and remove ground for forming pieces of water, &c. (1945. and 7217.)

Fourth week: the partridge (Tetrao perdicaris) begins to pair, the blackbird (Turdus merula) whistles, and the field and woodlarks (Alauda arvensis et arbores) sing; the hen (Phasianus colchicus) sits.
also the yew (Taxus baccata), elder (Alnus communis), the tulip (Tulipa), crown imperials (Fritillaria imperialis), and various other bulbs, boldly emerging from the ground.

Fourth week: the erica earnea, wood strawberry (Fragaria escula), some speedwells ( Veronica), the groundsel, and small snowdrops, and the stock and wallflowers (Erysimum), in flower. Some sorts of gooseberries, apricots, and peaches, beginning to open their buds.

Sow (3071.) radishes at twice or thrice (3760.), round-headed spinach twice (3771.), lettuce for successions; peas and beans in the beginning, and at the end of the month (3061. and 3061.); some early cabbages to replace any plants of the last August sowing: at the end of the month, red cabbage (3493.). In the last week sows aw (3519.), in the last fortnight dill, chervil, and fennel (4107. to 4109.), early Horn ear-rot near the end of the month (7161.), early Dutch turnips in the last fortnight (3828.), small salads every fortnight (4078.), onions for a full crop in the last week, and a few leeks at the same time (3816. and 3855.).

Temporary coverings. (2006.) Cover with litter, fronds of spruce and silver fir, mats, and other means, as circumstances may require.

Plant peas and beans, cucumbers and melons (3058.), chive’s, garlic, shallots (3828. to 3847.), horse-radish (4113.), horseradish (4145.), horseradish (4245.), and potatoes. (3493.) Propagate, by rooted offsets (1938.), and by seeds; mint, balm, sorrel, clover, bell, cinny, tarragon, fennel, and burnet. (4891. to 4815.)

Transplant. (3073.) for seed, if it was not done in cult, in the mission tribe, onions, turnips, turnips, beet, celery, endive, parsnips, and leek.

Dig (1864.) and trench (1570.) vacant ground in moderate weather, and perform all other operations of this kind only in dry weather.

Destroy insects by the usual means. (2260.) Store-room. Look over onions, and other dried roots. (704. and 1765.)

5. Hardy fruit department.

Plant (3071.) all sorts of fruit-trees, when the weather is fine (4361.) strawberries towards the end of the month. (4717.)

Protect roots of new-planted trees by mulching. (2850.) Potatoes, onion, garlic, and parsnips. (2850.) Trees coming into blossom. (2850.)

Prune (2110.) apricots, peaches, and nectarines, before the blossom-buds are much swelled (4140. to 4142.), and early in the month before the end of the month (4360. and 4403.), vines (2015.), and nail them, and also gooseberries, currents, and raspberries. (4670.) (4690.) (4690.)

Prepare ground for planting (3077.) spring-dress strawberry-plants; dig and dress ground where the trees are pruned, support newly planted trees with stakes (3095.), clear the bank of trees of moss, &c.; and, if necessary, the plants from which weeds, cattle, or hares may be expected. (2245.)

Destroy insects. (2260.)

6. Flower-garden. — Open ground department.

Sow (3071.) a hardy annuals in the last fortnight, if the weather be fine; most of the sorts are better deferred till the end of March. (3057.) Mint, horseradish and ten-weeks’ stocks, in a warm border, to be protected in severe weather. (2260. and 4686.)

Propagate and plant young plants from the root and herb; but September or March are better seasons. (4960.)

Plant shrubs and vines which are outside the forcing-houses and stoves which are at work. (3012. and 3031.)

7. Flower garden. — Hot-house department.

Glass case without heat. (2086.) Dress select auriculas, and cover them at night to promote their growth (3076.); sow ten-weeks’ stocks, and mignonette, for successional supply. (2618. and 4686.)

Hot-beds and pits. (2076.) In the last week, prepare for transplanting, continue to force and cover the usual sorts of border-flowers and Dutch roots in hot-beds and pits heated by fermentable substances, steams, or by coke-flues. (5013.)

Green-house. (2611.) Minimum heat for this month, 40 degrees, maximum, with fire-heat, 44 degree. Give air freely in fine weather, but water sparingly; the alternate drying by fire-heat, and then mace- dating by watering, is a sure way of killing tender plants in small pots.

Bori, or moist stone. (6214.) Give air as whenever the thermometer rises to 70 degree, or under. If the sun shines, keep up your fire and bottom heat. Begin to propagate by the usual modes; attend to the propagation of your stock.

Dry-stone. (6176.) Min. 45 degree, max. with fire-heat, 50 degree. Give water and air as in January.

8. Pleasure-ground and shrubbery.

Plant (3071.) deciduous trees and hedges, as in January; deciduous shrubs after the middle of the month. (6153. 6160. and 6180.)

Prune (2110.) as before, finishing most sorts by the middle of the month. (6142.)

Dig (1864.) as before, and include the flower and shrubbery borders towards the end of the month. Sweep and roll gravel-walks and lawns (6191.) trim the edges of beds with chisels, or coronet; remove mosses and weeds everywhere. (6201.)

Form and prepare lawns and gravel-walks, as directed for last month. (2010. and 2021.)

Fruit-trees. Sow kernels and fruit-stones (7011. and 7018.); lay quince, walnut, and mulberry trees; cuttings of the gooseberry, currant, and elder. Lay or graft the berberry, hazel-nut, and filbert. (7031.) Preserve cuttings of the vine and fig in dry earth, among plant suckers of the raspberry; prepare for grafting. (3043.)

Omnamental shrubs. Sow hardy deciduous sorts; lay and plant cuttings, and take off suckers for propagation; plant out in nursery rows, and prune deciduous kinds. (7051.)

Forest trees. (6892. to 7031.) Sow mountain ash, hornbeam, wild cherry, hawthorn, ash-keys, hazel-nut, acorns, walnuts, Spanish and horse chestnuts, &c.
KALENDARIAL INDEX.

holly and yew in the last fortnight. Plant cuttings of poplar, elder, and willow; lay in seedling larches; gather pine and larch cones. (6882.)

**Fork up** (1872.), dig (1854.), or trench (1870.), between November and the first half of December, for pruning bushes, open-tended trees, and evergreen trees, which are best pruned in summer, autumn, or late in spring.

Second and third timber and young trees, as for last month: remember not to touch bark-woods this month. (6043, and 6934.)

**Operate** (1862) on ground, with a view to forming rows of cabbages, and other effects of landscape-gardening. (7195.)

**MARCH.**

**In the first week:** the ring-dove (Columba palamata) coos, the white wagtail (Motacilla alba) sings, and the yellow wagtail (Motacilla flava) appears; the earthworm (Lumbricus terestris), and the snail (Helix), and slug (Lima), engender.

Second week: the jackdaw (Corvus monedula) begins to roost in churches; the tern (Parus carolinus) makes its spring note; brown wood-owls (Strix utulata) hoot; and the small tortoise-shell butterfly (Papilio urticae, L.) appears.

Third week: the marsh titmouse (Parus palustris) begins his notes; various flies (Musca) appear; the fox (Canis vulpus) snells rank; the turkey-cock (Meleagris gallopa) struts and gobbles.

Third week: the yellowhammer (Emberiza chitrinella) and green woodpecker (Picus viridis) sing; rooks, ravens (Corvus), and house-pigeons (Columba) build; the goldfinch (Carduelis carduelis) sings; field-cricket (Saracodes) open their holes; and the common flea (Pulex irritans) appears.

2. Kalender of vegetable nature round London.

**In the first week:** various species of the pine, larch, and fir tribes in full flower; the rosemary (Rosmarinus officinalis), the willow (Salix), and bay (Laurus nobilis), in blossom; various trees and shrubs in full bloom; and open buds.

Second week: the common honeysuckle (Lonicera periclymenum) and some roses in leaf; crocus vernalis, the other subspecies, and some scilla, in flower; pierwort (Ficaria) and creeping cowfoot (Ranunculus repens), hepatica and elder (Sambucus nigra), sometimes in leaf.

**March week:** the peach and nectarine, apricot, corchyrus japonicus, pyrus japonica, crown-imperial, saxifraga crisulida, buxus sempervirens, and other plants in warm situations in flower, or just advancing to that state.

Sow (1877) the main crops of most esculents. Drum-headed and Scotch cabbages for field-culture. (3492.) Pens (3501), beans (3516), lettuce (3570), spinach (3571), and small salads every fortnight. (4079) Indian cress (1141), a few savoy's (3519) for an early crop; and towards the end for a full crop. Onions (3816) for a full crop; and leeks (3535), some red and white cabbage (3492 and 3515), full crops of carrots (3718s) and parsnips. (3727.) Anparagus in the third week. (3582.) Cauliflower in the last fortnight, for a full crop (3585), for borecoles (3502), and Brussels sprouts for autumn and winter crops. (3524.) In the last fortnight, sea-kale (3920), cardoons (3533), turnips (3589) celery (4063), alexanders (3595), and most culinary aromatic, as parsley, dill, fennel, &c. (4691.) In the last week, summer savoys (3518), and mustard for seed. (4027.)

weather; ornamental deciduous sorts, not very tender, in fine weather.

Prune (2110) deciduous sorts, excepting such sorts as are apt to bleed, as the wild cherry, birch, and alder, when the buds begin to swell; and evergreen tribes, which are best pruned in summer, autumn, or late in spring.

This month and timber and young trees, as for last month; remember not to touch bark-woods this month. (6043, and 6934.)

Operate (1862) on ground, with a view to forming rows of cabbages, and other effects of landscape-gardening. (7195.)

**Plant** (3077), in the first fortnight, horse-radish (4114.), licorice (4245.), chives, shallots, and garlic, the herbs, and other esculents, as scallions or small bulbs for a full crop of large bulbs. Jerusalem artichokes and sea-kale, and in the last fortnight, potatoes for a full crop. (3676.)

Cropping of coverings (2506): continue these as last month.

Propagate edible perennialia by slips and offsets (2475), and from roots and bulbs.

Transplant the brassica tribe, lettuce, and asparagus. Fill up vacancies. (2286.)

Dig, &c. as in last month (1804), from composites and earths in heaps or hills. (1977 and 1981.)

Destroy insects. (2280.)

Store-room. Remove decaying articles, and admit plenty of air, &c. (1704. and 1765.)

4. Hardly fruit department.

**Plant** (3077) fruit-trees in general. The fig (3581) and peach (3582) in the last week of March may be planted in the garden. Planting gooseberry-trees before the middle of the month, and currants and raspberries by the end. (4042 4670. and 4935.) Alpine and wood strawberries may be planted, though autumn is preferable. (4177.)

Protect roots by mulching (3595.), and trees coming into blossom by the usual means. Prune to the middle of the month; but finish then if possible. If not, apricots may be pruned till the 4th (4532), peaches and nectarines till the 5th (4532), gooseberries till the 7th, red and white currants to the 10th or 12th, and the black currant to the 20th. (4648. and 4715.)

Dig and dress between rows of currant-trees, and where this operation has not been done before. Dress any strawberry beds you have not been able to do before. (4719.)

Fruit room. (3505)

Fruit-room. (3298.) Examine the fruit in the room; take care not to leave open the door of the cellar so as to raise its temperature above 40 degrees.

5. Culinary hot-house department.

Glass case without heat. Sow kidneybeans to receive a few weeks’ protection. Remove frames from the hot-beds. (3543.)

Hot-beds and pits. (3578.) Go on with hot-beds for cucumbers and melons. (3164.) Sow a few turnips on a gentle hot-bed to come in early. (3389.) Sow all sorts of culinary annuals. Give air and apply linings to maintain the proper temperatures. (1976.)

Attend to pine suckers and crowns; shift any that may require larger pots, and examine the roots of such as are sickly. (5718.)

Pinery. (3597.) Keep sowing kidneybeans, and filling spare corners with strawberry-pots for succession. See that your bark-pit be in proper heat, and attend to the temperature for this month, and the other points of culture. Pines are now generally shifted. (3218.)

Forcing department. (3240.) Attend to the culture of each particular kind; and generally to keep down insects by watering; promote setting of fruit by applying pots of steam to the house, and guard the nature of the house with vapors by powerful fires and waterings over the leaves and every part of the house.
6. Flower-garden.—Open ground department.

Sow (3071.) hardy annually (6507.), in the second, third, and last week; and some of the more robust half-hardy annuals about the end of the month. (6257.) Such seeds as flower the same year, as honesty, scabious, bastard rocket, sweet allison, clary, Chinese hollyhock, and Indian pink. (6005.) Biennials in general, and also perennials towards the end of the month. (6445.)

Propagate by rooted slips and offsets; but next month is preferable for rooting slips and cuttings. (2564.)

Plant dried roots: finish with the ammonoe and rumanculus in the first fortnight. (6526. and 6875.)

Transplant annuals from the patches in the border department, and biennials and perennials from the flower-garden nursery, into their final sites. (6110.)

Shelter choice border and all florists' flowers in severe weather. (2060.)

Hot-houses and pits. (6585.) In the first fortnight sow half-hardy annuals on a slight hot-bed for transplanting to come in first. (6513.)—Sow tender annuals at any period of the month. (6725.) Plant tuberoses in pots for forcing. (6023.) Force roses and other flowering or odoriferous shrubs and all desirable hardy flowers in pots. Sow seeds of green-house and hot-house plants to be propagated in this way. Plant cuttings for the same end. (2063.)

Green-house. (6211.) Make no fires unless the thermometer, in the open air, falls to 35 deg.; 45 deg. with fire-heat will be a good medium heat in this month. Begin to propagate by cuttings. (6027.)

Dead-stone. (6176.) A good medium heat for this month will be 55 deg., which may be kept up with very little fire-heat. Give water moderately, but see that what you do give wets the earth, and does not remain between the ball and the edge of the pot. Give air freely in fine weather.

Barb, or moist stone. (6214.) Give air in general, as in last month. If you wish to promote a vigorous growth, shift your plants into a rich compact water over the top about three o'clock, and then shut the house close up for the night. Do this only when the temperature has been up to 80 deg. (2005.)

8. Pleasure-ground and shrubbery.

Plant (3077.) deciduous trees and shrubs, also deciduous hedges; finish as early as possible, unless the season is unusually backward. Evergreens of the hardier sorts towards the end of the month. (641. and 665.)

Prune (2116.) deciduous trees and cut hedges, and finish this work as early as possible. In pruning plants, where the chief object is their flowers, attempt to preserve the shape of bearing these. In herbs, never begin to cut a tree before having a clear and distinct idea of what you wish to attain—is it health, shape, size, leaves, shoots, flowers, or roots? (3991.)

Dress orchard and apiary and shrubberies. Mulch, stake, water, and attend to neatness. (3295.) Dress and roll turf and gravel; attend to the margins with the flat-raser. (1357.)

Form and repair gravel-walks. In some situations imitation gravel-walks are required to be turned every two or three years and partially renewed. (1960.)

Fruit-trees. Sow kernels for stocks; lay the vine and the fig (4096. and 6845.); plant cuttings and eyes of the vine in pots.—Keep the young trees in a moist heat. Graft towards the middle of the month, or sooner or later, according to the season. Plant out seedlings in nursery rows. (7031.) Head down newly budded and grafted trees not intended to be removed. (3090.)

Ornamental trees and shrubs. Sow seeds of the hardier sorts towards the end of the month. Evergreens may be sown in the last week. Finish laying deciduous kinds, plant cuttings and suckers, and graft some rare sorts towards the end of the month. Plant out cuttings, layers, and suckers in nursery rows. (7031.)

Forest trees. (6892.) Sow nuts, keys, and berries, and also birch and alder seed. In the last fortnight begin to set out evergreen shrubs, &c. as in February. Plant out from the seed-bed or cutting-border in nursery lines. Dig between the rows of trees and shrubs not intended to be removed this month.

Weed, hoe, rake, and stir the surface in fine weather. Dig between nursery lines, where the plants as not to be removed. (6892. to 7033.)

Shelter and protect from cold, birds, and vermin. (2506. and 2280.)

10. Trees.—Permanent plantations and park-scenery.

Plant all sorts of deciduous trees and shrubs, the Scotch pine and larch firs. (6883.) Towards the end plant most sorts of evergreens. (6872.) Hedges of evergreens. Fill up blanks in plantations of two or more years' standing.

Head down trees intended to stote for underwood, or to produce single leaders for timber-trees or pales. (1039. and 6884.)

Tell and thin trees and cope; but the barking sorts not till the end of the month, when they will part with the bark. (6041.)

Sow broad-leaved woods; about the middle of the month is a good time, as the crows, rooks, and other vermin will be less likely to annoy the seeds, having the farmer's progeny to attack. (6829.)

Operations on ground, and masonry, may now go on with the utmost vigor; the days having attained a sufficient length, and the weather being generally dry; external brick walls for gardens, however, are better deferred till May, when all danger from frost will be over.

APRIL.

In the first week: the viper (Coluber berna) and whipsnake (Chelengis ascidia) appear; the mistletoe-thrush (Turdus nisivora) pairs; frogs (Rana) croak and spawn; and moths (Phalaena) appear.

Second week: the stone curlew (Charadrius aquaticus) clammers; young frogs (Rana temporalis) appear; the phessant (Phasianus) crows; the trout (Salmo trutta) rises; and spiders (Araneus) abound.

Third week: the crotched wren (Motacilla regalis) sings; the blackbird (Turdus merula); her, ra, rana (Corvus corax), pigeon (Columba domestica), hen (Phasianus gallus), and duck (Anas bosch) sit; various insects appear; and the filare (Turdus pilaris) is still here. Fourth week: the swallow (Hirundo rustica) returns; the nightingale (Motacilla luscinia) sings; the bittre (Ardea rutilia) makes a noise; the house-martin (Hirundo arctica) appears; the black-cap (Motacilla atropurpurea) whistles; and the common snipe (Co1uber nattire) appears.

REMARKS.

The weather of this month is distinguished by the rapidity of its changes. It is generally stormy, interspersed with gleams of sun. Sometimes, hail, ice, snow, and thunder, accompanied by violent storms of wind. Fruit-tree blossoms and half-hardy plants require protection and particular attention during this month. The young gardener, while at work, must multiply the generation and frituation of trees, and the gayety and delicacy of newly expanded foliage.
2. Kalendarial index

2. Kalendar of vegetable nature round London.

In the first week: the daffodil (Narcissus pseudonanus), the garden-daffodil (Hymenocallis orientalis), the wallflower (Cheiranthus cheiri), the cowslip (Primula officinalis), the periwinkle (Vinca), sloe (Prunus spinosa), and various other herbs and trees in flower.

Second week: the ground-ivy (Glecoma hederacea), gentianella (Gentiana acutiloba), pulmonaria virginigina, the auricula, liria sempervirens, cynoglossum omphalodes, and most of the common fruit-trees, and fruit-shrubs in flower.

Third week: some robinia, andromeda, kalmia, and delphiniums; a daphne mezereum, ulmus campestris, chrysopogon officinalis, mercia-ria perennis, and other plants, in flower.

Fourth week: the beechn (Fagus) and elm (Ulmus) in proper growth, and the berries of fruit-trees, the larch in leaf, and the tulip and some white narcissi and fritillaries in flower.

Sow seedcake for a full breadth; lettuce, small salads, and radishes, twice or thrice in the month. Peas and beans (301, and 3017), broccoli thistle (3556), boretta in the first week (5293), cabbages and savoys twice (2492, and 3316), spinach for succession (3711), turnips twice (3588), silver-skinned onions every week during succession (5003), onions, leeks, and cardoons, in the first week, for a general crop (2293), celery, in the first fortnight, for a general crop (3635), mustard for seed (5627), cabbage, in the second week, for a main crop (3571), kidneybeans, in the second week, for an early, and in the last week for a late crop (6354), asparagus and parsnips, in the first or second week, but not more (2571); red beet, in the third week, for a full crop, and also nasturtiums, salisyr, scorzonera and skirret (3540). Sow culinary aromatics and herbs also in the month.

Propagate by bulbs and dried roots. (1567) Finish planting the main crops of potatoes. (3576)

Propagate perennial culinary plants by slips and offsets, or in pots or half-hardy boxes. (3588)

Transplant lettuce, cabbages, seedcake, celery, and cauliflowers. (2575)

Dress artichoke and asparagus beds, or compartment (2025, and 3884). Hoe and thin the spaghetti, onions, turnips; ear up cauliflowers and cabbages, seedcake for blanching, peas, beans, and potatoes. Stick peas, tie up lettuces, destroy weeds, and stir the ground in fine weather. (2501)

Attend to insects, and to the store-room. (2280, and 6892)

4. Hardy fruit department.

Plant cherries, plums, apples, and pears, till the 10th; apricots and gooseberries till the 5th; peaches and nectarines, as early as possible, till the 1st; but not later than what you cannot accomplish by this period, unless the season is unusually backward. (2077)

Protect aet and pears. (2280)

Prune, if you have delayed it; but expect vines to bleed, and stone-fruits in general to be much injured by the operation, if not performed very early in the month, and even that is too late. In the last days of the month, rub off the buds of vines which appear where you do not wish shoots. (4553)

Rope and culture. Water, mulch, stake, and fence. Weed strawberry-beds, and pinch off runners, where you do not wish to have young plants. Decapitate fruit-trees, and especially those which will begin to appear on forward peach-trees; pick off caterpillars. (2280)

Frui-room. Turn, pick, wipe, and air the more choice, and pot-herbs; and look also to the baking apples and pears. (2589)

Frui-cellar. Attend to the temperature, and never break open a cask till you are in want of its contents. (2280)

5. Culinary hot-house department.

Glass-case without artificial heat. If the season is backward, sow in the first week kidneybeans, to be protected till the weather is mild. (2868)

Hot-beds. Continue preparing a succession of beds for digging and hilling out cucumbers and melons. Sow, transplant, shift, &c. all esculents, or pot-herbs, which are tender annuals, as gourd, basil, love-apple, capucium. Maintain the proper degrees of heat by linings. See to pine-suckers. Plant crowns and suckers taken off in the winter. (2512. to 2517.)

The soil of the hot-beds, for the purpose of the plants, reinforce the bottom heat, water and give air as judgment founded on experience, reflection, and observation, that the pot-herbs and other plants which are in the second or third week, will be the best for the hot-beds, and other articles grown or forced in the pinery, as vines, fruit-trees in pots, cucumbers, kidneybeans, and chard, &c.

Forcing department. All that it is proper, in our opinion, to say here, is "guard against supineness: there is much less danger from your ignorance than from your indulgence or want of vigilance." (2580)

6. Flower-garden. — Open ground department.

Sow annuals; all the sorts for a main crop, or for a session, if you have sown them in March (2077); half-hardy annuals in warm borders there to remain. (6131.) Biennials and perennials should be sown as early in the month as possible.

Propagate by rooted and unrooted slips and offsets. (3885)

Transplant all sorts from the nursery to the borders. (3078); tender and half-hardy annuals from the hot-beds. (3631.)

Routine culture. Weed, hoe, rake, stir the surface, remove all decayed leaves and stalks as soon as the same appear; hoe in succession, under the plants, or for an early and second stalk or two occasionally for seed. Never leave all the flower-stems for this purpose, and seldom all the pods or seed-vessels which are on a stem, as that would injure the plant.

Protect your auriculas from the extremes of every description of weather: if placed on a stage facing the north, or set on a shaded paved platform about three feet from the wall. (6833. and 6834.)

Destroy insects, and especially pick the grubs from the runner beans: if you attend to this, you will have no blow worth looking at. (2580).

7. Flower-garden. — Hot-house department.

Glass case without artificial heat. Alpines may now be entirely uncovered, and also prolonged annuals and most half-hardy sorts; a few half-hardy annuals will still be sown, if not done in proper season. (6131.)

Hot-beds and pits. Shift frequently such tender annuals as come to a height, and then turn them into more especially balsams. (6451.) Sow more seed, if you have not enough of plants; plant out some in the borders to grow strong broad plants, especially bachelor's buttons; if this be in very warm weather, plant the tufted roots, and shift those which are coming forward, if they appear to be stunted in their growth. (6324.) Attend to pots of cuttings, and seedlings from other of the following departments (6888.): —

Green-house. Fire-heat may generally be dispensed with in this month. Go on propagating by all the methods in your power; this is the fittest season of the year: a good deal depends on taking off, making, and putting in the cuttings, but nothing will answer, if constant attention is not paid to keep them warm, and shade them as to air, heat, and the ture afterwards. (6534.)

Dry-stone. No fire will here be necessary, excepting with your plant attention shall direct. The pine is a 40 deg. or 42 deg. Propagate by the usual means, which in general for succulents is cuttings; attend to bulbs now coming into flower. (6854. and 6858.)

Go on with twist stone. Go on, as in last month, shifting, propagating, and stimulating as the nature of the different hot-house plants requires, and as your views and duties indicate: not a waste of heat, or removal of dust, insects, &c. (6888. to 6716.)

8. Pleasure-ground and shrubbery.

Plant (3072.) such sorts of deciduous shrubs as you deemed too tender to plant last month; but finish this work in the first week. Plant a few roses as late as you can, in order to retard their coming into bloom; or, if you can afford the time and room, place potted roses in the ice-cold cellar in autumn, and do not take them out till the August following, by this means you will have a fine show in October.
November (565j. Evergreens, the hardest
sorts at the beginning, and the less so at the
end of the month. (567j)

Prune such deciduous shrubs as you have ne-
lected last month; evergreens from the middle to
the end of the month. (566j)

Plant and repair lawns, by procuring and laying
turf, and by sowing grass-seeds. Where it is de-
sired to destroy moss on extensive lawns, fold sheep
till moat is killed and burned by moisture and
mure; on small lawns, roll. In shady, damp situa-
tions, however, moss makes a better lawn than
grass, and it should be encouraged by forming the
surface of lawns of heath in all situations where
grasses do not thrive, as in towns, under close
trees, &c. Sow established lawns twice a month;
attend to gravel and margins. (561j)

Fruit-trees. (459j) Finish sowing kernels for
stocks, or new varieties. Plant cuttings of the vine,
fig, gooseberry, and currant, if it has been unavoid-
ably delayed till this unfavorable season. Craft the
pear, plum, and apple. (2015.) Attend to newly
grafted trees, and repair cracks in the clay, or renew
such cuts as may have dropped off; eradicate all
suckers, and pinch off shoots that protrude below
the ground.

Ornamental trees and shrubs. Finish sowing de-
ciduous sorts, as early as possible. Sow cedars, cy-
presses, and other ornamental evergreens about the
end of the month. Sow in pots or boxes, or in shady
borders of soft peat earth. Transplant evergreens,
(682j to 705j)

Forest trees. Finish sowing common tree-seeds,
and commence with the resinous tribe, the larches,
fiis, and pines; the cypresses, arbor-vites, &c.
Finish planting the deciduous trees in nursery rows,
as early as possible. (700j. Evergreens may be trans-
planted during the month. Kill-dry the cones of the cedar, if possible, by the fire, and get the seeds out in time to sowing the end of this month or beginning of next. (698j)

10. Trees.—Permanent plantations and
park-scenery.

Sow for forests and woods, and all sorts of pro-
fitable plantations. See the matter of last month.
Observe it is rather late for nuts, berries, and keys, but this is the proper season for small seeds. (701j)

Plant species, trees, shrubs, and shrubbery, such as
cedar of Lebanon, which may be cut and set up from
the nursery rows in the park, in March. (562j)

1. Calendar of animated nature round
London.

In the first week: the titlark (Alauda pratensis)
sings; the cuckoo (Cuculus canorus) is heard; the
gudgeon (Cyprinus gobio) spawns; the redstart
(Motacilla flamineus), swift ( Hirundo apus), white-
throat ( Motacilla alba), and stinging-fly (Conops
alatus) appear.

Second week: the turtle-dove (Colomba turtur)
coos; the red ant (Formica rubra), the laughing
wren ( Motacilla galeata), and the cabbage fly
(Musca vomitoria), the lady-cow (Coccinella
pepita), grasshopper-lark (Alauda locustae voce),
and willow-wren (Motacilla salicaria) appear.

Third week: the blue flesh-fly (Musca vomitoria,
vir) appears; black snails (Helix nigra) abound; and
the large bat appears.

Fours week: the great white cabbage-butterfly
(Papilio brassicae) and dragon-fly (Libellula 4-maculata)
appear; the glow-worm shines; and the fern
owl, or goat-sucker (Caprimulgus europaeus), re-
turns.

2. Calendar of vegetable nature round
London.

In the first week: geum urbanum, artemisia cam-
pa, salsola, and Stachys officinalis in the valley,
Convolvulus majalis, water-violet (Hottonia palustris), tulip-tree (Lilie-
dendron tulipifera), and numerous other plants, in
flower.

Second week: the oak, ash, sweet chestnut (Fagus
castanifera), hawthorn (Meipsils oxycanthus), the
common maple ( Acer campestre), horse-chestnut
(Rhus alpina), Polygala vulgaris, a perthade ( Atropa
belladonna), and various American shrubs, in flower,
and drye (Scaevola hyperborea) in ear.

Fourth week: oak, ashes, and beeches now ge-
nerally in leaf, and the mulberry (Morus nigra) be-
ginning to open its buds; the cinnamon-rose and
some other hardy roses in flower; and also the
ramble (Rubus fruticosus), moneywort (Lysimachia
campanulata), columbine (Aquilegia vulgaris), and
various other trees and shrubs, in blossom.

MAY.

REMARKS.

Vegetation now goes on with great vigor, though there are
often very cold and even heavy frosts, which materially
injure exotics, natives of the warmer climates, such as
the yew (Taxus baccata), and the camomile animal,
in common with most other indigenous to our cli-
mate, which only thrive at the highest spirts, and flowering
this month. Woe to the young gardener who exhausts his
spirts in any other way than in self-improvement.

Kitchen-Garden. —Culinary vegetables.

Some hardy aromatic herbs, if not done last month.
Small salads four times in the month for a complete
succession of successive and tender to the human
(370). Peas and beans once a-week. (3600). Spinage
once a fortnight. (3711). Carrots, for late drawing,
twice in a month. (3715). Borecole, in the first
week, for a second main crop. (3525). Dwarf kidney-
beans, in the first week, for a full crop in July; in
the last fortnight, for crops in August and Septem-
ber. (3533). Borecole and Brussels sprouts for the
last crop, and German greens to come in for spring
Savoy for the last crop. (3519). Onions for draw-
ing, young leeks to be late transplanted, cauliflower
in the second and third weeks for a Michaelmas
crop. (3542). The less hardy aromatic herbs, and
pumpkins, the last fortnight. (4276). Cucumbers for
picklers on a dry warm border, in the last week.

Protection. Continue this, nightly, for kidney-
beans and tender plants transplanted from hot-beds.
(3026)

Propagate by bulbs and dried roots. If abun-
donce of potatoes have not been planted, effect this
as early as possible; in late situations they may be
planted till the middle of June. (3575).

Plant slips and offsets.

Transplant the brassica tribe, lettuce, celery, rad-
ishes, and other plants for seed. (3971).

Routine: Transplant the brassica tribe, and all
other crops of beans, and also of peas; earth up cabbages, beans,
potato, &c. Thin, weed, hoe, and stir the surface
and soil with a broad fork, as often as the weather,
support stems, pinch off all dead leaves, &c.

4. Hardy fruit department.

Plant strawberries, if it has not been done last
month. (4717)

4 E
Prune what trees you have neglected, and run the risk of losing, or leave them unpruned till autumn as a proof of your prospect, and prune vines, peaches, and other early shooting trees against walls, and such gooseberries as are planted there to protect them from early frosts. Pick excepting selected ones of raspberries, and pinch off strawberry runners as directed for last month. (4717.)

Routine culture. Mulch, protect, and water where necessary, the late strawberry runners over the herbage, and especially after the fruit is set. (4717.)

Destroy insects, especially snails and caterpillars, on the first symptoms of the leaves rolling up, unroll them and pick out the grub before it does further mischief. Take special care it does not get at the petals of apple and pear blossoms. (2280.)

Prune late. Look over the fruit of every description; the increase of temperature which the increase of temperature will now cause to take rapidly. (2280.)

Fruit-cellars. Open a few casks of such dessert apples and pears as are now wanted for the table. Close them as soon as you have taken out the proper quantity, and let them still remain in the cellar. (2289, and 5299.)

5. Culinary hot-house department.

Glass case without artificial heat. Remove glasses from cauliflowers and kidneybeans, according to the need of the cases. Sow cabbage from under frames or hand-glasses in a warm border. (4571.)

Hot-beds. Go on with hot-beds for frames of melons after having drained the cucumbers under hand-glasses. (3992.) Sow cucumbers and melons for late crops, and attend to the various particulars in their culture. Attend to water, shade, shelter, &c. (3997.)

Pinery. Attend particularly to your fruiting plants, give abundance of heat and water, and keep down all manner of dirt, insects, &c. (2306.) Attend to mixing and pick out the grub before it does further mischief. Take special care it does not get at the petals of apple and pear blossoms. (2280.)

Forcing department. Produce the required temperatures, and attend to all the parts of good culture and neat management. (2301, and 2394.)

6. Flower-garden. — Open ground department.

Sow annuals of all sorts for succession. Biennials in the nursery compartment for a stock for next year. (6507. and 6513.)

Propagate, especially by cuttings from the stalks, as from the apple, &c. (5296.)

Take up bulbs and tuber roots, as crocus, hyacinth, lily, &c. (6501.)

Transplant, directed for the last month, stocks and herbaceous sorts in pots for winter. (3379.)

Protect tulip-beds and all rare florists' flowers from the midday sun, the rain, and the winds. (2306.)

Routine culture. Banks, edging, &c., and clear away dead leaves. Do not neglect whenever rain has rained the ground, to stir it up and refresh it as soon as it is nearly dry. Stir the surface round close patches of annuals, and refresh and top-dress all pots of prolonged annuals, now in full flower or in seed. Keep all the primula tribe rather dry at this season, and in the shade of a north wall. Plunge the pots in ashes or sawdust.

Destroy insects, and pick the grubs off roses. Detach seed-pods from all plants you do not wish to ripen. Water, top dress with judgment, and keep a vigilant eye to order and neatness. Shut yourself up in your room for two entire days, or go home from a similar time, and when you return look over the garden you will see many things that would have escaped you, had you gone on plodding day after day. Remember that such things happen but once in a while, and many of them may appear to you in good order, to another there may be much slovenliness and confusion. (7487. to 7493.)

Store-room. Lay up crocus and other bulbs and roots till wanted in the autumn.

7. Flower-garden. — Hot-house department.

Glass case without artificial heat. These will now be kept in full fruit, and transplanted annually in pots, for prolongation, and in striking from cuttings, &c. (5296.)

Hot-beds. (2305.) Go on as directed last month with your tender annuals. Plant a few tuberous for succession. Attend to cutting and transplanting from the hot-house and green-house departments. Shift and transplant as occasion requires. (2307.)

Grow-house. Give abundance of air every day, and in mild nights leave some all night; water over the top, and shut the house in the afternoon when you water. This invigorates growth wonderfully. Prune as before. Shift most of the plants, examine their roots.

Dry-stove. (6716.) Give abundance of air. Fires will not now be wanted. Look to bulbs, as soon as the risk of freezing danger. Shift and transplant as before, putting them into larger or smaller pots, according to their state, and your object.

Fruit-stoves. (6716.) Give abundance of heat, air, and water, if you wish the plants to grow and flower vigorously. (6688. to 6716.)

8. Pleasure-ground and shrubbery.

Plant deciduous trees and shrubs, but only to fill up a vacancy, or to cause a check for the purpose of late flowering. Immediately after performing the operations of pruning, shade, and water. (2268.)

House, especially the more tender sorts, but finish by the middle of the month. (6597.)

Plant evergreens, finishing by the middle of the month. (6597.)

Routine culture. Hoe, rake, weed, water, state, shade, shelter, &c. as circumstances require. Roll and wash gravel surface, if showers are frequent, but once a fortnight will do in dry weather.

Lay down turf, if not completed before, water well and roll immediately afterwards. (2201.)

Get gravel ready to be formed and repaired, but the work should have been completed last month. Roll well with a heavy roller. (1560. to 1568.)

Fruit-trees. (4501.) Look over grafted trees. Ornamental trees and shrubs. Sow the seeds of evergreen, or most American sorts, in the first and second weeks of the month. Lay and graft the tender sorts of evergreens and Americans. Plant out tender evergreens and Americans in nursery rows, and root the more convenient and quicker.

Forest trees. Finish planting out evergreens, seedlings, and nurseries as early as possible. Sow poplar and willow seeds at the first, and the remainder if not completed last month. These seeds will not come up if kept a very few days out of the ground. (7024.)

Protect from all sorts of garden enemies, and attend fully to neatness. (2306. and 2394.)

Planting evergreens may still go on, if the weather is dull and moist, but the sooner it is finished the better. (6707.)

Pruning. Sang recommends this as a good season for pruning old old, only because the wound heals quicker while the sap is flowing.

Fell oak woods and coppices, and other banking trees, but complete the operation about the middle of the month. (2301.)

Routine culture. Attend to planted ground under, or to be put under, light culinary crops. (7057.) Prepare ground for winter crops. Planting or forming of plantations by sowing, as the tree-seeds ripen. (6871.)

Operate on ground for water, or other territorial improvements. Continue to build and execute plans determined on at an earlier season.

**Remarks**

The weather is sometimes cold at the beginning, but is generally agreeable and steady towards the middle of the month. By observing the column indicating the greatest variation of the thermometer in each month, it will be seen that it varies, in London, only two degrees in June, which is less than in any of the preceding months. In July and August the variation is the same; but in March and October it is twice as much.

In the first week: the sedge-sparrow (Passer arundinaceus), the fly-catcher (Muscicapa striatula), the wisp (Faeda vulgaris), and several species of bee and butterfly.

Second week: the burnet-moth (Sphingis flippidula) and forest fly (Hippobosca equina) appear; bees begin to gather their stores.

Third week: several flies, butterflies, moths, beetles, and other insects appear.

Fourth week: insects abound; and singing-birds begin to return to the woods, and leave off singing.

2. Kalendar of vegetable nature round London.

In the first week: water-lilies (Nymphaea alba) and Tradescantia virginiana, amaranthus, cyclamen, solanum, and numerous other plants.

Second week: the vine, raspberry, and elder in full flower; and various bright roses (Rosa spinosissima), broom (Spartium), nettle (Urtica), and wheat in the ear.

Third week: the orchis, epilobium, iris xiphium and xiphoides, the hardy ivy and gladioli, and a great variety of garden and field plants in flower; also the wheat and many of the pasture grasses.

Fourth week: some black and red currants ripe; strawberries in abundance; young shoots of trees and shrubs have nearly attained their length; oats and barley flower; blueberry flowers, yellow elders, (Centauraea cyanus), and numerous others, in bloom.

Sow peas and beans once a week or ten days. (3601.) Cucumbers for pickles. (4678.) Gardens in the first week. (4211.) Small salads and lettuce every week. (3771.) Tomatoes in full bloom and sprouting in the first week. (5717.) Kidneybeans every fortnight, for succession. (3833.) Endive about the 10th or 24th, for the main autumn and winter crops. (3833.) Carrots twice in the month for summer use, also purslane. (4089.) Cabbages, of quick-growing sorts, for summer and autumn consumption, about the beginning and middle of the month. (3492.) Turnips in the first week, for succession; and in the second and third week for a full autumn crop. (2683.) Carrots (3717.) twice, for drawing young. (6507.) Broccoli and borecole, in small portions, for succession, late in spring. (3255 and 3597.) Onions to be drawn young.

To save seed. Mark out cauliflower plants, lettuce, &c., and let them send up their flower-stems. (3552.) Protect when and where necessary. (2306.) Propagate by bulbs, roots, offsets, slips in showery weather. (1887.)

Transplant (3793.) the brassica tribe, cardoons, endive, lettuce, and other plants and herbs, also plants reared in hot-heds.

Root culture. Tie up garlic and ramuncle leaves in knots to check the progress of the flower-stalk. Stick and top peas; top beans; earth up foxhioo to blanch; also white beet. Thin, hoe, weed, and stir the ground as before. Support with stakes, and water as far as practicable; in dry weather.

Transplanting carys. (2300.) Cut and dry herbs for winter use. Gather ripe seed. Discontinue cutting asparagus at the end of the month.

4. Hardy fruit department.

Prune and train the summer shoots of all descriptions of wall and trellis trees. (2110.)

The summer shoots of fruit-shrubs, and of all fruit-trees, excepting high standards, which do not require this nicety. (2576.)

Routine culture. Mulch, water, fasten by stakes, weed, and thin, and stir the ground as before. Support with stakes, and water as far as practicable; in dry weather.

Destroy insects. Strew sulphur over the mildew, water for the acaria; direct a stream of tobacco smoke against the aphids and thrips, burn the tips of the leaves and stems. Wrap over cherry-trees and protect the fruit from the birds. Water strawberry plots every day in dry weather, desisting a little as the fruit begins to ripen.

5. Culinary hot-house department.

Glass case without artificial heat. Raise hand-glasses over cucumbers on props, and train out the runners, in the second or third week. Ridge out melons in good earth, in the last fortnight, and cover with mats till the end of the third week. (3328, and 3329.)

Hot-beds. Keep up adequate temperatures for ripening the fruits by linings. Reinforce melon ridges with linings. Train, prune, and impregnate as circumstances require. Attend to air, water, shade, and ventilation. Keep up proper linings to your beds of pines.

Pinery. Attend to what was stated last month. If you want extraordinary large fruit, and do not mind losing the suckers, apply the usual means, viz. heat, water, and removal of all stem and root suckers; also the use of tongs.

Forcing department. See last month. Keep up successive supplies of kidnebeans, strawberry, and fruit-trees in pots. (3338.)

6. Flower-garden. Open ground department.

Sow a few hardy and half-hardy annuals for succession, as before. (6507, and 6535.) Prepare the cuttings, if plants are as proper for this purpose, as they go out of flower. Pipe and lay pinks and carnations towards the end of the month, (3717.) and transplant. (4139.)

Take up bulbs and other tuberous roots, dry them in the shade and remove them to boxes or drawers in the store-room, wrap the finer sorts in paper. (6901.)

Transplant (3079.) annuals in the borders and in pots for autumn and winter flowering. Biennials and perennials may also be transplanted into nursery rows this season, or even where they are finally to remain.

Routine culture. Mow, weed, hoe, rake, thin, stir, and draw to, and keep up an appearance of polish and high keeping as your strength of men and other means will permit. (6191 to 6301.) Shade, shelter, water, and attend to carnations (3689.) and other flowers, as well as the greens and all manner of insects. (2350.) Go round the garden frequently and examine everything minutely, and reflect on what might be done to promote its growth and beauty. To aid you, imagine it to be a garden which you were sent to criticise, and to be paid according to the number of faults you found, and imagine you to be the gardener of the garden of some one you hate. (7438, and 7439.)

Glass case without artificial heat. Propagate the dianthus tribe by pipings under hand-glasses and frames. (6406.)

Hot-beds and pots. Put pots of carnations and pink pipings in gentle heat, it will facilitate their striking. (6406, and 6460.) Do not forget to give head-room to your balsam and other tender annuals, which should now be noble-looking plants. Attend to pots of cuttings and seedlings; also to young stove plants put into this department for more rapid advancement.

Green-house. As soon as the mulberry comes into leaf remove the plants to a fit situation in the open air. Some plunge them in ashes; but the major part set them on scoria, gravel, or pavement, in a particular heated situation; in cold weather a certain degree of shade are essential to their well-doing. (6535.)

Dry-stores. (6175.) Give abundance of air night and day, but be moderate as to water. Cease to water bulbs soon after they have done flowering; let them go slowly into a state of hybernation, and then take them off and set them in dry stores.

Bark, or moist stone. Increase your heat with the lengthening day, and prolonged sun, and by consequence increase the concurring agents of vegetation. Propagate by the usual means; save seeds where you can; destroy insects; and attend to neatness. (6688, to 6703.)

8. Pleasure-ground and shrubbery.

Prune and regulate summer shoots, and take off suckers where not wanted to extend the bush or propagate the species. (6010.)
Routine culture. Weed, hoe, rake, stir the surface, support climbers, regulate the shoots of creepers, &c. Water and roll any new-laid gravel to combine it properly with the rest. Dress, roll, and mow lawns and turf in every form. Keep your eyes open to every part of the ground, for this season; for now perfect neatness and the utmost polish and high keeping is expected. Do not trust to what you are told to do in calendars, but think for yourself, and exert the frequency of those more machines of gardeners; for though man is a thinking animal, yet he is also a lazy imitative animal, and will do exactly in any way, and not even think, unless urged on by some strong motive. All your faults will be discovered, sooner or later, and rely on it you will receive a proportionate disgrace from your neighbors or visitors; if you are attentive to your duty your merits will be discovered in like manner, and you will receive appropriate credit and reputation, which is your capital stock in trade, on which you depend for your livelihood. (2372.)

Fruit-trees. Begin budding during the last fortnight. Look over all your newly grated and all other trees; rub off superfluous, irregular, or ill-placed shoots and suckers, and tie weak grafts and dangling shoots from budding stocks to neat stakes. (3039.)

Ornamental trees and shrubs. Lay the summer shoots of roses, hard-wooded evergreens, and other sorts which are proper to be propagated in this manner. Put in cuttings of young wood properly pruned over winter, best in the last fortnight. (2353.)

Forest trees. Collect and sow elm-seed in the third or fourth week; or if you do not wish to sow it, lay it in the store-loft. (7062.) Seedlings of the more choice pines may be thinned where too thick, and the thinnings planted and shaded about the end of the month. (6997.) Gather Scotch elm-seed from the middle to the end of the month, (7293.) Attend to kitchen crops among transplanted trees, and in vacant places in general. (7067.)

Fell oak-coypies, if it has not been done before. The middle of this month will prove a better time, as to the trees, than the middle of May, as they will not bleed so much: but the bark will not peel so well. (6991. to 6997.)

Prune and thin the side shoots of the present season, from established trees. (6884.)

Routine culture. Stake newly planted tall hedge-row trees, where not done before. Attend to weeds everywhere, and to ground under-crop. Prepare ground for autumn sowing or planting.

Gradually work on ground and buildings are carried on at this season, with this advantage that in the three preceding months. The ground is hard and difficult to penetrate; and the moisture in new-built masonry dries too rapidly.

JULY.

Remarks. This was called hay month by the Seasons, and in it are more pigs, cattle, and sheep than during any other. The young gardener should now devote a considerable portion of his time to the drying and storing of vegetables, roots, and triplicates, in order to acquire a stock to exchange with brother-gardeners or naturalists; or with book-sellers, apothecaries, plumbers, and dyers, for the loan of books, and for aid and instruction in study.

In the first week: the cuckoo (Cuculus canorus) leaves off singing; the stone-curlow (Cheiradris edentecmensis) whistles occasionally late at night; and the golden-crested wren (Motacilla regulus) now and then chirps. Second week: the quail (Tetrao peruvigineus) calls; the cuckoo-slit, or frog-hopper (Cicada spumaria), abounds.

Third week: young frogs migrate; hens moult. Fourth week: the horse-fly (Tabanus bovinus) appears; and partridges fly.

2. Kalendar of vegetable nature round London.

In the first week: encluther's nightshade (Cicura lactea) blossoms; Linum sinuatum, in flower, and pinks and carnations in full bloom. Second week: the fallen star (Tremella mucedo) appears, also piaff-balls (Lagarospermum bovista), and sometimes the common musroom (Agaricus campestris).

Third week: raspberries and gooseberries ripen, potatoes in flower, asparagus in berry, the liliums in flower; and the kindling of the fire, which we have seen latterly, is a subject in which every one now engages.

Fourth week: the truffle (Tuber cibarium) now hunts or dug up in commons and forests; nightshade (Solanum nigrum), devil's bit (Scabiosa succisa), burnet (Sanguinaria canadensis), Primula sessiliflora, and a great number of plants in flower.

Sow (3071.) salads and lettuce in shady situations, for successful crops. Turnip-radish for an autumn crop. (5700.) Kidneybeans, in the first week, for a late full crop. (3563.) Peas and beans, in the first week. Broccoli, before the 10th; for a late spring crop. (5577.) Endive, in the first week, to come in at the close of autumn; in the third week, for a winter crop. (2681.) Broccolo, before the 10th; for a late spring crop. (5577.) Finochio, for succession, in the first fortnight. (4099.) Round-leaved spinach, in the first week, in a shady border for a second sowing. (7371.) Triangular-leaved, or prickly spinach, in the last week, in poor ground to stand the winter. (7375.) York and sugar-loaf cab-

bages, in the first week, for autumn use, and in the last week, for winter and spring. (3495.) Carrots, in the first week, in a shady border. (3718.) Turnips twice or thrice, in showery weather. (3698.) Welsh onions, for autumn, and in seed, must be sown in the last week to stand the winter. (3816.) Coriander and borage for young crops. (4022. and 4127.) To save seed. Mark out the brassica tribe, and other seedlings in perfection, and let them shoot up flower-stems.

Propagate by slips, offsets, &c. where not done before, and where plants have completed their form; to be cut down as tarragon, and other pot-herbs. (4063.)

Transplant (7059.) as before, and include celeriac and celerin, endive, &c.

Routine culture Stick and top peas and kidney-beans, top common beans, train cucumbers and gourds, earth up the leguminous crops and potatoes, and thin the surface wherever necessary, among all descriptions of crops; water, as far as your time will permit, and particular crops require.

Taking crops. (2969.) Take up shallots, and dry them for winter use; also romacole and garlic when ready. Gather ripe seed and onions, and cut herb-beds thin to dry, drying and storing with the fruit of young gourds for pies, stews, and pickling.

Destroy insects, and ward off vermin. (2570.)

4. Hardy fruit department.

Plant strawberries in the open garden; and in pots for next winter's forcing. (4717.)

Potatoes thin, and regulate all the summer shoots of wall and espalier trees, and dwarf and tall standards. (2873.)

Routine culture. Hoe and weed fruit-tree borders. Potatoes, decorative, under winter enclosure when necessary. Water alpine strawberries, which will now be in full bearing, every third or fourth day, unless in a very droughty season. (2577.)

Destroy (2575.) insects; keep earwigs, ants, boys, and idle women from fruits, as cherries, &c. approaching to a state of ripeness.

Preparation. (2618.) This will now be empy; clean and wash every part of it, and air it well for occasional summer and next winter's use.
1. Calendar of animated nature round London.

In the first week: flying ants (Fornices) appear; bees kill their drones; and the swallow-tailed butterfly (Papilio machaon) appears.

Second week: young martins (Hirundo rustica) and swallows (Hirundo rustica) begin to congregate, and swifts (Hirundo apus) depart; the whame, or burrel-fly (Estrus bovis), lays eggs on horses.

2. Fruit-cellars. (2299.) If you have attended properly to casking up keeping-apples and pears, you will still have a supply, and even of grapes in some cases. If the cellar gets too warm, the casks should be removed to the ice-house.

3. Culinary hot-house department.

Glass case without artificial heat. Plant out melons and cucumbers shading and watering, &c. (3164, and 3271.)

Hot-bed and pits. Prune melons and cucumbers; give air and water, and attend to shading and watering; collect mushroom-spawn; attend to young pines. (3718.)

Firberry. You will now begin to cut fruit in abundance. See to the stools: earth them up, so as to cause the suckers to strike root: put them in a warm house or root-room, and give proper supplies of water. You will thus gain much time, and profit from the expiring strength of the parent plant as long as possible. This is the true way to fructify and ripen melons.

Take up bulbs as they go out of flower: this work should generally be completed by the end of the first week, unless for the lily tribe, the colchicum, and a few others.

Transplant late sowings of annuals, and also biennials and perennials, into nursery rows. (3079.)

Routine culture. Eradicate all weeds the moment they appear; keep the surface always fresh, and rather rough, never smooth and battered. It is better to have little clods and knots of earth than to have a naked or dug surface as smooth as a table. The clods and knots make variety of light and shade, and are besides more favorable for the admission of air, heat, and water to the roots. Shade, shoot, and stratify the gathered seeds as they ripen, and dry them in the seed-room or lofts, the windows being open. Destroy insects; cut out broken stalks, and diseased parts of plants. Cut down sedge which have done flowering, and remove all decayed leaves.

Gather flowers neatly with a knife, and so as not to disfigure the plant. (6196.) Gather in general from the reserve-garden, so as not to disfigure the borders.

Store-room. (1704.) Look over your bulbs now and then; they should not be mouldy. See also to your newly put-up seeds. (1705.)

4. Flower-garden. — Hot-house department.

Glass case without artificial heat. (9868.) Most of these, at this season, are given up to the kitchen-garden, or used to protect at nights the tender annuals, some of which, as the humble and sensitive plant, cannot so well be put out in the borders. (6724, and 6725.)

Hot-beds and cold-pits. (3078.) Little use is now made of them by the florist, unless for propagation of stove plants. Attend to cuttings from whatever department. If you are endeavoring to flower the more delicate aquatics, see to the keeping up a regular heat.

Green-house. (8211.) This will now be filled with pots of tender annuals, which only require shifting now and then to a certain height of growth; and then only common routine culture.

Dry-stone. (6176.) Some set out a part of the succulent tribe this season. If you do, let it be in a very warm situation: heavy and continued rains prove very injurious to succulents in the open air.

Bark, or moist-stone. (6214.) Increase the temperatures, and the increase of light, and add air and water accordingly. Attend to all the minor points of culture. See that the floors or paths of your stoves are swept every day, and wash your plants well whenever: keep all bunches of flowers at all times unsightly. Be sure to dash this water on all plants in blossom, in order to curtail their beauty, and lest they should set fruit.

6. Pleasure-ground and shrubbery.

Prune (2110.) as in last month: box-edgings and evergreen hedges in the last week of this month, if the season is a forward one. (6190.)

Routine culture as in June.

Lawns. (6191, and 6097.) Attend to these, according as the weather may be favorable. Keep the mowing and reseeding in good order. If in dry weather, set your men to mowing at three o'clock, and let them rest from eleven till three o'clock: in moist weather the time of day is of less consequence. In France and Italy, the working gardeners, during summer, may be said to do the principal part of their work early in the morning, and late in the evening.

Gravel-walks. Weed and roll these in moist weather. When dry, and the gravel becomes loose, water and roll. (1957.)

Fruit-trees. Attend to budding, and look over your grafted trees; pinch off all obtruding shoots and suckers. (6029.)

Ornamental trees and shrubs. Continue laying summer shoots, and plant cuttings and bud as in last month.

Forest trees. Sow elm-seed; attend to weeding and cleaning all beds and rows of seedlings, or other nurseries, and of transplanted trees. (7083.)

Prune (2110.) evergreens in the last week, if the summer has been so favorable as nearly to ripen the wood.

Routine culture. Attend to kitchen, or field crops, among young plantations; and to large weeds everywhere. Do not forget hedges and other fences: keep all lots of flowers at all times in repair. (6830.) Few operations in landscape-gardening can now be commenced; but some, as excavating for water, &c. may go on.

Remarks.

This is the hottest month of the summer; many seeds of herbaceous vegetables ripen in this month, and most sorts of culinary crops, raised in the open garden, are now in perfection. Insects, especially the winged tribes, now abound; and the young gardener should be assiduous in collecting them for the same object as he collects specimens of plants. By carrying a small box in his pocket, he may pick them up while at work.

Third week: the black-eyed marble-butterfly (Papilio semele) appears; various birds reassume their spring notes.

Fourth week: the nuthatch (Sitta europaea) chatters; the stone-curlie (Charadrius albicollis) whistles at night; the grasshopper (Caprimulgus europaeus) and young of (Sitta uulca) make a noise in the evening; robin-redbreast (MOTINulus rubecola) sings; and rooks roost on their nest trees.

4 E 3
2. Kalenderial vegetable nature round London.

In the first week: meliot (Trifolium officinale), rue (Ruta graveolens), yellow succory (Pieris hieracioides), and burdock (Arctium lappa), in flower; the latter makes a good decorative article.

Second week: wild clary (Salvia verbenacea), meadow-rue (Thalictrum flavum), ploughman’s spikenard (Conyza squarrosa), and various other natives, in flower.

Third week: the mallow (Malva), lavatera, holly-hock (Alcea rosea), and lobelias, among the garden-flowers, and corn-yew and potamogetons among the wild plants, now in blossom.

Fourth week: the autumnal crocus (Crocicum autunnum), aster, solidago, senecio paludosus, teasel (Dipsacus fullonum), and various other plants, in flower; the earlier varieties of all the hardy kernel-fruits ripe.

Sow (3071) turnip for a main crop, in the first week; but sowings made after the 15th seldom fully succeed (4308); make frequent sowings of endive, turnip, radishes, and lettuce (5701); the latter for autumn and winter crops. Parsley may now be sown for winter and spring use, this being the most natural season for sowing biennials. (4292). Sow the green-sea-cabbage for large salads for the first week, to come in in the autumn of the following year and subsequent winter; and early sorts in the first week of August. Spinach, in the first or second week, for a main winter crop. (5715.) Carrots in the first and third weeks for drawing young in spring. (5718.) Endive and ceps (201) in a packet; chervil for a late crop; onions for a full winter crop; angelica, fenel, succory-grass, and blessed-thistle for next year. Cauliflowers twice, in the third and fourth week, for cut over the winter, in sheltered borders, or under frames. American cress, in the last fortnight, for a spring crop.

Sow (5718) artichokes (1897) by slips and cuttings, where necessary.

Transplant (3709) as in last month, and include leeks, perennial herbs, &c.

Routine culture. Displace the suckers from such artichoke heads as you would grow to the greatest magnitude; stick peas and runner kidney-beans; earth up the brassica and leguminous tribe, and pot them up to ripen, if necessary. Keep the long-stalked white beet, finocchio, &c. for blanching. Hoe, thin, weed, stir the surface, water, shade, and attend to necessary order; and clear off all crops the moment they are done with. (2367.)

Taking crops. (2392.) Take up the allaceous tribes as before; gather pickling cucumbers; cut herbs; gather ripe berries.

Destroy insects. (2375.)

4. Hardy fruit department.

Plant (3077) strawberries, as directed for last month.

Prune (2573) regulate, train, and otherwise arrange the summer shoots of all fruit-trees as directed for last month.

Routine culture. Hoe, rake, weed, and stir the surface under gooseberry compartments, and in general under and around all fruit-trees. Where fruit is beginning to ripen, be very moderate in thinning the leaves. Mat up small fruits on north walls, intended to be preserved till late in autumn; water spring planted small trees in dry weather, also strawberry-plants in blossom and fruit. Dress strawberry-beds that have done bearing. (4726) and (4727.)

Take (2258) gooseberries and currants, with the fruit, from the top of the stem, about 4 inches below the terminal bud, to April, and such wall-fruits as is ripe with the fruit-gatherer. (See figs. 141. to 152.)

Destroy (2576) insects; the acarus will now be your greatest enemy.

5. Culinary hot-house department.

Glass case without artificial heat. Sow long prickly cucumbers for a late crop, to receive the aid of artificial heat in October and November. Sow in pots, or make layers or cuttings for the same purpose. (5185.)

Hot-huts and pots. (3076.) Recruit the linings of melon-beds, and prune, train, weed, water, and impregnate all the cucumis tribe.

Mushrooms. Search for spawn, in cow pastures more especially, and take care of it when hot. (4364.)

Piney. See last month.

Forcing-houses. (3998.) Most of the forced peaches will now be gathered; fully expose the trees, unless you have an area of protected grapes under the rafters, or running along the top of your trellis, as to render it worth while to keep the sashes on to ripen them. If a house were better, or have them together in such containing proportions. Cherry-trees and others in pots, and of which the shows are ripe, should be put in a state of hygiene, in a place to which they may be exposed to the cold, to form a cold or shaded border. This will fit them better for a succeeding early artificial spring.

6. Flower-garden. — Open ground department.

Sow (6346) auricula and other primula seeds in pots and boxes, as so as to admit of winter protection. These seeds come up stronger now than if kept till the following spring; and, though they will not flower sooner than the second spring after sowing, yet they will then flower much stronger than plants sown in the autumn. (4149.) Mignonette, stocks, and other annuals in pots, for prolongation through the winter. (6486.)

Propagate (1587) by all the usual means. This is the best time for taking off old rooted slips of the auricula: the Lancashire florists will never touch these till the third day of this month, when their florists' sales commence. (6308.) and take the heart out of the few plants which had not ripened their stalks before, as of the margot and red and white lily. Plant (6693) some sorts of biennials and perennials, and your latest sowings of annuals and half-hardy annuals intended for the borders.

Routine culture. Prepare composts. Hoe, dig, rake, and weed, and stir, shade, show, sweetpeas, and other climbers. Water, and gather seeds; sow verges and glades where they exist in the flower-garden, according as you find they require it.

Store-room. (1704.) Look once a-month at your roots and seeds; and gather, dry, clean, and store up seeds as they ripen, attending to name and date each packet or bag accurately.

Glass case without artificial heat. See last month.

Hot-huts. (6778.) Attend to such cuttings as are forming in these, and to late crops of tender annuals. Prepare successive of tender annuals for the green-house.

Green-house. (6211.) Attend to your tender annuals; and do not forget creepers, and vines, and such plants as being planted in the ground cannot be turned out. (6474) to 651.

Dry-stone. (6176.) About the end of the month, it will be safe to replace such plants as you had ventured in the open air. Any you put in cold-pits, may remain a month longer. (6503, to 6508.)

Dry-stone. (6214.) See last month. Attend to creepers, climbers, and vines, also aquatics, which, if you have a proper aquarium, will now be in great perfection, and highly beautiful. (6190.)

8. Pleasure-ground and shrubbery.

Plant (2077) evergreens towards the end of the month, as larch, and shade, for some days, if very delicate sorts. (2008.)

Prune evergreens (2110); roses for forcing. (6559. and 6560.)

Routine culture. Hoe, rake, weed, &c. as before. Prepare ground for planting; dress gravel and grass as in June and July.

Prune rock gardens, lawns, by turfing or sowing. It is now an excellent season for sowing lawns. See that you make use of the proper grasses, according to the soil and situation. Attend to gravel walks. (1567.)

Frut-tree. (3029.) Finding budding of the late va-

In the first week: young broods of goldfinches (Fringilla carduelis) appear; the linnet (Fringilla montana) congregates; the bull (Bos taurus) makes its shrill autumnal noise; and swallows (Hirundo rustica) depart.

Second week: common owls (Strix flammea) hoot; the saffron-butterfly (Papilio hylas) and willow red under-wing moth (Phalaena picta) appear; hawthorns (Crataegus monogyna) are now cheap.

Third week: the ring-ouzel (Turdus torquatus) appears; the flycatcher (Muscicapa atricapilla) withdraws.

Fourth week: the star (Sturnus vulgaris) congregates; the wood-lark (Alauda arvensis) sings; the woodcock (Scolopax rusticola) and fieldfare (Turdus pilaris) appear; and the swallow (Hirundo rusticola) departs.

2. Calendar of vegetable nature round London.

In the first week: the fungus balanus albus appears; traveller’s joy (Clematis alba) and parnassia palustris in flower.

Second week: catkins of the hazel and birch form, dangling boughs, and green, red, and black berries are found on the bramble at the same time; leaves of the sycamore, birch, lime, mountain-ash, and elm begin to change.

Third week: the ivy (Hedera helix), laurel (Prunus laurocerasus), and furze (Ulex europaeus) in flower.

Fourth week: hips, haws, and nuts ripe; leaves of plane-tree (Platanus) tawny; of the hazel, yellow; of the oak, yellowish green; of the sycamore, dirty brown; of the maple, pale yellow; of the ash, the leaves are changing; of the elm, orange; of the hawthorn, tawny yellow; of the cherry, red; of the hornbeam, bright yellow; of the willow, hoary.

Sow (307.) small salads twice or thrice on a south border, chervil, corn-salad, cress of sorts may still be sown to stand over winter. (4052 to 4072.) Radish in the last week of the late autumn crop (3520.) Lettuce in the first week for standing the winter under a south wall, and under cold-frames. (3870.) Spinage in the first fortnight for use late in spring. (148.)

Protect cucumbers and melons, at night, by matting or otherwise as the case may be. (316.)

Potatoes (1985.) as in April, culinary herbs and under-shrubs.

Transplant (3070.) all articles intended for use the current autumn, during the first week. The brassicas tribe, leeks, celery, endive, &c. for winter and spring use. Seedling cauliflowers, where you think you can ensure their standing through the winter. Try a bed of sandy loam or lime rubbish under a tree or south wall. (3246) Make plantations of herbs.

Routine culture. Earth up and air in only dry weather. Stick, stop, support, cut down, blanch, and thin where you see it necessary; no time to be lost at this season.

Taking crops. (2050.) Take up potatoes, and do it effectually, especially for pickling cucumbers, onions, nasturtiums, and other pickling articles. Gather herbs and take ripe seed. Remove all decayed bits, branches, and refuse from all crops, which have been taken, so as to preserve order and neatness, and make way for other crops or winter fallows. (3500.)

Destroy weeds. (2076.) Store-room and cellar. Dress, sort, and put up seeds which have been well dried. Finish housing edible bulbs of the alliaceous tribe and potatoes (2588, and 3529.)

4. Hardy fruit department.

Plant (3071.) strawberries for a main plantation, this being the best month in the year for that purpose. (4717.) Pot strawberries for forcing. (3536.) Prepare ground for planting, and towards the end of the month, if the wood of young peach and apricot trees be ready, take the month to remove the manure, in which all crops, which have been taken, so as to preserve order and neatness, and make way for other crops or winter fallows. (3500.)

Routine culture. Provide compost for recruiting old borders and forming new ones. Protect choice fruit, especially grapes, from birds and flies. After the crops, if your trees or compartment borders are gathered, dig and dress the borders. Dress and fork up strawberry-beds.

Take (2520.) peaches, grapes, early apples, pears, plums, &c. the dessert sorts, with fruit-gatherer, and for the kitchen, with the hand gloved. Choose, if possible, dry weather for gathering all sorts of fruit.

Destroy insects, especially acarbus, and guard against wasps and large blue flies. (2576.)

Fruit-room. (2525.) Lay up apples and pears for keeping. In general, the long keeping sorts ripen late in the season.

5. Culinary hot-house department.

Glass case without artificial heat. Sow small salads under hand-glasses or frames in the last week. (4078.) Take off the glasses from cauliflower-plants in all mild days.

Hot-house culture. Attend to late crops of melons and cucumbers; keep up the temperature, and be discreet in the use of water. (3164. and 3271.) Begin to build mushroom-beds, either in or out of doors. This month and March are the two best seasons. Plant suckers and crowns of pines on rotten tan placed on dung, or other fermenting beds or pits.

Pinery. (3262.) You will still have abundance of fruit; attend to what was said in July. Renovate your bark or leaf beds when necessary, and keep up the full heat till your fruit is chiefly ripened off, or
removed (pot and all) to the fruit-room to ripen leisurely. Your young plants will grow faster in this month than in any month of the year.

Late crops of grapes will be coming in, but most of the forcing-houses will now be in a state of rest. Keep off all the sashes, unless you mean to force very early, in which case cover with cloths from the north, and admittance of air from the north, in order to promote a cool, dry atmosphere as best for hybernation.

6. Flower-garden. — Open ground department.

Sow the primula tribe, if not done last month. (6288 and 6288). The seeds of most biennials and perennial plants, sown this month with advantage, provided you can afford protection to them in winter. On the whole, however, it appears better to defer the business till spring, unless with a few sorts which sow at times, a natural time and before they come up, when sown at that season. Among them may be enumerated columbine, agrimony, chelone, &c. If sown now their seeds will come up the following spring, and they will flower the same season. (6455).

Crocus (1855.) by all the modes, but more especially from slips, rooted or unrooted, the starchy part of the plants being the best of a proper texture and maturity for this purpose. Plant crocuses and other bulbs, and such autumn-flowering bulbs as you have neglected to plant early in spring. (6301)

Transplant as in last month. (3078.)

Shelter. (2206.) If the end of the month be wet, hoop and mat such plants as will be injured by over much wet. Among these are the primula tribe and tender annuals planted in groups over the borders; also bulbs, as the tuberous and Guernsey lily, planted or plunged in the borders.

Routine culture. Prepare ground for florists' flowers. Trench and sift the earth where tulips and hyacinths are to be planted, at least three feet deep.

Store-room. See to roots and seeds. (1704.)

7. Flower-garden. — Hot-house department.

Glass case without artificial heat. (2686.) Replace the more tender auriculas in the frames, but keep off the glasses, excepting when it rains.

Hot-beds. See last month. (2687.) Most of the green-house and hot-house plants will now be advanced: remove them to cold-frames, or to the green-house or dry-stove, according to their nature, to harden them gradually. Some may go directly to the dry-stove.

Green-house. The beginning of this month is a fit time to repair, paint, glaze, and clean the house, &c. of every description of house not in crop. Replace some of the more tender plants from the open air at the beginning, and the whole in the course of the last week of the month. Dress them properly for a natural year before it is in the usual method. (See particularly 6036.)

OCTOBER.

Dry-stone. Replace all the succulents and other plants, which you had put in the open air, and arrange every part of your stage for the winter. If your borders are of the natural groups, at least put every genus by itself. (6205.)

Bark, or moist stove. Begin to lessen the stimuli towards the end of the month, in order to harden for the approach of the cold air from the north, which has been taken up and dried. Attend to routine culture. (6888.)

8. Pleasure-ground and shrubbery.

Plant (2077.) evergreens generally; deciduous species in the last week.

Prune (2110.) evergreens all the month: deciduous species, when the leaves are dropped.

Routine culture as in last month. Remove all decaying flowers that do not bear ornamental seeds or berries.

Dress and mow turf, and roll and clean gravel.

Form and repair lawns, or verges, or grassy glades. (2100. and 2101.)

Fruit-trees. (2039.) Sow cherry and plum stones for stocks, also peach and almond stones for the following year. Such plants as require to be sown this month, and which have to be peeled, will be accelerated by using cold water. The stems of auriculas will be better done as other plants. The matting may generally be removed early in the month.

Ornamental trees and shrubs. (6570.) Sow siberian and rose seeds. Plant cuttings of hardy evergreens. Take off layers of the sorts which have been laid two years, or which root well within one season. Plant cuttings of a few of the deciduous shrubs which are mostly hardy, or of tree-currant, ivy, honeysuckle, yellow-berried elder, &c. Take off suckers, and plant them in nursery rows.

Forest-trees. Gather and sow all sorts of deciduous tree-seeds. If you do not sow them, take them to the seed-loft, or rot-heaps for preservation. Plant and prune evergreens, as also the wild cherry, birch, and sycamore. Gather seeds of all sorts now ripe. (6882.)

Thin woods and coppices; and where the trees are too large, them carefully up, if they are large, they should have been previously prepared a year ago. (6555.)

Plant (2077.) deciduous trees generally, and even the scarce and rare species, such as the spruce fir, and Scotch pine.

Prepare for planting by fencing and all the subsequent processes. (6820.)

Operate on ground, and recommence building walls or other works belonging to the department of landscape-gardening.

In the first week: the red-wing (Turdus iliacus) arrives; snakes and vipers bury themselves. Second week: hooded crows (Corvus cornix) and winter ploegons (Pleocephalus) arrive; hen-haenichfines (Fringilla coelebs) congregate, and prepare for migration, leaving their males in this country.

Third week: the snipe (Scolopaz gallinago) appears in the meadows; wild geese (Anas sphyrestris) leave the fens, and go to the meadows.

Fourth week: the tortoise (Testudo graeca) begins to bury himself in the ground, and rooks visit their nest-trees; some larks (Alauda) sing, and

the woodcock (Scolopax rusticola) returns; spider webs abound.

2. Kalendar of vegetable nature round London.

In the first week: strawberry-tree (Arbutus unedo), holly (Ilex aquifolium), China hollyock (Ilex crenata), and China aster (Aster chinensis), in bloom.

Second week: catkins of some species of salix form the asp almost all off; of the Spanish chestnut, yellow; of the sugar-maple (Acer saccharinum), scarlet; of the common birch, yellow and gold; and of the weeping-sugar, gold and brightred colored.

Third week: clematis calycula in flower; some horse-chestnuts and acacias quite denuded of leaves.
Fourth week: various plants, especially annuals, continue in flower; leaves of marsh-elder (Sambucus ebulus), of a fine pink; of stagh's-horn sumach, of a maroon red; of the American oaks, of fine shades of yellow, orange, red, and purple.

Sow (2071.) small salads, legumes, and radishes in the first week. If mild weather continues, they will come in about Christmas. Mazagan beans, and hotspur or frame-peas (3801.), in the third or last week, to see if they will stand the winter. (3616.)

To save seed. Transplant cabbage, savoy, beet, parsnep, carrot, turnip, bulbip and Welsh onions, the last is said to be the cause of the danger of bastardy among the cruciferous family. (3992.)

Protect all new risen annuals, and newly deposited seeds, as also parley on the approach of frost. (2026.)

Propagate (1855.) the alliascic tribe and culinary perennial. Transplant (2070.) endive and lettuce on warm borders, and cabbages in close rows or in beds, to remain in that state till wanted as plants in spring. Cauliflower in the last week, to receive the protection of frames. (3545.)

Routine culture. Earth up and stir the surface only in fine dry weather. Hoe, rake, thin, wean, and lift from beds of winter crops. Protect cauliflower from heavy rains by breaking a large leaf and folding it over the flower. As crews are cleared, dig from the vacant ground the proper leaves of parsley, and horse-radish of two summers' growth. Preserve them in dry sand.

Protect (2206.) fig-trees as soon as their leaves have fallen. Shield late fruits from frost by matsing. Immerse pots containing plants intended to be forced, into dry old tan or ashes to save their roots from freezing. (2071.)

Prune (2110.) all sorts of fruit-trees excepting the raspberry, elder, and fig, which being trees of much pith, or medulla, are apt to drop back from the point of the veteran branch, when removed this season, and are therefore better left till spring.

Routine culture. Prepare ground for new plantations. Dig and ridge up where the trees are already planted. Water-dress strawberry-beds.

Take (2290.) grapes, apples, pears, and other fruits.

Fruit-room. (2298.) Lay all fruits first here till thoroughly dried, and then barrel up the longest keepers, and remove them to the fruit-cellar.

5. Culinary hot-house department.

Glass case without artificial heat. (2896.) Plant lettuce and cauliflowers under frames, to stand the winter. Sow small salads in the second week, and last month under frames for winter-glasses. Hot-beds and pits. (3578.) Keep up the declining heat of such beds as have not yet ripened off their crops. Dress those which have done bearing, and put them under frames; or put them on straw or cauliflowers, or mint and other herbs for forcing, by putting them in pots or boxes. Get up mushroom-beds if not done in September. Plant them in July, as they are taken off. Cover well at nights. (2206.)

Pinery. This is a general time for shifting and replanting the bird-bed. Do not put the plants into very large pots, as they will not grow much in winter. Till the last week of the month your plants will grow rapidly. (2070.)

Prune and in general cleanse and repair the houses and fluxes, mend broken glass, and paint the whole when necessary. (2095.)

6. Flower-garden.—Open ground department.

Sow (2071.) annuals in pots, for prolongation, in cold frames and pits, and some of the harder sorts in warm borders, to come in early next spring, if the winter prove mild. The sorts fit for this are larkspur, adonis, belvedere, pansy, persicaria, annual stock, and strawberry blite. Propagate (1855.), but chiefly at this season by dividing the root, as of daisies and of other edging plants, irises, &c.

Plant most of the border-bulbs about the end of this month, or you may sow even plant Dorcis' anemones in properly prepared beds. (2077.)

Transplant (2075.) biennials and perennials, in the flower-nursery, to stand till the spring. Strong plants moved where they are finally to remain. (6490. and 6505.)

Protect (2206.) auriculars, carnations, and other florists' flowers; as the heat of the rooms may dry up or even destroy them. Protect your Peregrine's eyes of a critic and an enemy, or even of a stranger. (7438.)

7. Flower-garden.—Hot-house department.

Glass case without artificial heat. (2896.) Begin about the middle of the month to fill frames and pits with pots of mignonette, stocks, &c. for prolongation. (2071.)

Hot beds and pits. (3678.) Roses which have been some time in a state of hybernation and in the shade, may now be put in bottom heat, as may hyacinths and other bulbs. Water-glasses may now be brought into use. Observe, in the first place, to plant the bulbs in earth for a week or fortnight, which will make them strike roots more freely, and then take them up and put them in the water-glasses. Force them forward a week or two in frames, before you remove them to the drawing-room. Continue to plant some every fortnight for succession. (6490.)

Green-house. (6211.) Replace all your plants, if you have not already done so. All your winter's credit depends on what you do this month. Give air night and day, unless the thermometer drop to 35 degrees. Water sparingly. (6211. to 6213.)

Dry-stove. (6176.) Apply fires towards the end of the night, so as to keep a medium temperature, with fire-heat of 46 or 48 degrees. Arrange the plants for the winter. Pot and set in bulps of most sorts.

Bark, or moist stove. Lessen your temperature by degrees; and also your air and water. A good medium heat for this month will be 70 degrees, which will require fire-heat, even if the bark-bed is in full force. (6214. to 6216.)

8. Pleasure-ground and shrubbery.

Plant (2077.) all the harder shrubs and trees where the ground is not apt to be rendered very wet during winter: very delicate sorts leave till spring. This is the best season for planting. (2071.)

Prune (2110.) all the evergreens, and especially, in the beginning of the month. Deciduous sorts as soon as the leaves fall.

Routine culture. Clear away all refuse, weeds, and decayed stubs. Roll, how, sweep, hoe, weed, and remove moss and worm-casts. Form and repair lawns as before. (2100. and 2101.)

Fruit-trees. Sow for stocks as directed for last month. The plum, cherry, almond, medlar, apple, pear, quince, barberry, service-tale, walnut, filbert, and common hazel-nut, may now be sown to greater advantage. If in spring, provided you can keep the vermin from them during winter. Lay the grass
mulberry, or any other sort generally propagated in this way. Plant cuttings of elder; but it is rather too late for the ribs tribe. Remove raspberry suckers. Remove fruit-trees to their final situations, as soon as they have lost their leaves. This month, in all dry situations, is the best month in the year for transplanting fruit-trees.

Ornamental trees and shrubs. Sow the seeds of deciduous sorts in the pot-deep; lay deciduous sorts as their wood ripens. Plant out in nursery rows; shelter where requisite. (2206.)

Forest trees. Sow most sorts, as directed for last month, in a place where you wish to hold them. Gather haws, sea and holly berries, hips, &c. and take them to the hot-hep. Lay and propagate by cuttings some of the timber-growing willows and poplars. Plant and prune in the nursery lines as required. (6/83. to 70/37.)

Plant (997.) generally as long as the weather is mild; but prefer the spring for very wet, late, bleak situations. (6/93. to 70/37.)

Thin, prune, and fell generally, but do not fell barking-trees, or remove thinnings of the oak, larch, &c. so large as to be worth barking.

This month is as directing for last month.

This is a very fit season for draining, which may be continued in all weathers, when men can work out of doors. The planting season returns. In this way the men may be kept on without loss either to themselves or you. (8/17.)

Operations on ground should be carried on vigorously; but buildings should be completed, if possible, by the middle of the month.

November

In the first week: the buck (Cervus cprillus) grunts.

Second week: the golden plover (Charadrius plus-viella) appears.

Third week: snails (Helix) and slugs (Limax) but themselves.

Fourth week: greenfinches (Fringilla montifringilla) flock; the winter moth (Gometra brunaria, Sam.) and the common flat-bodied moth (Gometra appianna, Sam.) appear in gardens about the end of the month.

2. Kalender of vegetable nature round London.

In the first week: a few plants in flower, by accident, chiefly annuals, according to the season.

Second week: the fungus helvella mitra appears; laurustinus in flower.

Third week: callaehus precox in flower.

Fourth week: some primroses show flowers at this season; and some plants, unnaturally in flower, still continue if the weather be temperate.

Sow (2/71.) short-top radishes on a warm border for the chance of obtaining an early spring crop. (5/76.) Peas and beans as directed for last month. (3/91. and 2/16.)

Protect (2/06.) celery, endive, artichoke, seakale, potatoes left in the ground to be taken up as wanted, and any other outstanding edibles roots by litter or leaves. Radishes, and parley with fronds of fern. Cauliflowers by hoops and mats.

Propagate (1/83.) perennial herbs, if not done last month.

Transplant (2/79.) any thing you have omitted in October.

By the culture. All operations on the earth, excepting digging and trenching, must be performed only in fine dry weather. Dress artichoke and asparagus beds. Take up endive, brocoli, and cauliflower, and lay them flat in dry ground, or in some of the ways described. (2/93. &c.) Guard against the damping off of cauliflower plants, and weed all scudding crops. Dig, trench, and manure.

Take up all edible roots, which you intend to preserve, and remove them to the root-cellar.

Destroy (2/87.) insects, and particularly slats, it this month.

Root-cellar. (2/99.) Keep out the frost, if it sets in severe; and equally so water, from above or below.

Store or seed-room. (1/76.) Turn over edible roots kept in the dry, as the alllicaceous tribe, and pick out decaying bulbs. See to your seeds.

Ice-house. (1/76.) Fill the ice-house if the frost is sufficiently strong.

4. Hardy fruit department.

Plant (2/77.) all sorts of fruit-trees, as directed for last month. Choose dry weather. Water to settle the roots where required, and mulch (2/88.) both root and stem, where you wish the trees to do well. Mulching the stem is particularly useful for very soft soil standards, and especially for the pithy-wooded sorts.

Prune (2/110.) the vine, and other very hardy fruit-trees; the apricot, peach, and peachberry had better be left till after flowering.

Routine culture. Dig and dress whereever pruning admits; or where you have not been able to overtake the work last month.

Take away apples and pears as still remain on the trees during the first week; dry them well in the fruit-room, and then barrel or jar up the longer lasting sorts for the cellar.

Fruit-room. (1/88.) Examine such bunches of grapes, and branches of succulents and currants, which you have hung up to preserve the fruit; and pick off all decayed and shrivelled parts.

Look over all the other fruits, and attend to medlars, quinces, and services.

5. Culinary hot-house department.

Glass case without artificial heat. (3/88.) Sow small salads and peas and beans, either to transplant or to remain after moving the frames. Transplant lettuces and cauliflowers from frames to be covered with glass and glasses. Attend to air and removing decayed leaves.

Hot-beds and pits. (2/78.) Sow small salads, force mint, and other herbs. Try sowing of radishes on a moderate hot-bed. Transplant lettuces from the cold-frames to force them forward. Begin to force asparagus six weeks before the expected demand. Build mushrooms-beds; if under cover, it will be better.

Piney. (3/79.) Moderate every stimulus to vegetation: because, for the proper well-being of plants, it is requisite they should all go on in harmony. Heat, air, and water, art can supply; but light, in any thing like adequate quantities for vegetation, is beyond the power of man: therefore let your heat, air, and water stand in an equal proportion to the light.

Forcing-houses. Some begin this month; if so, begin the usual course. Dig and dress the borders; prune as you please the plant house, &c. not done last month, which is much the best time. (2/83.) Set in strawberries. (5/33.)

6. Flower-garden. — Open ground department.

Plant (2/77.) dry roots of border-flowers. (3/92.) Transplant (2/79.) biennials at the beginning of the month, if the weather is very fine: but this work is better deferred till spring. (3/64. and 1/60.) Heat, air, and water, art can supply; but light, in any thing like adequate quantities for vegetation, is beyond the power of man: therefore let your heat, air, and water stand in an equal proportion to the light.

Protect (2/06.) tender roots by litter, leaves, tan, ashes, or landing up trees by mats, or straw covered with mats or nets. Take care of seedlings.
8. Pleasure-ground and shrubbery.

Plan (207d) deciduous trees, and shrubs of the hardier kind so long as the weather continues dry.

Plan and cut hedges. (2110)

Protect (206d) American trees, as magnolias, and shrubs not yet fully acclimated, as the Chinese rose. Roll, mow, and sweep turf. Attend to fallen leaves. (6195, 6265)

Turf may still be laid, but it is now too late to form or repair lawns by sowing grass-seeds. (2101.)

Prepare for planting, by levelling, digging, trenching, &c. (1861 to 1871.)

Fruit-trees. (436l.) Plant only in mild and rather dry weather, or in a box, with water to settle the earth about the roots, and stake as circumstances require. Forward delayed work as to fruit-trees, for after the middle of the month it is better not to touch them till February.

Ornamental trees and shrubs. Complete what should have been done last month, as to planting, laying out, making borders, &c. (746l.) Prune the more hardy sorts in the lines, and protect such as are tender by the usual means.

Forest trees. Finish sowing the larger seeds before severe weather sets in. Complete all other nursery operations for the season, if possible. Pruning the plants in lines may be the last operation. Gather cones, acorns, nuts, keys, and berries for immediate use, and have them ready according to their natures, and your skill and circumstances. (6933 to 7037.)

Plant in all temperate weather, and moderately dry situations. (207d)

Thin, fell, and prune deciduous trees, as in last month. Cut, plant, and repair hedges; and more especially the hawthorn kind. (6917)

Deciduous trees of every description, excepting mor- tar-walls, may now be attended to; but avoid them till building in December and January, even the simplest wall. Frost is certain at this season, and its effects equally so.

Operate on ground, water, rocks, woods, and timber creations; but by no means on buildings where mortar is used.

DECEMBER.
KALENDARIAL INDEX.

5. Culinary hot-house department.

Glass case without artificial heat. (2866.) Sow small salads, radishes, and lettuce; if the weather proves mild they may do some good. Weed, take off decayed leaves, and give abundance of air in dry weather. Protect, in severe frosts, by mats or litter. Hot-beds and pits. (2978.) Begin to force asparagus, sow small salads, and transplant lettuce to be forced forward. Use the transplanter, in order that no check may be given, or any occasion for watering thereby. Prepare cucumber-beds; or if you have begun see to them. Light is the grand thing to be attended to, for heat, air, water, and earth you can command at pleasure. Force mint, attend to mush-rooms, and compost-making; procuring earth, manures &c. Cover up at nights with all care; but avoid damps, by always giving a little air on fine days, and all night, when there is danger of steam of dung.

Parlour. (2875.) Keep a steady heat; but little air or water will be wanting, excepting to the kidney-beans and strawberries which you set in last month.

Porcelain-houses. (2940.) Go on with the routine culture, for houses which you have begun to force; and dig and prepare the borders of the others, but it is too late for pruning or repairs.

6. Flower-garden. — Open ground department.

Protect as directed for last month, and be liberal in the use of ashes, rotten tan, litter, &c. to the roots of the more tender plants; as to beds of florists' bulbs, tender and half-hardy shrubs, as China roses, hydrangcas, &c. where such plants can be ventured in the borders.

Routine culture. Prepare composites, manures, and simple soils, and turn them over frequently. Much of the value of all composites and soils, at least for the florist, depends on their being sweet and mellow, which is only to be attained by time and frequent turnings. Attend to neatness in the application of litter, ashes, and other protecting materials.

Store-room. See that the frost is completely excluded. (1704, 1705.)

7. Flower-garden. — Hot-house department.

Glass case without artificial heat. (2866.) Attend to alpines, and florists' flowers in frames; also to annuals, as directed for last month.

Hot-beds and pits. (3078.) Go on forcing shrubs and flowers, and blowing bulbs in water; renovate by linings, where necessary. If you have begun in October to force roses, you will have them as well as bulbs in blow by the middle of the month. See to bulbs in water-glasses, and take care to keep up a succession of roses, bulbs, and most popular forcing-flowers and shrubs. (2217. to 2218.)

Green-house. (6211.) Minimum temperature 42 degrees, maximum 44 degrees, with fire-heat. Water sparingly; give air freely in good weather, and remove decayed leaves as they appear.

Dry-stove. (6716.) Minimum temperature for this month 43 degrees, maximum, with fire-heat, 50 degrees. The more severe the weather out of doors, give less water within; but give air freely in fine weather.

Bar, or moist stove. (6214.) Keep a medium heat of 53 degrees, or 58 degrees, and lessen water and air. Attend to routine culture; but the grand thing at this season is, to keep the fire-heat as regular as possible; for the ratio of increase of heat from flues, after they are heated to a certain extent, is such as often to overheat the house, and scorch or desiccate the plants: hence, in our opinion, one of the many advantages of adopting steam, by which the pipes can never be heated much above 200 degrees.

8. Pleasure-ground and shrubbery.

Plant as in last month. (2077.)

Prune (2110.) in fine weather.

Protect as before. (2206.)

Routine culture. Take up leaves, and sweep them from the lawns and gravel. Repair walks, and roll them; see that water stand on no part of their surface.

Lay down turf, if you cannot help it; but this is not a good season; September and March are the best. (210.)

Prune for planting by trenching, digging, &c. (1570.) Rods and poles for tying up plants and for twining, spray or sticks for sticking climbers, as the sweet-pen, &c. (1516.)

Tree-fruits. (4361.) Complete neglected work as far as weather will permit; but if the season is severe, defer it till February. Prepare tallies, &c.

Ornamental trees and shrubs. (6529. and 6548.) Finish delayed work, and attend to protecting tender sorts. See to the seeds in store, and prune only in very fine weather. Prepare tallies, labels, sticks, stakes, poles, rods, spray, fronds, and other materials of culture and management. Collect composites, earths, and manures, and turn over those you have got, so as the frost may thoroughly penetrate them.

Forest trees. (6983.) Attend to the rot-heap, seed-look, and compost-ground; and plant, or take up, or prune only in fine weather: much depends on the season, and other circumstances. (6884.)

Plant (3077.) only in fine weather, unless thorn-hedges; or large trees of common sorts, with balls of earth.

Pelt and prune (6941. and 6884.) where the trees are not for transplanting, nor of the baking sorts.

Thin out coppice-wood for poles, stakes, &c. (6912.)

Prepare for planting by the usual processes, and by fencibg and draining. (6817. and 6850.)

Operate on ground and rocks, but not on build- ings.
GENERAL INDEX.

N. B. The Numbers refer to the Paragraphs, not to the Pages, excepting in the case of the List of Authors, where they refer to the page and the year in which the Author published: in such cases the word page, and letters A. D. are prefixed.

Acer, pseudo-platanus and plataniodes, the common and other maples, 7076, and 7089.
Aceras, gynan. monan. and orchidacee, a H. peren. Eng, which thrives best in light loam and chalk, and is only to be raised by seeds.
Acetaria, plants, 3063.
Acchania, monad. polyan. and malvaceae, S. tr. Jamaica, which grow in common soil, or in loam and peat, and cuttings root in sand under a hand-glass.
Achar, Professor Francis, page 1126.; his works on gardening, A. D. 1738.
Acathis, milfoil, syngon. polyg. equal. and eorynhibere, H. peren. Eur., which grow in common soil, and are readily increased by dividing at the root.
Achras, sapsota, pentan. monog. and sapotes, S. tr. Amer. requiring a rich, loamy soil, and cuttings root in sand under a hand-glass.
Achyrantarhes, pentan. monog. and amaranthaceae. The S. and G. tr. India, thrive in any rich soil, and cuttings root freely. The an. species should be sown in a hot-bed.
Acidom, monone, polyan. and euphorbiaceae, a S. tr. Jamaica, which will grow in loam and peat, and may be increased by cuttings in sand under a bell-glass.
Acisantha, decan. monog. and salicaceae, a S. tr. Jamaica, which may be treated like acidom.
Acmella, syngen. polyg. frustran. and corymbiferae, the S. and S. Amer. an. should be sown on a hot-bed, and the H. an. in the open garden.
Aemna, Virginia hemp diice pentan. and chenopodae, a H. an. N. Amer., to be treated as such.
Acromium, wolf’s bane, polyan. trig. and ranunculaceae, H. peren. S. Eur. of common culture.
Acorus, hexan. monog. and aroidene, H. peren.
Acorus, hexan. monog. and aroidene, H. peren.
Acorus, hexan. monog. and aroidene, H. peren.
C. B. S. and Amer., which grow well in loam and peat, and cuttings taken off at a joint, root freely. The H. peren. will grow in common garden-soil, and are continued y cuttings.
Acalpy, monog. monac. and euphorbiaceae, S. and H. an. E. Ind. and N. Amer., the S. an. should be sown in pots in a hot-bed, and the H. an. in the open garden. The soil for both, loam and rotten dung, or leaf-mould. 
Acanthus, bear’s breech, didyn. angios. and acaen-thaceae, a S. tr. E. Ind. and H. peren. Eur. Both grow in common soil, and divide readily at the root.
Acanthaceae, syngen. polyg. aqual. and cyanorrhaceae, a H. peren. and H. an. S. Eur. Both thrive in loam and peat, and are increased by seed or dividing the root.
Acrismum calomelanos, 6739.
Actaea, monad. monog. and ranunculaceae, H. pe-

Acera, Acer, maple, polygam. monac. and acere£B, H. tr. Eur. and N. Amer., which grow in any soil, and propagate by layers or seeds, and some species by cuttings.
loam, and cuttings strike in sand, plunged in heat under a hand-glass.

Addington Place, Surrey, 7277.

Adelia, dicaeum, monad, and euphorbiaceae, a S. tr. Jamaica, which may be treated like adansonia.

Adenandra, monog. and ter. B. tr. C. B. S. which grow in sandy peat, and the young tender tops made into cuttings, and planted in sand, will root under a bell-glass without bottom holes.

Adenothera, decan. monog. and leguminosae, S. tr. E. Ind. which grow in loam and peat, and large cuttings with their leaves shortened, will root in a pot of sand plunged in heat under a hand-glass.

Adiantum, maidenhair, cryptog. filices, and filiceae, G. tr. N. tr. peren. Madeira and Brazil forms, which grow well in loam and peat, and propagate by dividing the root or by seed.

Aegialitis, tetr. monog. and globulariae, a S. tr. China, of easy culture in loam and peat.

Adoxa, octan. tetrag. and saxifragae, a H. peren. Brit. a diminutive plant, which does well in pots in common soil.

Adrianthe, gardens of, 307.

Aegiphila, tetr. monog. and verbenaceae, S. tr. W. Ind. which thrive well in light loam, and cuttings root freely under a hand-glass in heat.

Aegle, time-ripe quince, polyan. monog. and aurantiaceae, a S. tr. E. Ind. which requires a rich loam, and is propagated by ripened cuttings planted in sand, without shortening the leaves, and plunged under a bell-glass in heat.

Aegopodium, goutweed. pentan. dig. and umbelliferae, H. peren. Brit. of the easiest culture.

Aegilops, air-plant, gynan. monan. and orchideae, S. peren. China, parasites, which may be hung up in a basket of moss or pieces of bark, or fixed by moss and bandages to the trunk or bark of a tree, — according to the Hon. Mr. Herbert's treatment detailed, 6736.

Aegina, pentan. monog. and amaranthaceae, a S. tr. and S. bien. W. Ind. which grow well in rich, light earth, and cuttings strike freely.

Aegyptiumena, diadeal. decan. and leguminosae, a S. tr. W. Ind. which requires rich loam, a good deal of heat, and is propagated by cuttings under a bell-glass in bottom heat. The S. an. and H. an. India and Amer. may be treated as tender annuals.

Aechmea, horse-chestnut, heptan. monog. and aceraceae, H. tr. Asia and N. Amer. which prefer light, deep soil, and sheltered situations, and are propagated by cuttings or suckers.

Aesculus hippo-castanum, the common horse-chestnut, 7126.

Afflum, Casimiro, his works on gardening, page 1128. A. D. 1787.

African almond, brabejum stellatulfomum.

African bean, fanal, fanalanieae camphorae.

African fruits deserving cultivation, 6918.

African lilu, — see Agapanthus.

African marigold, tagesis ereceta.

African persicaria, friand, hexan. monog. and home- roccidaleae, G. peren. C. B. S. which thrive in loam, and a little rotten dung, and are propagated by dividing the root, or by seed.

Agaonema, campestre, garden-mushroom. See this and various other species of agaricus described, 4339. Culture of the garden-mushroom, 5494; which may be ascertained, 5419, 3410; preserving on peat, 5412; procuring artificial spawn, 5413; propagating, 5415; methods of making mushroom spawn, 5419, 3425; raising the spawn in the open air, 5434; preparing the dung, 5435; forming the bed, 3436; moulding planting, covering the bed, 3437; culture on shelves, as in the Forman manure, 3438; compost, 3455, making, spreading, earth¬ing, subsequent treatment, 3436; renewing ol old beds, 3440; growing mushrooms in pots, boxes, etc., with dung, 3444; culture in melon-beds, 3445; in old hot-beds, 3447; in pits, 5418; in dark frames, 5449; in a cellar, 5470, detailed 3452, 3467.

Agapanthus, monog. and diosmeae, G. tr. C. B. S. soil, a sandy peat; propagated by cuttings in sand under a bell-glass, but not plunged in bell-glass.

Agave, hexan. monog. and bromelieae, D. S. and G. tr. and peren. S. and N. Amer. soil, a rich loam; propagated by suckers.

Agaves, the Lomet's villa at, 176.

Ageratum, syngean, polyg. squa. and corymbiferae, G. tr. requiring a light, rich soil; propagated by cuttings under a bell-glass. The H. an. is of common culture.

Aghinius, a seat in Tyrone, 7769.

Agrimonia, see Lomatium, his works on gardening, page 1123. A. D. 170—

Agrimonia, agrimony, dodocan. dig. and rosaceae, H. peren. Eur. and N. Amer. of easy culture.

Agrimony, — see Agrimonia.

Agrostemma, rose-campion, decan. pentag. and caryophyllaceae, H. peren. and an. of common culture.

Agrisotis, bent-grass, trian. dig. and gramineae, a S. peren. E. Ind. and H. peren. and an. Eur. of the easiest culture.

Agrimony, see the blood-plant for bitter fruits, especially the orange tribe.

Ailanthus, polyg. monog. and terebinthaceae, a S. tr. and S. bien. W. Ind. which grow in common soil, and are propagated by cuttings of the roots.

Aimfels, a seat in East Lothian, 7639.

Air, its nature and properties, 1216.

Airus, see Africium.

Aira, hair-grass, trian. dig. and gramineae, H. peren. and an. Eur. of the easiest culture.

Air plant near Stirling, 384.

Alitas, monad. octan. and meliacae, G. tr. an. C. B. S. soil, sandy loam and peat; propagated by cuttings of young wood, in sand, under a bell-glass, and plunged in heat. Avoid planting too close, and wipe the glass frequently, as they are apt to dry off.

Aigua, bugle, didym. gymnos. and labiateae. H. peren. of common culture.

Akee-tree, bighia spadix.

Alamanni, Luigi; his works on gardening, page 1128. A. D. 1586.

Alangium, polyan. monog. and myrtaceae, a S. tr. E. Ind. soil, loam, and peat; propagated by cuttings in sand, under a hand-glass in heat.

Alamandra rhizomus alaternus.

Alibonico, J. H. his works on gardening, page 1125. A. D. 1705.

Albica, hexan. monog. and asphodeliaceae, G. peren. C. B. S. soil, sandy loam, and vegetable mould; propagation by offsets; or by leaves taken off with a scale of the bulb, and carefully planted.

Alberch, palace and gardens in Spain, 291.

Alchemilla, ladies' mantle, tetran. monog. and rosaceae, H. peren. and an. Eur. of common culture.

Alcina, syngen. polyg. necess. and corymbiferae, a G. an. Mexico, of easy culture.

Alcoive, 1810.

Aldeban, pentan. monog. and boragineae, a H. peren. Magellan, of common culture.

Alderney. Alsus.

Alderney Park, Cheshire, 7590.

Aldworth Hall, Yorkshire, 7389.

Aletris, hexan. monog. and homeocollidaceae, H. peren. Sue Amer. requiring a peat soil and shady situation, and propagated by offae from the roots.

Aleuccus, monog. monad. and euphorbiaceae, a S. tr. Vere in the Scilly Isles; soil, a rich loam; ripe cuttings, with their leaves on, strike in sand, under a hand-glass.

Aleurites — see Smyrnium.

Alexandrian laurel, ruscus racemosus.

Alisma, water-plantain, hexan. polyg. and alismaceae, H. peren. marsh plants, and aquatic of easy culture.

Alison, the Rev. A., his Analysis of the Principles of Design, 7160—1702.

Allamanda, pentan. monog. and apocynaceae, a S. tr. Guiana; soil, a rich loam; cuttings strike freely in moist peat.
Altantic, cryptogam, filices, and filiceae, a G. p. Amelius, 6154; & soil, loamy, peat, and; and propagation by dividing the root or seed.
Alberton Manleverer, a seat in Yorkshire, 7382.
Allaisceous plants, 3510.
Alkaline waters, 5906
Allinia, tetran. monog. and cynogineae, H. peren.
N. Amer. which grow in common soil; and cuttings. 3845.
Allium radiatum, 5906
Allium porrum, the leek, 3811.
Allium sativum, the garlic, 3811.
Allium salsilla, the leek, 3811.
Alstroemeria, Alston.
Alumnae, Althorpe, Althidia.
Alstromeria.
Amaliscus, ambrosia, an. hippocrepis, 5977.
Amber-tree, and leguminosae, S. tr. W. Ind. requiring a light loam; and cuttings, not deprived of their leaves, root freely under a hand glass in a warm situation.
Amythestia, dian. monog. and labiateae, H. an. Siberia, of common culture.
Amnannia tetran. monog. and siliateae, S. an. and H. tr. of easy culture.
Ambrosia, pantan. leguminosae, 8. peren. Sicre Leone, reedy marsh plants.
Amorpha, bastard indigo, diadel. dian. and leguminosae, F. and H. tr. Amer. which grow in common soil, and are increased by cuttings planted in autumn, in a sheltered situation.
Amphill Park, Bedfordshire, 7549.
Ampton Hall, Suffolk, 7549.
Amsinckia, tr. monog. and apocynaceae, H. peren.
N. Amer. which grow in common soil, and are increased by cuttings or dividing at the root. 7549.
Amygdalum, monog. leucocarpum, a G. tr. and H. tr. Persia and Eur. requiring rich loam, and which may be propagated by seeds, layers, grafting, &c.
Amygdalus communis, and amara, the sweet and bitter almonds, 4542.
Amygdalus persica, the peach-tree, 4542; flatpeach of China, and. 3830.
Amygdalus var. nectarina, the nectarine-tree, 4542; to force the peach and nectarine, 5963.
Amyris, octan. monog. and terebinthaceae, S. tr. S. Ind. an. soil and pear cuttings root freely in sand under a hand-glass.
Anabasis, pantan. dig. and cnicopodium, a G. tr. Spain, which grows well in loam and peat, and cuttings in sand under a hand-glass without bottom heat.
Anacamposerus, dododon. monog. and portulacceae, G. tr. and H. tr. Spain, which are propagated in sandy-loam and lime-rubbish, and cuttings root readily in similar soil.
Anacardium, cashew-nut, monoec. monog. and terebinthaceae, a G. tr. Ind. soil a light loam, and cuttings from ripened wood, not deprived of their leaves, will root in sand under a hand-glass.
Anagallis, pimpernella, pantan. monog. and prunulae, a G. an. and bienn. and H. peren. and an. Eur. of all culture increased, either by seeds or cuttings.
Anagris, bean-treefoil, decan. monog. and leguminosae, a G. and F. tr. Spain and Tenerife, soil loam and peat, and cuttings will root in sand under a hand-glass.
Anarrhinum, din. angios. and scrophularineae, a H. bien. of Jonquil culture.
Anastatica, rose of Jericho, tetrad. silic. and cruciferae, a H. peren. Levant, which will grow in common soil, and cuttings under a hand-glass root freely.
Anchoya-pear, griss caulifora, 5973.
Anchusa, bugloss, pantan. monog. and boragineae, G. and H. bien. and peren. Eur. and C. B. S. which grow freely in common soil, and are increased by cuttings or seeds.
Anderson, James, Ll. 130. 140. a British writer on gardening, page 1108. A. D. 1777.
Andersonia, pentag. monog. and eparideeae, a G. tr. N. Holl. which grows freely in peat soil with the pots well drained, and not overwatered; young tops made into cuttings, root in sand under a bell-glass.
Andraceae, bastard orbicule, monoe. gynae. and euphorbiaceae, H. tr. Italy, of common culture.
Andreas, Mr. Isaac, an emigrant of the pine-apple at Lambeth, 2712.
Andreas, Henry, a British writer on gardening, page 1112. A. D. 1798.
Andromeda, decan. monog. and ericaceae, S. G. and H. tr. N. Amer. E. Ind. and Eur. which prefer peat soil, and cuttings strike in sand under bells or hand-glass, but the North American sorts make plants more rapidly by layers, 6562.
Andropogon, polygam. monoe. and grassineae, S. G. and H. peren. E. Ind. and Eur. grasses of easy culture.
Androsace, pentag. monog. and prunulae, H. peren. bieen. and an. Eur. which thrive best in small pots in a peat soil, and prefer the pots being well drained; they are increased by seeds, or dividing at the root.
Andry, a French author on gardening, page 1116. A. D. 1707.
H. tr. which grow in common soil, and ripened cuttings in a hotbed situation; and H. peren., of common culture, and increased by seeds.

Aranjuez, a palace and gardens in Spain, 794.

Aratro, in the North of England, A. tr. Chili and Norfolk Island, which grow in sandy loam and peat, "and cuttings may be rooted, though with difficulty, taken off at a joint in right weather, and planted in a pot of sand under a hand-glass, but not in heat." (Sweet.)

Arboretum of the Hackney nursery, 7555.

Arbocultural catalogue, 7035.

Arboriculture, 6742.

Arbors, 1811.

Arctogal, strawberry-tree, decan. monog. and eri- cine, G. and H. tr. Eur. which grow best in two thirds of peat and one third of loam; they are increased by layers in winter quarters, and A. unedo commonly by budding or inarching.

Archangel, — see Angelica.

Architect, horticultural, 7602.

Architecture, origin of the different styles of, 7934.

Architecutiste, 110.

Arctopus, polyg. diice and umbelliferous, G. peren., C. B. S. which grows in loam and peat, and is increased by seeds.

Arctotis, synen. polyg. neees and corymbifer, G. peren. tr. and an. C. B. S. which grow in loam and peat, and are increased by cuttings, or dividing at the root.

Ardracan Palace, in Eastseathe, 7601.

Ardecan, Jean Paul, de, his works on gardening, page 1339, A. D. 1765.

Ardisia, pentan. monog. and myrsine, S. tr. and G. tr. E. and W. Ind. which grow in loam and peat, and cuttings root freely in sand under a hand-glass, in moist in heat.

Ardinia, pentan. monog. and apocynem, G. tr. C. B. S. which thrives well in peat and loam, and cuttings root freely under a bell-glass in sand.

Areca, calypoge-tree, monog. monad. and palmes, S. tr. E. and W. Ind. palms which grow in light sandy loam, and like others, can only be raised from seeds.

 Arenaria, sand-wort, decan. trig. and caryophylleum, a G. peren. and H. peren. and an. Eur. all the species grow best in sandy loam and peat, and are increased by cuttings by seeds.

Arethusa, gynan. monad. and orchides, a G. peren. N. Amer. a bulb which grows best in two thirds peat and sand, and thrives in the open ground, and requires to be kept moist as a marsh plant.

Areia, pentan. monog. and primulaeace, H. tr.

Areia, pentan. monog. and primulaeace, H. tr.

Areia, rockwork plants, which grow in loam, sand, and peat, and are increased by dividing at the root.

Argemone, polyan. monog. and papaveracee, H. an. and Amer. of common culture.

Argentella, fig-gardens of, 780.

Argyleshire, gardens of, 7649.

Aristea, trian. monog. and irideen, G. peren. C. B. S. bulbs, which thrive in sand and peat, and are increased by dividing at the root.

Aristolochia, birth-wort, gynan. hexan. and aristoco- chiae, S. and G. tr. Ind. and Amer. climbers and twining plants, which grow freely in light sandy loam and cuttings strike freely under a hand-glass: the H. tr. grow in common soil, and are increased by dividing at the root.

Aristoteche, French author on Gardening, page 1116.

A. D. 1677.

Artemisia, dodecan. monog. and rhymeen, H. tr. Chem. which require a sheltered situation; but will grow in any common soil, and ripened cuttings, planted under a glass, will root freely.

Armagh, gardens and residences of, 7682.

Armenia, apricot and rosace, H. tr. Eur. of which there are two species, the Siberian, an ornamental shrub, propagated by budding on plum-stocks, and the common fruit-bearing apricot, prunus armeniaca, 4322.

Armeria, thift, pentan. pentag. and plumbeaceae, a H. tr. and H. peren. Eur. which grow well in common soil, and are increased by dividing at the root. Armeria vulgaris, the common thistle, is a G. peren. of a good size.

Arnica, synen. polyg. super. and corymbifer, H. peren. Eur. which grow best in light loam, and are increased by dividing at the root.

Arnipogon, cheney's beard, synen. polyg. equal and cichoraceae, a H. peren. and an. Eur. of common culture.

Arm's orval, a seat in Middlesex, 7580.

Arundel, a seat in Sussex, 4321, by a British writer on gardening, page 1099. A. D. 1592.

Arrachaca, — see Ajinn.

Arran, gardens of, 7593.

Arreglins, Stephano, his works on gardening, page 1138. A. D. 1766.

Arrow-gras, — see Triglochin.

Arrow-root, — see Sagittaria.

Arrow-root, — see Maranta.

Artedia, pentan. dig. and umbelliferous, a H. an. Amer. of common culture.

Artemisia absinthium, wormwood, 4937.

Artemisia dracunculus, tarragon, 4653.

Artemisia, wormwood, syn. polyg. super. and cor- ymbiferum, G. F. and H. tr. peren. bien. and an. Eur. and Amer. all of easy culture and propagation.

Arthropodium, hexan. monog. and asphodelacee, a G. peren. N. S. W. soil a sandy loam; and propagation by dividing at the root.

Arthur's Seat, a hill at Edinburgh, how to improve by a plea by seeds, 7317.

Artichoke, — see Cynara.

Artiste jardinier, 110.

Asaraceae, the broad-fruit tree, monco. moun. and urticaceae, S. tr. S. Sea. Isl. and Ind. which thrive well in light loam, and propagate readily by cuttings, with their leaves entire.

Asarotus incisa, the common broad-fruit tree, 9014.

Arun, monco. polyan. and aroeides, S. tr. and peren. and H. peren. Eur. Ind. Amer. all of which thrive well in common soil, and are propagated by dividing the roots; or the woody sorts by cuttings.

Artindel, Saxe, Sussex, 7532.

Asarabacca, — see Asarum.

Asarum, asarabacca, dodec. monog. and aristolochie, H. peren. Eng. and Amer. of common culture.

Asclepias, swallow-wort, pentan. dig. and asclepla- deen, G. peren. which thrive best in peat and loam, and cuttings root readily under a hand-glass. The H. peren. are of easy culture.

Asclepias, diadel. polyan. and hypericinum, G. tr. and peren. N. Amer. which thrive well in peat and loam, and are readily increased by cuttings taken in the young wood and planted under a hand-glass.

Ash-tree, — see Fraxinus.

Ashbrooke, a seat in Kilkeny, 7556.

Ashbury, seat in Sussex, 7531.

Ashcombe, a seat in Wiltshire, 7596.

Ashes, proportion in which they are afforded by the combustion of different species of trees, 705.

Ashridge Park, Buckinghamshire, 7548; flower- garden, 6029.

Ashted Park, Surrey, 7588.

Ashton Hall, Lancashire, 7689.

Asiatic fruits deserving cultivation, 8021.

Asimina, polyan. polyg. anonacae, H. tr. N. Amer. which thrive in common soil, and are increased by layers.

Aspalathus, diadel. decan. and leguminoseae, S. tr. and G. tr. peren. C. B. S. which grow freely in sandy loam and peat, and young cuttings root in sand under bell-glasses, care being taken to wipe the glasses frequently to prevent their damping off.

Asparagus, plants, 3855.

Asparagus, hexan. monog. and asphodelaceae, S. G. and F. tr. Eur. and C. B. S. climbers, which grow freely in light loam, or loam and peat, and are increased by dividing at the root, or by cuttings under a hand-glass without bottom heat.

Asparagus officinalis, the garden asparagus, 3856; to force asparagus, 3549; plants, planting, time of beginning to force, temperature, air, water, gathering, succession supplies, 3350. 58; to force in hot-beds, 3559; forcing the roots as they stand in the open ground, 3564.
Asperugo, German mad-wort, petanu, monog. and boraginea, a H. an. of British of common culture.
Asperula, woodruff, tetran. monog. and rubiaceae, a H. per. and A. of Eur. of easy culture.
Asphodel, — see Asphodelus.
Asphodelus, asphodel, hexan. monog. and asphodeles, H. peren. Eur. of common culture.
Asplenium, spleen-wort, crytosteg. filices, and filicinae, S. G. and H. peren. Eur. and S. Amer. ferns which may be cultivated as aspidium.
Association of ideas, its influence on the mind as to the Expression of Sensations, 7171. to 7174.
Asstankina, a seat near Moscow, 262.
Astley, Francis Dukentake, Esq., a British author on gardening, page 1112. A. D. 1709.
Aston Park, Shropshire, 7569.
Astragalus, milk-vetch, diad. decan. and leguminosee, G. and H. peren. and H. an. Eur. As. aff. all of which thrive well in common soil, and are increased by offsets or seeds.
Astrantia, master-wort, petan. dig. and umbellifere, H. peren. Eur. of the easiest culture.
Astrolonia, petan. monog. and epacridae, a G. tr. of easy culture, which thrives best in loam and peat, and young cuttings root readily under a bell-glass in sand.
Athananta, spigol. petan. dig. and umbellifere; H. peren. and H. an. Eur. of easy culture and propagated by seeds.
Athanasia, synen. poly. equal. and corymbifere, G. and H. peren. of easy culture, and cuttings root readily under a hand-glass; the H. an. species require the usual culture.
Atractylis, synen. poly. equal. and cyanocarcophyllum, H. peren. Eur. of common culture, Atractylis tenuis, Atractylis tenuissima, of the usual culture. Requires the usual culture.
Atriplex, orache, polyen. monog. and chenopodae, Eur. of easy culture, and increased by cuttings; and may be increased to the same extent as such.
Atriplex hortensis, the garden orache, 5787.
Atropus, petan. monog. and solanacee, a G. tr. Eur. which grows in light loam, and is readily increased by cuttings, and a H. peren. of easy culture increased by seeds.
Atropus mandragora, the mandrake, 59.— see Mandragora.
Aubletia, polyen. monog. and talicaceae; S. tr. S. Amer. which grow freely in light loam, and well ripened cuttings strike under a bell-glass, if not allowed to dam off; it flowers best when the stem is ringed.
Audrey Hall, Warwickshire, 1571.
Aucuba, monog. tetracarp. and rhamnaceae, a H. tr. Japan, which grows in common soil, and is readily increased by cuttings.
Auley-end, a seat in Essex, 7592.
Augarten, a public recreation ground at Vienna, 205.
Aulax, dioec. tetran. and proteaceae, G. tr. C. B. S. which thrive best in sandy loam with a great many sherds at the bottom of the pot. Cuttings taken off at a joint will root in sand under a hand-glass, care being taken to avoid damps.
Auricula, see Primula.
Austen, Francis, a British author on gardening, page 1099. A. D. 1651.
Austen, Ralph, a British author on gardening, page 1100. A. D. 1653.
Avens, geum avens.
Avicesea, a, dipnog. parent. terebricattaceae, S. tr. E. Ind. which thrive well in light sandy loam; and ripe cuttings root freely in sand under a hand-glass.
Avicennia, 1769; for singing birds, 1761; parrots, 1702.
Avincian, a seat in Hampshire, 7594.
Avicennia, didyn. angios. and myopiricenea, India, a S. tr. soil, loam and peat, and cuttings root in sand under a glass, in moist heat.
Awil-wort, — see Subularia.
Axafrutta, a, monocarp. and chenopodae, H. an. Siberia, common culture.
Ayenia, petan. monog. and rhodacaeae, N. Amer. and India, the G. tr. thrive best in sand and peat, and cuttings are taken off closely the ripened wood, and planted in pots of sand, will root readily in moist heat under a bell-glass; the H. tr. Eur. and Amer. thrive better on sandy loam, and vegetable earth, and are increased from layers or seeds, 659.
Azer, Gerliff, of Ispahan, an encourager of gardeners, 1170.
Azarole, mespusius azarolus.
Azorolus, 261.
B. B. P. Brown’s Prodromus Florae Novae Hollandiae, &c.
Babiana, trian. monog. and irideae, G. peren. C. B. S. usually grown by seeds.
Balsam, Balsam-herb, Balsam-tree, Balsam, from seeds or sandy loam and peat, and are propagated by offsets or seeds.
Balsam, a seat near Northumberland, 7586.
Balsamia, ploughman’s spikenard, synen. polyg. super. and corymbifere, A. and G. tr. which grow in loam and peat, and cuttings root readily in sand under a hand-glass.
Baccheo, the common name of the apricot in Tuscany, corrupted from the original Arabic word, Berco, 4922.
Bado, — his works on gardening, page 1128.
Baccharis, ploughman’s spikenard, synen. polyg. super. and corymbifere, A. and G. tr. which grow in loam and peat, and cuttings root readily in sand under a hand-glass.
Baccheo, the common name of the apricot in Tuscany, corrupted from the original Arabic word, Berco, 4922.
Bactris, hexan. dig. polyenone, a G. tr. peren. and C. B. S. which grow in loam and peat, and cuttings root rapidly under a hand-glass.
Baccharis, synen. polyg. equal. and corymbifere, G. and H. peren. and S. Amer. palms, which thrive in sandy loam, and like other palms, are only to be propagated by seeds.
Baldington House, Gloucestershire, 7565.
Balleria, octan. monog. and myriacaeae, G. tr. N. S. W. which grow in loam and peat, are very hardy, and cuttings of the young wood root readily in sand under a bell-glass.
Banana, the red wood, eanocnuthus colunbarius, — see Coffeoths.
Bailey, W. D. and list of curvilinear hot-houses erected by them, 1587.
Balsamia, synen. polyg. super. corymbifere, a H. an. and to be considered common culture.
Baldwin (of bold, Sax. bold, and winacen, Sax. to overcome; a bold man, a conqueror), Thomas, estate of gardener to the Marquis of Hertford, at Jago, Norfolk, and at Alchester, Worcestershire, one of the first pine growers in England; his work on gardening, page 1114. A. D. 1818.
Ballinalee Castle, a seat in Fifehire, 7555.
Ballinnanoa, a seat in Waterford, 7605.
Ballinlough, a seat in Westmeath, 7602.
Ballochmyley, a seat in Ayrshire, 7647.
Bann, — see Meliss.
Balm of Gilead, — see Dracopehalum and Amyris.
Bannawgan, a seat in Ross-shire, 7647.
Balsam, — see Impatiens.
Balsamina, synen. polyg. access. and corymbifere, H. peren. Ital. of the easiest culture.
Balsamita vulgaris, the costmary, 4192.
Bambusa, bamboo-cane, bamboo, bamboo-cane, hexan. dig. and gramineae, S. tr. India, reeds, which thrive well in a loamy soil, and are readily increased by suckers.
Banna, — see Musa.
Bane-berry (bana, Sax. a murderer, and berry, acte acting.
Banbury, gardens of, 7640.
Banisteria, decan. trig. and malpliogoeae, S. tr. Amcr. and W. Ind. which grow well in sandy loam, and make the root of ripe wood freely under a hand-glass in sand.
Bankeia, tetrad. silic. and scrophulariineae, H. peren. N. Amer. are rather difficult to preserve, and require a shady border of peat earth; or to be planted in pots of the same soil, and kept moist; and H. an. Brit. which grow freely in a sandy soil.
Base-rocket, reseeded lutens.
Basella, pentan. trig. and Chenopodiaceae, S. bien. and am. of garden use.
Baselia alba and rubra, as spinage plants, 4928.
Basil (Basil, a town in Switzerland),—see Ocyum.
Base, (from the Russian bark-bast), cloth of liber, or inner bark, used in gardening, 1560.
Basilia, dodoc. monog. and sapotaceae, S. tr. E. Indies, which propagate freely in light loam, or loam and peat; and ripened cuttings strike under a hand-glass in sand.
Basangnour Hall, Durham, 7584.

Bearberry, arbutus uva-ursi.
Beaudesart, a seat in Staffordshire, 7570.
Beaufort, polyadelph. icosaen. and myrtaceae, G. tr. N. Hol. roll, two thorns peat and one third sandy loam, and cuttings from nearly ripened wood, strike root freely in sand under a bell-glass.
Beaumanor, a seat in Leicestershire, 7573.
Beauvoir, a town in Normandy, a name assumed by Mr. Spencer, and affixed to letters from China, translated from those of the Jesuits, and descriptive of the Count's gardens, 470.
Beaumont, Simon de, a distinguished citizen of Holland in the 17th century, a great encourager of botany and gardening, who had a fine garden at Beverley, 1192. A. D. 1820.
Beaumont Lodge, Berkshire, 7561.
Beaucourt,—his work on gardening, page 1192. A. D. 1788.
Beauty, that property in objects by which they are...
recommended to the power or faculty of taste: the reverse of ugliness; the primary, or most general object of love or admiration. (Jeffrey, in Spectator. But that which gives pleasure to the mind in objects of sense. (M.A. Schmeltner-}

penick, chap. L.)

Though, in the common colloquial acceptance of the term beauty, it is applied only to such objects as delight the senses of vision and hearing; yet, in the strict and literal sense of the word, a fine view, a harmonious concert, the perfume of a flower or the taste of an anana, are each possessed of beauty.

The authors quoted, and also Alison, Stewart, and some of the modern writers, have claimed the subject of beauty in a clear and satisfactory manner, by which it appears that the great error of preceding writers on the subject, consisted in supposing that there was only one kind of beauty; whereas there are many kinds, though some are much more general and universal than others. Nothing but mind can either please or disgust mind; and therefore the beauty that we see in objects depends, as D'Alembert has observed, on what is within ourselves. Man is possessed of the origin of every taste and refined enjoyment naturally; but every one of these, from the lowest sense to the highest, requires cultivation before it becomes capable of conferring much intellectual gratification. Though in the nature of things, there may be an absolute or universal beauty; yet, practically, all beauty may be said to be relative to the state of man in different countries and ages and in different degrees of civilization and refinement. Fashion, therefore, or the prevailing modes of the day, will by the great number of people, always be esteemed the true criterion of beauty.

Beauty of kitchen-garden scenery, 2535; of the flower-garden, 5201; of landscape scenery, 7157.

Beck, D. J. M. his works on gardening, page 1127. A. D. 1818.

Becker, William, Glo. his work on gardening, page 1127. A. D. 1733.

Beckett, the seat of Rev. Lord Barrington, near Farrington, in Gloucestershire, 536.

Beckmannia, trian. dig. and gramineae, a H. an. Eur. a grass of the easiest culture.

Beckmams, John, 75, his writings relative to gardening, page 1124. A. D. 1781.

Beckstall, J. K. his works on gardening, page 1125. A. D. 1795.

Beddington, a seat in Surrey, 7558.

Bedfordshire, gardens and residences of, 7549.

Bed-straw, see Galium. Bed-rock, see Aulis.

Bee-house, see Apiary.

Beech, see Fagus.

Beechwood Park, Hertfordshire, 7544.

Beet, 3731, see Beta.

Beet (Sacca), to boot or help, a term used by gardeners in Scotland for filling up blanks in plantations. To beat up, is with them synonymous with to plant up, or fill up with plants, 8881.

Begonia, montec. polyan. and hydrocharides, S. tr. peren. and bien. S. Amer. succulent plants which grow readily in sandy loam, and cuttings root freely in the same soil.

Bejarias, dodoc. monog. and rhoracaces, a G. tr. Fossils, this best in sandy soil, may be increased by layers and cuttings; the latter planted in sand under a bell-glass in a little peat.

Belch, a seat in Kildare, 7657.

Belchamp, hill, a seat in the county of Durham, 7584.

Belcher, William, his works on gardening, page 1131. A. D. 1755.

Belle-vue, a seat in Hampshire, 7594.

Bell-flower, see Campanula.

Bell (Sagittaria) a viverrine, or, of glass, in one piece; called a receiver among chemists. It is used for covering cuttings of plants, and differs from a hand-glass, in the latter being larger and composed of several pieces glazed in a frame, 1431.

Bellows for fumigation, used in gardening, 1482.

Belmont, a seat in Herefordshire, 7568.

Belmont, a seat in Staffordshire, 7570.

Bellflower, Erem. Brit. near Paris, which before the revolution, belonged to the celebrated Prince de Ligne, 169.

Belvou, Peter, a French writer on gardening, page 1126. A. D. 1553.

Belvidere, a seat in Kent, 5757.

Belvoir Castle, Lincolnshire, 7578.

Belvoir, a seat in Derbez, page 7563.

Belvoir beauty view, Fr., a very common name of country-seats in most parts of the world.

Benoard, Mons. de, author of some papers on gardening, published in the Journals de la Societe du Seine et Oise, during the present century, 185.

Bengal, its circumstances as to gardening, 500.

Bengalure, a royal residence with cultivated gardens, page 7561.

Benham House, Berkshire, 7561.

Benigni, Fortunato, his work on gardening, page 1128. A. D. 1813.

Benjamin, Brett, Ernest bensoin.

Benningsen, General Von, a native of Germany, and general of cavalry in the Russian service; a warm patron of arts and sciences, who had a fine seat and botanic garden near Wilna, which was burnt to the ground and destroyed in the retreat of 1812, 283.

Berberis, see Agrostis.

Bentley Priory, Middsex, 7521.

Bents, bulrushes, see Juncus.

Bertianda, syng. polyg. asul. and cyanocarphe, tr. and bien.

Berberis, barberry, hexan. monog. and berberideis. H. tr. Euer. and Amer. of robust growth and hardy, propagated by suckers and seeds.

Berberis vulgaris, the common barberry, 4693.

Beuze (cradle, arch, Fr.), an arbor or bower, formed in horticulture and arboretica as a place for recesses, 256.

Berckheya, syny. polyg. frust. G. tr. and bien.

B. C. S. which grow freely in low and peat, and root readily in common earth under a hand-glass.

Berger, Ch. Glo., his works on gardening, page 1126. A. D. 1705.

Bergeron, —, his work on gardening, page 1130. A. D. 1780.

Berkshire, gardens and residences of, 7560.

Bernstein, J. Glo., his work on gardening, page 1125. A. D. 1783.

Beroet, a seat of the Emir Facadine, near Jerusalem, in the 17th century, 457.

Berries, grown in horticulture, as edible fruits, 4295.

Berry-raking, see Juncus.

Berrington, a seat in Herefordshire, 7568.

Berry-bearing alder, rhamnus frangula.

 Bertie, see Bertie.

Berthelot, —, his works on gardening, page 1120. A. D. 1860.

Bertrand, Francis, his works on gardening, page 1118. A. D. 1727.

Bertrand, Mons. of Bruges, his villa, 122.

Bertuch, M. his work on gardening, page 1127. A. D. 1721.

Bertwick, gardens of, 7620.

Besca (old Latin), a spade or shovel.

Besl. estys, Besleri hortus cytstettinos, etc.

Besler, A. Angul, or angul, a spore carphe, S. tr. W. Ind. handsome plants of easy culture in rich light soil. Cuttings strike freely in rotten tan, without any protection.

Beson —, a French writer on gardening, page 1116. A. D. 1705.

Besom, different kinds of, used in gardening, 132.

Beta, beet, pent. dig. and chenopodaceae, a G. bien.

Beta cilia, the white beet, a spinaceous plant, 3779.

It is from the roots of this last species that the French and Germans obtained sugar with so much less labor during the late war. The follow-

ing was the ordinary process: — Reduce the roots to a pulp, by pressing them between two rough cylinders with a weight on them, and press out the liquor it contains; boil this liquor, precipitate the saccharine matter by quick-lique; pour off the liquor; add to the residuum a solution of sulphuric acid, and boil again; the lime uniting with the acid, is got rid of by straining; and the
liquor may then be gently evaporated, or left to granulate slowly, after which it is ready for undergoing the common process of refinishing raw sugars.

Beta maritima, a native plant which may be used for an escula, 402; 7564.

Beta vulgaris, the common red beet, 3731.

Betonica, betony, didyn. gymn. and labiate, H. peren. Eur. of common culture.

Betonica officinalis, a plant, 4319.

Betony, — see Betonica.

Betula, birch, monoe. polyan. and amantaceae, H. tr. of easy culture; the American sorts prefer boggy, sandy, and moist places, are propagated by seeds or layers, and some curious sorts by grafting or budding.

Biloba, alchem. and other species cultivated as timber-trees, 7108, to 7111.

Bevel, or bevel-square, an instrument made use of by carpenters and masons, and also in gardening for cutting the edges of soil, 1104.

Rib. Bank., bibliotheca banksiana.

Bickham, George, a British writer on gardening, page 1104. A. D. 1750.

Bielton, a seat in Devonshire, 7600.

Bidens, syngen. polyg. equal. and courymifolse, a s. an. H. peren. and H. an. E. Ind. and S. Amer. This is a genus of biennials, which may be treated as tender and half-hardy annuals; they prefer a moist situation and light soil. The perennials may be kept in pots in similar soil, and propagated by dividing them when well grown.

Biedt, M.,—his writings on gardening, page 1118. A. D. 1750.

Biennials and biennials, such as of two years' duration in their natural circumstances; but by culture, and especially by pinching off the flowers as they appear, many of these may be rendered triennial or perennial in duration. Many exotics, which are annuals and biennials in their native countries, are perennials in our stoves.

Biennials, hardy, 6504.

Biennials, frame, 6563.

Biennials, green-house, 6630.

Biennials, stove, 6638.

Bigonia, trumpet-vetch, didyn. angios. and big-noises, H. S. and G. tr. S. Amer. and China, some are climbers, and all grow well in peat and loam, and young shoots root readily, either in mould or sand, under a hand-glass in heat. The H. tr. are climbers, and grow well in common soil, and are increased by cuttings from the young wood or roots.

Biltmore House, Yorkshire, 7582.

Bill, an edge-tool, at the end of a stake or handle; if short, it is called a hand-bill, and when long, a hand-spade, 7560.

Billardiera, apple-berry, peauton. monog. and pittoresque, G. tr. Austral. climbers, which thrive well in loam and peat, and cuttings root readily in sand and a bell-glass.

Billet (billet, Fr.), a tree or log of wood, cut up for fuel; billet-wood.

Biscutella, buckler-mustard, tetrad. silig. and crucifere, a F. tr. and H. peren. and an. Eur. of common culture.

Bishop's Court, a seat in Kildare, 7567.

Bishop's weed, — see Ammi.

Bilton House, the seat of Addison, in Warwickshire, 7501.

Binde, — see Convulvulus.

Binannium (Lot.), a pond or stew for the keeping and feeding of fish.

Birch, of see Betula.

Bird-pepper, — see Capsicum.

Birds, or feathered enemies of gardens, 2229; how to destroy, 5390.

Birn's eye, primula farinosa.

Bird's foot, — see Ornithopus.

Birdsfoot-trevail, — see Lotus.

Birdsfoot-trefoil, — see Lotus. 14582.

Bird-silk, — see Aristolochia.

Bitter-sweet, solanum dulcamara.

Bitter-vetch, — see Oregoneae.

Bixa, anota, polyan. monog. and tabilea, a S. tr. W. Ind. which grows to a large plant before it flowers, and therefore cuttings should be taken from flowering plants, in order that they may flower soon: they root freely under a hand-glass in sand, and the plants grow well in loam and peat.

Blackberry; in England, the berries of the Bramble are so named; and in Scotland, those of the black current.

Black bryony, — see Tamus.

Black saltwort, glau-marinia.

Black sapling, gymn. and papa-vera, 7109.

Blackmore Park, Worcester, 7566.

Blackwell, Elizabeth, widow of Dr. Blackwell, who died in Sweden; author of a curious herbal, containing 304 species of the useful plants.

Bladder-nut, — see Staphylea.

Bladder-summer, — see Colutea.

Blade (blad.), a leaf.

Blaria, tetran. monog. and ericaceae, G. tr. C. S. which thrive only in sandy peat, and young cuttings will root in sand under a bell-glass, or in a close cell in a shady situation.

Blair Adam, a seat in Kinross-shire, 7694.

Blair Drummond, the seat of the late Lord Kaimes, and now of Mr. Home Drummond, in Perthshire, 7694.

Blair House, or Blair Athol, a seat of the Duke of Atholl, in Perthshire, 7560.

Blazé George, in Gloucestershire, 7564.

Blake, Stephen, a British writer on gardening, page 1101. A. D. 1664.

Blakea, dodec. monog. and melastomaceae, a S. tr. Jamaic. and south Africa, which thrives well in peat and loam, and requires a good deal of water; cuttings require to be quite ripe, otherwise they rot; planted in sand in moist heat under a hand-glass, they root freely.

Blakie, Thomas, Esq. of Beechwood, near Edinburgh, C. M. H. S., 170.

Blanchard distempering, a process for depriving plants of part of their bitter qualities, 2156.

Blanching-pots, 1427.

Blandshardia, hexan. monog. and hemerocallidaceae, G. peren. and S. W. which grow in sandy loam and peat, and are propagated by suckers or seeds.

Blarney Castle, in Ireland, 568.

Blast, plants, and especially the cereal grasses, are said to thrive well when the bluest or cans are lank and thin, —see Vegetable Pathology.

Blatta, the black beetle, or cock-roach, 2259.

Blattaria, anhydro. and florecaracaceae, a S. peren. W. Ind. which grows well in rich light soil, and cuttings root freely under a hand-glass in heat.

Blaehum, cryptog. filices. and filiceae, G. and H. peren. C. S. Eur. and N. Amer. ferns, which grow in loam and peat, and are increased by divided at the root or seeds.

Blended Hall, Kent, 1687.

Blenheim, a seat in Oxfordshire, 7520.

Blessington gardens, situated in the county of Dublin, and belonging to Mr. Howard, 7560.

Blletia, gynan. monan. and orchideae, S. peren. China and W. Ind. which grow well in sandy loam and peat, and are readily propagated by dividing at the root; or seed.

Bllicking Hall, Norfolk, 7554.

Blighia, akee-tree. octan. monog. and sapindoceae, a S. tr. 7353.

Blight, a common term for injuries received by the vegetable kingdom when in a state of growth, which cannot be referred to any obvious or certain cause, and coming suddenly is said to give them the appearance of being blighted or blasted, — see Vegetable Pathology.

Bilton or Blythe, Walter, A. D. a British writer on gardening, page 1101. A. D. 1649.

Blithfield Park, Staffordshire, 7570.

Blit, an ancient synonym for the beet, beta.

Blitum, strawberry-bite, monan. dig. and chenopodio. monoec. one of the easiest culture.

Bobart, Jacob, a British author on gardening, page 1101. A. D. 1684.

Boboli gardens, at Florence, 83.

Bocconia, tree-celandine, dodec. monog. and papa-vera, 2029.

Bocconia, in Ind. Ind., which grows well in sandy loam, and ripens seeds plentifully; and a H. peren. China, which grows in rich soil, and is propagated by dividing the roots.

Boccieri, — his work on gardening, page 1137; A. D. 1615.

Bodach, a seat in Montgomeryshire, 7611.

Bodorgan, a seat in Anglesey, 7603.

Boehmeria, monoe. itan. and urticaceae, G. tr. Canar, which thrives well in loam and peat, and cuttings root freely in the same kind of soil.
under a hand-glass. The H. perren. Virginia, grows in peat soil, and is propagated by dividing the root.

Boethavalia, hog-weed, dian, monoy, and nyctaginaceae, are hardy perennials. Indies, which thrive well in rich loam, and cuttings root readily.

Boettiger, C. A., his works, page 1127. A. D. 1817. Bierling, see Bradwell.

Boltonia, syngen, polyg. super, and corymbiferaceae, are in former culture, 7524.

Bombax, silk-cotton tree, monad. polyan. and malvaceae, S. tr. E. Ind. and S. Amer. which grow freely in loamy soil, and cuttings, not too ripe, taken off at a joint, will root freely under a hand-glass in heat.

Bonchurch Cottage, Isle of Wight, 759.

Booth's Borage, Borago officinalis, is a British author on gardening, page 1099. A. D. 1629.

Bonville, Charles, his work on gardening, page 1118. A. D. 1703.

Bonville, Eugene, angios, and myoporineae, a S. tr. W. Ind. which thrives in peat and loam, and cuttings root readily in heat, under a hand-glass.

Borbonia, diadel. decan. and leguminosseae, G. tr. C. B. S. which grow in loam and peat, and young cuttings strike readily under a bell-glass in sand.

Borcher, Michael Jean, Comte de, his works on gardening, page 1128. A. D. 1790.

Border (bordure, Fr.), the edge, fringe, or margin of any thing, or any thing when distinguished by a line of demarcation, by ornament, or otherwise, from the main piece or plot.

Border-flowers, herbaceous plants of hardy constitution and easy culture, well adapted for ornamenting borders. In floriculture they are classed under distinct heads, viz. as perennial, 649; bulbs, 6500; biennials, 6504; hardy annuals, 6506; half hardy annuals, 6521; for particular purposes, 6515; for concealing upright deformities, 6516; horizontal deformities, 6517; which will grow under shade and in blue trees, 6518; for ornamenting pieces of water, 6519; rocks, 6524; with evergreen leaves for winter display, 6527; for edging to beds or borders, 6528; highly odoriferous, 6530; for deep shade, 6538; and musces, 6534; alpines, 6537; common showy sorts for a small garden, 6538.

Borneo, for fruit trees, 2414.

Borders for gardening are of general use in horticulture and floriculture, as accompaniments to walks, and walls or other fences. The former are chiefly as ornamental compartiments, and the latter partly ornamental, but chiefly for the culture of fruit-trees, and the more delicate herbaceous sculent. The width of borders that are seen, and for walks, is generally governed by that of the walk; but they are esteemed handsomer when broader rather than narrower; wall or fence borders, according to the improved ideas, never be less than the height of one-half the wall or fence; since the roots of a tree require as much room to extend themselves as the shoots. For the culture of fruit-tree borders in kitchen-gardens, see 2484; and in flower-gardens, 6111. to 6118.

Boscole (boreal cole, norther cole or cale), see Brasicae.

Borghese, villa of, at Rome, 84.

Borneafolia, a French writer on gardening, page 1110. A. D. 1660.

Cactic, a kind of cosmopolitan, and corymbifereae, a S. tr. and S. an. C.H.S. and Amer. succulents, which grow in sandy loam and brick-rush, and are propagated by cuttings; the H. peren. are cuttings of eucalycium.

Cachyris, pentan. dig. and umbellifereae, H. peren. Eur. of common culture, and propagated by seeds.

Cactus, ixsaz, monog. and cactaceae, S. tr. Ind. and Amer. and G. tr. succulents of easy culture.

Cactus opuntia, the Indian fig, 5966.

Cactacium, decan. monog. and onagaram, a S. tr. Guiana, which grows well in loam and peat, and cuttings freely in sand under a hand-glass.

Cahet, Charles Louis, his works on gardening, page 1130. A. D. 1801.

Caldecote-Faux, Antoine Alexis, his works on gardening, page 1121. A. D. 1806.

Cadias, decan. monog. and leguminoseae, a S. tr. Arabia, which prefers a light soil, and cuttings root in sand under a hand-glass and plunged in heat.

Caldeland, a seat in Hampshire, 7594.

Caenwood, a seat in Middlesex, 7521.

Caernarvonshire, gardens and residences of, 7504.

Calapalina, decan. monog. and leguminoseae, S. tr. E. and W. Ind. prickly branched, which thrive well in loam and peat, and cuttings sometimes succeed, but not in a growing state, but not too young, and plunged in a pot of sand under a hand-glass, in moist heat.

Calanthe, hexan. and asphodelaceae, a G. peren.

N. W. S. which grows in loam and peat, and is increased by dividing at the root or by seeds.

Cesalpinia, syngon. polygon. and corymbifereae, a S. peren. E. Ind. requiring a rich, loamy soil, and cuttings root freely.

Cathness, gardens of, 7644.

Cakile, tetrad. sile, and cruciferaceae, a H. peren. and
INDEX.

an. Eur; the first best grown in pots, and the other of common culture, and both increased by seeds.

Calathea-tree, — see Crecentia.

Caladium, monan, and orchideae, a G. peren. N. S. W. which may be grown in loam and peat, and increased by division at the root.

Caladenia, trian, and minima, H. peren. Eur. grasses of the easiest culture.

Calamintha, — see Calaminthum.

Calamus, hexan, monog. and palmeae, S. tr. E. Ind. palms, which thrive best in sandy loam, and a warm, moist atmosphere, and are propagated by seed.

Calendula, octan. tetrag. and sempervivae, D. S. tr. As. and Afr. succulents which thrive well in sandy loam, but require bottom heat to make them flower. The leaves placed on a pot of moist sand, the tan, will shoot out young plants from the notches of the margin.93 (Sweet.)

Calathian violet, gentiana pneumonanthe.

Calceolaria, slipper-wort, dias. monog. and scrophularineae, G. peren. and an. Peru and Falkland islands, of easy culture, and propagated by seeds.

Calceolus, gardening of, 500.

Calcedonia, monog. and scrophularineae, a S. an. New Spain, of common culture.

Calder House, Midlothian, 7618.

Calophyllum, — see Calophyllum.

Calystegia, — see Calystegia.

Camellia, — see Camellia.

Campanula, bell-flower, monog. and campalineae, G. tr. peren. bien and an. H. peren. and an. Eur. As. Afr. and Am. of common culture, after increased by seeds, dividing at the root, or by cuttings.

Campanula rapunculosa, the rampion, 3941; campanula sicula, 946.

Camphor tree, laurus camphora.

Campylosoma, tetran. monog. and verbenaceae, S. and G. tr. E. Ind. and Ameer, which grow best in loam and peat, and ripened from strike root in sand under a glass-haus in heat.

Camilla, dodec. dig. and cunicnaceae, a G. tr. N. S. W. which thrives in loam and peat, and cuttings of ripe wood root readily in sand under a glass.-glass.

Calligonum, dodr. tetrag. and polygonaceae, a H. tr. Caspian Sea, which may be grown in loam and peat, and propagated by layers.

Callirhoe, trian. monog. and commelinaceae, a S. peren. W. Ind. a creeper of easy culture.

Callitris, leguminoseae, G. tr. N. Holl, which grow fast and flour quite freely in loam and peat, and cuttings planted in sand under a glass-haus are usually increased by seeds, layers, or cuttings of the young shoots planted in sand under a glass-haus.

Calodendrum, pentan. monog. and pittosporaceae, a G. tr. W. Ind. and Ameer, is of great beauty. It grows in loam and peat, and cuttings of ripe wood root readily in sand under a glass-haus.

Calodinium, monog. polygon. and aridoideae, S. tr. and peren. Ind. and Ameer, most of which grow freely in water, or in rich soil in a moist heat; they are propagated by tubers of the root.

Catonec, — see Calotropis.

1177

Calophyllum, polyan. monog. and guttiferaeae, S. tr. Ind. which grow well in light loam, and cuttings of ripened wood strike freely in sand, under a hand-glass in moist heat.

Calopogon, monog. and orchideae, a F. peren. N. Amer. which grows in peat, and is increased by dividing at the root.

Calothamnus, monan. isom. and myrtaceae, G. tr. N. Holl. which thrive in loam and peat, and cuttings root in sand under a bell-glass.

Calotropis, pentan. dig. and asclepiadaceae, S. tr. N. Amer. which grow in light loam, young cuttings root freely under a hand-glass in a pot of sand, care being taken that they do not get mouldy.

Calvors, — see Tribulus.

Calvert, Etienne, his works on gardening, page 1121, A. D. 1821.

Calvert and Co., their work on gardening, page 1129, A. D. 1821.

Calycanthus, isom. polyg. and rosaceae, H. tr. N. Amer. which grow well in loam and peat, and root by layers in the same soil.

Calyx, gynan. monog. and orchideae, a H. peren. M. Amer. which grows best in peat, or in sandy loam and peat, and is increased by offsets from the bulbs or by seeds.

Calyptranthes, isom, monog. and myrtaceae, S. peren. W. Ind. which grows in loam and peat; and though cuttings do not strike freely, ripened once sometimes root under a hand-glass.

Calyxteginia, handb. pentan. monog. and convolvulaceae, H. peren. Eur. and Amer. of common culture.

Cam, Brit. Camden's Britannia, an antiquarian work.

Cambridge botanic garden, 7551.

Camden Park, in Wexford, 7555.

Cambria, monog. and aurentea, G. tr. chinia, a plant of beauty, freely propagated at a glass-house. Under glass, H. peren. Callendula officinalis, the common pot marigold, 4125.

Cella, pentan. monog. and aroidae, a G. H. peren. Eur. and C.B.S. the first an aquatic, and the other a marsh plant of easy culture. C. ethiopia also will grow well in the green-house soil.

Callander, a seat in Stirlingshire, 7631.

Callicarpa, tetran. monog. and verbenaceae, S. and G. tr. E. Ind. and Ameer, which grow best in loam and peat, and ripened from strike root in sand under a glass-haus in heat.

Callicoma, dodec. dig. and cunicnaceae, a G. tr. N. S. W. which thrives in loam and peat, and cuttings of ripe wood root readily in sand under a glass-haus.

Canary-grass, — see Phalaris.

Candeleberry-myrtce, my rtica gale.

Canthium, monog. and cannabaceae, G. tr. fluimena cretensis.

Candytuft, — see Iberis.

Canella, dodec. monog. and meliaceae, a S. tr. W. Ind. and Ameer. is of hardy nature; and cuttings of large old wood, with all the leaves taken off at a joint, in sand, in a moist heat, strike, though with diffi-

Canna, Indian shot, monan. monog. and cannaceae, S. peren. Ind. and S. Amer, ready or marsh plants of easy culture, and propagated by seeds or dividing the root.

Cannabis, hemp, diece. pentan. and urticaceae, a H. an. India, of easy culture.

Canon House, Sussex, 7531.

Canons, — see Whitsone, Middlesx, 7590.

Cantaeula melon, — see Cucumis.

Canterbury bell, campanula medium.

Cantu, faste gardens at, 7531.

Cape a seat in Inconsquere-shire, 7648.

Cape of Good Hope, gardening of, 509.

Cape jasmine, gardenia flora.

Caper-bush, — see Capparisa.
Cavaliera (Ital.), a manège, or place for practising horsemanship.

Cavan, county of, as to gardening, 7676.

Carniolae, to artificially propagate, his works on gardening, page 1131. A. D. 1787.

Cave, Castle, Yorkshire, 7582.

Caversham, a seat near Reading, 7561.

Cayenne, and its decorations, 1814.

Cayenne, gardening of, 505.

Ceylan, — de, his works on gardening, page 1121. A. D. 1806.

Cecropia, pentan. monog. and rhamnaceae, S. tr. and G. tr. Amer. and W. Ind. which grow in loam and peat, and cuttings root freely in sand under a hand-glass. There is a peculiar habit in common soil, and are readily raised from seeds or layers.

Cecropia, snake-wood, dioc. dian. and urticae, a S. an. which Proposes a loamy soil, and large cuttings planted in sand under a hand-glass will strike root.

Cedars, Cephalus lusitanica.

Cedar of Lebanon, — see Pinus.

Cederholm, Baron Carl Wilhelm, his works on gardening, page 1130. A. D. 1740.

Cedrela, pentan. monog. and medicaeae, a S. tr. W. Ind. which grows well in loam and peat, and cuttings root under a hand-glass in sand.

Celanidium, — see Chelidonium.

Cellis, diety. angios and solanea; S. an. F. bignoniacea, and H. an. Ind. and E. Ind. of common culture.

Celtis, nettle-tree, polyg. monoe. and amaranthaceae, S. tr. and H. tr. Eur. and Amer. which require only common soil and culture, and are increased by seeds or layers, or by cuttings.

Cenchrus, trian. monog. and gramineae, a S. tr. and H. an. India; grasses of the easiest culture. 

Cenia, syngen. polyg. super. and corymbiferae, H. an. C. B. S. of common culture.

Centauraea, benedictae, the blessed thistle, 4250.

Centaurea, see C. Cicuti.

Centunculus, bastard pimpernel, tetran. monog. and primulaceae, a H. an. Brit. of common culture.

Cephalea, pentan. monog. and rubieaeae, S. tr. Jam. and Afric. which thrive in loam and peat, and cuttings roots freely under a hand-glass in sand.

Cephalanthus, button-wood, tetran. monog. and rubieaeae, a H. tr. N. Amer. which grows best in loam and peat, and is propagated by layers or ripened cuttings.

Cephalophora, syngen. polyg. equal. and corymbiferae, a F. peren. Chilis. which grows in sand and peat, and young cuttings root readily under a hand-glass.

Ceratocephala, monoe. monan. and chenopodaceae of H. an. Taranty, of common culture.

Ceratonia, carob-tree, polyg. dience. and legumineaeae, a G. tr. and W. Ind. which grows well in loam and peat, and ripened cuttings root in sand under a hand-glass.

Ceratophyllum, hornwort, monoe. polyan. and piaeiaceae, H. peren. Brit. aquatics of easy culture, and increased by seeds.

Ceresa, pentan. monog. and apoeneaeae, a S. tr. S. America, which grows well in loam and peat, and ripened cuttings root readily in sand under a hand-glass in moist heat.

Cerises, Judas-tree, decan. monog. and leguminoseae, H. tr. and W. Ind. which grows well in common soil, and are raised from seeds or layers.

Cerinthia, honey-wort, pentan. monog. and borageaeae, a H. tr. and an. Eur. of common culture.

Cestrum, pentan. monog. and S. and solanea, G. tr. E. and W. Ind. which grow well in loam and peat, and cuttings root in sand under a hand-glass.

Ceylon, gardening of, 501.

Chaddesdon, a seat in Derbyshire, 7574.

Charophyllum, chervil, pentan. dig. and umbel- liferaceae, a H. peren. and an. Eur. and N. Amer. of the easiest culture.

Chalfont House, Buckinghamshire, 7546.

Chamaecereus, see hexan. and pahenche, a S. tr.

Caracas, which grows in sandy loam, and a strong moist heat and is propagated by seeds.

Champops, polyg. dience. and palmeaeae, S. tr. Eur. and N. Amer., palms requiring the same treatment as chamaecereus.

Chambres, Sir William, as an author on gardening, page 1105. A. D. 1757.

Chambray, Marquis de, his works on gardening, page 1118. A. D. 1763.

Chamomile, — see Anthemis.

Chamomile, Symphonon, a French writer on gardening, page 1115. A. D. 1583.

Champs Elysées, a public garden at Paris, 163.

Chapel Allerton, formerly the seat of R. A. Salisbury, Esq., situated near Leeds, 7561.

Chapital, the Count of, a distinguished French chemist and philosopher, as a gardening author, page 1120. A. D. 1801.

Chapitallia, pea, pea-tree and corymbiferae, a H. peren. N. Amer. best cultivated in loam and peat in pots.

Chara, monoe. monan. and naiadae, H. Brit. aquatics of easy culture.

Charcoal, proportion in which it is afforded by different trees, 410.

Charlestown Park, a seat in the King's County, 7563.

Charlestown, a seat in Wicklow, 7654.

Charlottburg, a royal residence near Berlin, 206.

Charlton House, Kent, 1724.

Chariton Park, Wilthshire, 7567.

Charpentier de Coussigny, his works on gardening, page 1116. A. D. 1790.

Charring wood, method of, 6962.

Chartreuse, les, Rev. Péres de, their work on gardening, page 1118. A. D. 1767.

Chartreuse, a seat at Paris, 7564.

Chartularies, deeds of tenure of the ancient religious houses.

Cheshir, —, his works on gardening, page 1119. A. D. 1759.

Chaste-tree, — see Vitex.

Chataignierges, le Steur de, a French writer on gardening, page 1116. A. D. 1790.

Chatsworth, a seat in Derbyshire, 7563.

Chawstick, goutainia domingensis.

Cheese-remitt, galium verum.

Chelanthium, flaminia, silicaceae, G. and H. peren. As. and Amer. ferns which grow in loam and peat, and require to be kept in a moist shaded situation.

Cheiranthus, wall-flower, tetrad. silic. and cruci- feræe, G. and H. tr. and peren. Eur. and As. under-shrubs and evergreen herbs, of easy culture in light soil, and propagated by seeds or cuttings.

Chelidonium, celandine, polyan. monog. and papa- voraceae, H. peren. Eur. of the easiest culture.

Chelone, dragonies, adonideaeae, H. peren. N. Amer. elegant plants which grow in loam and peat, and are propagated by cuttings or by dividing the root.

Chelsy Farm, Berkshire, 7561.

Cheltenham, a garden at, 7564.

Chemincreux (hollow way), a suburban village at Paris, 7579.

Chensmel, platanus orientalis.

Chenolea, pentan. monog. and chenopodeae, a G. tr. C. B. S. which grows in rich light soil, and cuttings root readily under a hand-glass.

Chenopodium, goose-foot, pentan. dig. and cheno- podaceae, G. peren. and H. peren. and an. Eur. and Amer. of the easiest culture.

Chenopodium bonus-henricus, 2091.

Chenopodium urbicum and album, 4200.

Cherifia, decan. trig. and caryophyllaceae, H. peren. 1545. a rock-work plant which grows in loam and peat, and is increased by dividing at the root.
Chernes, a genus of plant-louse, nearly allied to aphids, and generally confounded with the aphid, C. 2043.

Chercherian, — B. — his works on gardening, page 1121. A. D. 1808.

Cherry — see Prunus.

Cherry-house, 1754. its culture, 3117.

Cherry-pepper. — see Capsicum.

Chervil. — see Chimaphila.

Cheshire, gardens and residences of, 7590. C. corymbifera, the French author on gardening, page 1116. A. D. 1654.

Chesnel, Marquis de, his works on gardening, page 1122. A. D. 1820.

Chessy, see Cestanea.

Chevenering, a seat in Kent, 7538.

Chicken, see Astelia.

Chillingham Castle, Northumberland, 7586.

Chimaphila, decan. monog. and erieea, H. tr. N. Amer. rather difficult to preserve; they grow best in a bed of peat, and seldom transplanted.

Chimampan, or floating gardens of Mexico, 491.

Chicorea, snow-berry, pentan. monog. and rubiaceae, a S. tr. Jam. which thrives well in loam and peat, and cuttings root freely in sand under a hand-glass.

Chionanthus, fringe-tree, dian. monog. and oleinae, H. N. Amer. of great beauty; they grow in good loamy soil, and are increased by seeds or grafting on the common ash.

Chippa Castle, Northumberland, 7586.

Chippewa Falls, Wisconsin, 3117.

Chironia, pentan. monog. and gentianae, G. tr. C. B. S. which grow in peat with a little loam, and young cuttings root under hand-glasses in the same soil.

Chiswick House, Middlesex, 7521.

Chloro, yellow wort, octan. monog. and gentianae, G. tr. of common culture.

Chloranthus, chelran, tetran. monog. and loran-thaceae a G. tr. China, which may be treated as cheloneles.

Chlorophorum, bexan. monog. and asphodelae, a G. and S. peren. Aft. grow in loam and peat, and are increased by dividing at the root, or by seeds.

Chromep-nut, see Theobroma.

Cholmondeley Hall, Cheshire, 7590.

Chomel, Noel, a French author on gardening, page 1116. A. D. 1777.

Chomelia, tetran. monog. and rubiaceae, a S. tr. W. Ind. which grows in loam and peat, and cuttings root readily in sand under a hand-glass in the same soil.

Chondrilla, syngon. polyg. equal. and eichoraceae, a H. peren. France, which grows best in peat soil, and is increased by seeds or dividing at the root.

Chorizema, decan. monog. and leguminoseae, G. tr. N. Hol. which grows in sandy loam and peat, and produces seed in abundance.

Chorizomerum, tetran. monog. and loran-thaceae, a H. an. of common culture.

Christ, J. I., his works on gardening, page 1127. A. D. 1800.

Christ's thorn, zizyphus palmaris.

Christmas rose, — see Helborous.

Chrysanthemum, syngon. polyg. frutian. and corymbifereae, a S. an. W. Ind. of common culture.

Chrysanthemum, syngon. polyg. super. and corymbifereae, G. tr. and H. an. and peper, which grow in common garden-soil, and are increased by dividing the root, or by cuttings, or seeds.

Chrysanthemum leucanthemum, 4516.

Chrysanthemum integrum, — see Anthismus.

Chrysodalanus, cocoa-plum, icac. monog. and rosea, a S. e. and G. tr. W. Ind. and Georgia, which grow in sandy loam, and large cuttings strike off freely, with their leaves incurved, and planted thinly in a pot of sand, under a hand-glass, will strike root.

Chrysanthemum periclymenum, sympygot. polyg. equal. and corymbifereae, G. tr. C. B. S. and Eur. which thrive in loam and peat, and cuttings root readily under a hand-glass.

Chrysanthemum star-apple, pentan. monog. and sapoten, a S. tr. W. Ind. which thrive in sandy loam, and cuttings of ripened shoots root in sand under a hand-glass, with a strong moist heat.

Chrysophyllum, golden saxifrage, decan. dig. and saxifragese, H. peren. Eur. and Amer. which grow in shady moist places, and may be treated as marsh plants.

Chrysirus, triang. dig. and gramineae, a H. an. of common culture.

Chulan. — see Chloranthus.

Cicely, — see Scandix.

Cicer, chick-pea, diadel. decaan. and leguminoseae, a H. an. of the easiers culture.

Cichorium, succory, syngon. polyg. equal. and cichoraceae, a F. bien. H. peren. and H. tr. Eur. A. D. 1654. which are easily increased. C. cendiva, the garden endive, 3976. C. intibus, succory, 3985.

Cienta, cow-bane, pentag. dig. and umbellifereae, F. tr. and Amer. which grow best in marshy places, and are increased by seeds.

Cincentifuga, bugwort, pooyan. pentag. and ranunculaceae, H. peren. Eur. and Amer. of common culture.

Ciporta, pentan. monog. and rubiaceae, S. G. H. tr. tr. peren. and Amer. which grow freely in loam and peat, and cuttings root under a hand-glass.

Climberia, syngon. polyg. super. and corymbifereae, S. G. and H. tr. and peren. Eur. and C. B. S. plants of easy culture, and propagated by cuttings, division, or seeds.

Cion, — see Cynon.

Clipping, the winter's nightshade, dian. monog. and onagrarieae, H. peren. Brit. creepers, which prefer moist shady situations, and grow in any soil.

Clissampeleo, dioec. monad. and menispermaceae, a G. tr. and Amer. elorida, which grow freely in loam and peat, and cuttings root under a hand-glass.

Clissampeleo, monog. and vitaceae, S. G. and H. tr. Amer. and Ind. of easy culture in peat and loam, or in garden-earth, and readily propagated by cuttings; the S. and G. sorts in a moist heat, and the others in the shade under a hand-glass.

Citus, rock-rose, polyg. monan. and cistnaeae, G. tr. and H. tr. Eur. and Amer. shrubs, which grow in common soil, or loam and peat, and may be increased by layers, or young cuttings taken off at a joint, and planted under a hand-glass, which is frequently produced.

Citharexylum, fiddle-wood, didyn. angios. and verbenaceae, S. tr. W. Ind. which grow freely in loam and peat, and cuttings root in sand under a hand-glass.

Citizens' villas, 7285 ; management of, 7430.

Citrus, orange-treec, polyd. polyan. and aurantiaceae, Amer., see Chaussea, — see 4979.

Citrus acida, the lime, 4589.

Citrus aurantium, the orange, 4884.

Citrus decumana, the shaddock, 7602.

Citrus limon, the lemon and citron, 4896, 4897.

Citrus tribe, their propagation and culture, 7505. to 7691.

Clackmannanshire, gardens of, 7633.

Cladium, trian. monog. and cyperaceae, H. peren. Eng. a grass of the easiest culture.

Clavine, de, open railways or barriers, 533. Land, or rape cuttings grown, his work on gardening, page 1128. A.D. 1726.

Clandon Place, a seat in Surrey, 7529.

Clare, county of, as to gardening, 7669.

Clare Hall, a seat in the county of Dublin, 7563.

Chereston, a seat in Surrey, 7528.

Clary, — see Salvia.

Claytonia, gardens of, 7542.

Claytonia, pentan. monog. and portulaceae, H. peren. and Amer. and N. Silesia, of the easiest culture.

Clasporium perfoliata, as a spinach plant, 4527.

Clear Well, a seat in Gloucestershire, 7565.

Clearing-nut, strychnos potatorum.

Clematis, virgin's bower, polyan. polyg. and ranunculaceae, S. and G. tr. climbers, which grow in light, rich soil, and young cuttings strike readily under a hand-glass in heat. The C. species grow in any soil, and are increased by layers, dividing at the root or seeds.

Clementa, y Robin, Don Simon de Roax, his work on gardening, page 1131. A.D. 1907.

Clermont, a seat in Lowth, 7664.

Clerodendrum, didyn. angios. and verbenaceae, S. and G. tr. Ind. and China, soil half-loam, a quarter rotten dung, and a quarter peat; they require a large pot to flower freely, and young cuttings root readily under a hand-glass.
Cour, William, Esq., his work on fruit-trees, page 1131. A. D. 1817.

Craw, craggy Hall, a seat near Edinburgh, 390.

Crail, Crailing, Craighie, Craiggie, Crambe, Cranford, Cow-wheat, Cowel, Coventry, Crown, crowfoot, lychnis foscusculi.

Crawford's House, Roxburghshire, 7621.

Cramb, crumble, tetrad. silic. and cruciferise, G. tr. and peren. and an. Eur and Amer, which thrive in rich, light soil, and are increased by seed or dividing the root.

Crake, see Caper, capparideae, S. tr. W. Ind. and Afr. which grow in low, peat, and rotten dung, and are increased by cuttings in sand, under a hand-glass.

Cran, cranberry, pentan. monoce. and eucribtaeae, F. and H. an. C. B. S. succulents of easy culture.

Cranberry, see Cranberry-peat, dodec. monoce. and capparideae, S. tr. W. Ind. and Afr. which grow in low, peat, and rotten dung, and are increased by cuttings in sand, under a hand-glass.

Crane, see Lepidium, for the sake of the wild mustard; 3898.

Crane, John Andrews, his works on gardening, page 1124. A. D. 1766.

Cranberry, see Cynoglossum. Cranberry, H. peren. and an. and H. an. C. B. S. succulents of easy culture.

Crane, see Geranium.

Cranford Bridge, Northamptonshire, 7590.

Cranford Lodge, Middlesex, 7590.

Crane, see Lepidium, for the sake of the wild mustard; 3898.

Crepis, syneg. polyg. augul. and cichoraceae, H. tr. peren. bien. and an. Eur. of easy culture.

Crecessia, capparideae, didec. angios. and solanae, S. tr. Ind. and Afr. which grow in low, peat, and well ripened cuttings root in sand under a hand-glass in moist heat.

Cress, see Lepidium, for the sake of the wild mustard; 3898.

Cress, see Lepidium, for the sake of the wild mustard; 3898.

Cress-rocket, see Vella.

Creave Hall, Cheshire, 7590.

Crichton, formerly a distinguished seat near Edin- burgh, 3868.

Crinum, hexan. monoce. and amaryllideae, S. G. peren. Amer. and Ind. which grow in rich leafy dung, in large pots, and are increased by suckers or by seeds.

Cristaria, monol. polyan. and malvaceae, a H. peren. Missouri, which grows only in peat in a shaded border, increases slowly by seeds, or dividing at the root.

Crittum, samphire, pentan. dig. and umbellifereae, a G. bien. and H. peren. which grow in light, sandy soil, and are increased by seeds, or dividing at the roots.

Crittum maritimum, the common samphire, 4728.

Cross, cruciferae, didec. and iridiceae, H. peren. Asia and Eur. bulbs of the most exquisite, 7625.

Cromartyshire, in respect to gardening, 7643.

Crome, G. his work on gardening, page 1127. A. D. 1810.

Crome Court, Worcestershire, 7566.

Crossandra, didec. angios. and acanthaceae, a S. tr. E. Ind. which thrives well in rich, light soil, and cuttings root freely in sand under a hand-glass.

Crosswort, see Crucianella.

Crotalaria, diadel. decan. and leguminose, S. and G. bien. and H. tr. E. Ind. and Afr. which grow in low and peat, and are increased by young cuttings in sand under a bell-glass; some species ripen seeds.

Crow, crotalaria and euphorbiaceae, S. tr. and an. Ind. Amer. and Eur. which grow in loam and peat, and cuttings with their leaves on root in sand under a hand-glass.

Crowberry, see Empetrum.

Crowes, decan. monog. a G. tr. N. S. W. which grows in sandy loam and peat, in an airy situation, and not over-drained, and cuttings root freely in sand under a bell-glass.

Crowfoot, see Ranunculus.

Croxdale Hall, Durham, 7584.

Crucianella, croxword, tetran. monog. and rubis- 

can, G. and H. tr. and an. Eur. of common culture.

Crux Easton, a seat in Hampshire, 7594.

Cryptis, trian. dig. and gramineae, a H. an. Eur. a grass of easy culture.

Cryptomeria, japon. monog. and orchideae, a S. parasite, which may be treated as areideae.

Cryptopsernum, tetran. monog. and nyctueaeae, a G. peren. which grows in loam and peat, and cuttings root freely under a hand-glass in sand.

Cryptostichium, syneg. polyg. trufan. and corym- biferae, H. and C. B. S. of common culture.

Culverwice, see Ayre, his works on gardening, page 1124. A. D. 1807.

Cuckoo-flower, Primros. fossculi.

Cucubalbus, campion, decan. trig. and carphophyll, a H. peren. Eng. of common culture.

Cucumber, 4727. see see Cucumis.

Cucumber, melon, water hand-glasses, 3326; culture in pots, 3271; soil, 3272; time of beginning to force, 3272; forming the seed-bed, choice of seed, sowing, 3251; treatment till removed to the fruiting-bed, 3257; forming the fruiting-bed, moulding, planting, 3258; temperature, 3259; air, 3259; water, 3258; earthing, 3259; training, 3259; setting, 3259; cutting the fruit, and saving seed, 3259; second crop in the same plant, 3259; late crops on old hot-beds, 3258; culture of melons in a dung-pit, 3219; in a filled-pit, 3230; in M'Phail's pit, 3231; under hand-glasses, 3232; on a sloping bank, 3252; insects and diseases, 3320.

Cucumis sativus, the common cucumber, sorts of described, 4708; culture in hot-beds, 4710; treatment till removed to the fruiting-bed, 3192; forming the fruiting-bed, 3199; air, 3197; water, 3197; training, 3259; culture in a filled-pit, 3268; in M'Phail's pit, 3268; in Weeks's patent frame, 3261; sorts described, 4698.

Cucurbita pepo, the pumon; C. citrullus, the water-melon; C. melo pepo, the squash-gourd; C. verrucosa, the warted gourd; C. leguminosa, the bottle-gourd; C. auranantium, the orange-fruited gourd; and C. succado, the vegetable-marrow gourd.

Cuffields, Hampshire, 7594.

Culux, the gnat, a dipterous insect, 2267.

Culling's Grove, Middlesex, 7590.

Cullen House, in Banffshire, 7564.

Culms, common, see Cyperus. Cymea, capparideae, a G. tr. and bien. and G. bien. and an. Amer. of common culture.

Cymnea, didec. dig. and cuncinacea, a G. tr. C. B. S. which grows in loam and peat, ripened cuttings root in sand under a hand-glass.

Cynanchum, cymnea, didec. monog. and salicaceae, a S. tr. and bien. and G. bien. and an. Amer. of common culture.

Cupressus, cypresse, monon. monod. and conifereae, G. tr. and C. B. S. which grow well in loam, and peat, and cuttings root in sand under a bell-glass; and H. tr. which grow in common soil, and cuttings root from sand.

Curatola, polyan. dig. and magnolacea, a S. tr. S. Amer. which thrives in sandy loam, and cuttings root in a pot of sand under a hand-glass.

Curculigo, a root which thrives well in loam and cuttings root in the same sand under a hand-glass.

Curraghmore, a seat in Waterford, 7665.

Currant, see Ribes.

Curd, Spreng., Curti Sprengel Historia Rei Herbariae.

Curtains for shelter, see Structures.
Curry, in his writings on gardening, page 1150. A. D. 1789.

Cuscuta, hasaga-tree, tetran. monog. and ..., a C. C. B. S. which thrives in loam and peat, and ripened cuttings root under a hand-glass in sand.

Curtis, Benedictus, his works on gardening, page 1130. A. D. 1569.

Curvilinear hot-houses, list of, erected by Messrs. Bailey, 1587.

Cuscuta, dodder, pentan. dig. and convolvulacea, a G. an. and H. peren. and an. Eng. and China; parasites which may be sown at the root of any bush or shrub, and they will spring up, and attach themselves to it (Curt.).

Cusking, a British writer on gardening, page 1114. A. D. 1812.

Cutting, pentan. dig. and aralin, G. tr. C. B. S. which thrive in sandy loam, and cuttings root in sand under a hand-glass.

Cutting-apple, — see Amnona.

Cuthbert Hall, Yorkshire, 7562.

Cutting as an operation on plants, 1884.

Cuttings, to propagate by, 2063.

Cyamena, hexan. monog. and hoshodelee, G. peren. C. B. S. bulbs of common culture.

Cyathia, cryptog. filices, and filiccea, a S. peren.

W. Ind. a fern of the usual culture.

Cyathus, and palmece, S. tr. E. Ind. which grow in light soil and moist heat, and are increased by seeds.

Cyclamen, pentan. monog. and primulacea, a G. peren. and H. peren. Eur. which grow in loam, and ripened cuttings root in sand and peat; and are increased by seeds; when not in a growing state, the tubers should have no winter cold.

Cyclopia, decan. monog. and leguminosea, a G. tr. C. B. S. which grows in sandy loam and peat, and very young cuttings will root readily in sand under a hand-glass, when being taken to wipe the glass frequently, to prevent their damping off.

Cydonia, quince, iocos. di-pentac. and rosaceae, F. and H. tr. Eur. and Amer. of easy culture, and increased by cuttings, layers, or grafting on thorn stocks.

Cydonia vulgaris, the common quince, pyrus cydonia, L. 1430.

Cyfartha, a seat in Brecknockshire, 7613.

Cyllista, cladoph. decan. and leguminosea, S. tr Ind. climbers which succeed well in loam and peat; and cuttings will root in sand under a hand-glass.

Cymbaria, didyn. angios. and scrophulariacea, a H. peren. Dauria, a rock-work plant, which prefers light, sandy soil, and may be increased by seeds.

Cymbidium, gynan. diam. and orchidece, S. peren. E. Ind. which thrives in sandy loam mixed with light, sandy woods, and well drained; the species are increased by dividing at the root.

Cynanchum, pentan. dig. and asclepiadacea, S. and G. tr. Eur. and C. B. S. climbers which thrive in loam and peat, and cuttings root freely in sand under a hand-glass; the H. peren. thrive in light soil, and increase freely by seeds or the root.

Cynara scolymus, the garden artichoke, 3917.

Cythara, cruciferae, iocos. cardoonf, 1529.

Cynips, the gall-fly, a hymenopterous insect, 2259.

Cynips quercus folii, the oak-gall-fly, 7075.

Cynodon, trian. dig. and gramineae, a S. peren. and H. peren. Eng. and E. Ind. grasses of the easiest culture.

Cynoglossum, hound's tongue, pentan. monog. and boraginaceae, a G. bien. an. H. peren. and an. Eng. and Amer. of easy culture.

Cynometra, decan. monog. and leguminosea, a S. tr. E. Ind. which grows in sandy loam, and large cuttings root freely in sand under a hand-glass in heat.

Cynosurus, dogstail-grass, trian. dig. and gramineae, a H. peren. and an. Eur. grasses of easy culture.

Cypros, (clion, sion, or scion, a twig of a tree), in grafting, that part which is attached to the stock, in order to become the future tree; the shoot en- grafted. — See Grafting.

Cyperus esculentus, the rush-nut, 6034.

Cyphia, pentan. monog. and campenulaceae, G. peren. cardoonf, which thrive in loam and peat, and cuttings root readily under a bell-glass in sand.

Cypres, — see Cupressus.

Cyprinus auratus, the gold carp fish, 0690.

Cysticarpus, indigo, and ericace, a G. tr. Carolina, which grows in sandy loam, and young cuttings root in sand under a bell-glass, but not freely.

Cystanthus, hexan. monog. and amarilidea, G. peren. and H. peren. which grows in sandy loam and peat, require plenty of water when in a growing state, but scarcely any when dormant.

Cystodium, gynan. monan. and orchidece, S. peren. Amer. requiring the same treatment as cymbidium.

Cysticapsus, diadel. hexan. and papaveraceae, a H. peren. of common culture.

Cytisus, diadel. decan. and leguminosea, G. F. and H. tr. Eur. As. and Amer. chiefly shrubs which prefer a light soil, and are propagated readily by seeds.

Cytisus alpinus, the tree or Scot tubarum, 7113.

Cytisus tubarum, the shrubby tubarum, 7020.

Cytisus mutisianus, Pechere d' Isabella, her work on gardening, page 1155. A. D. 1829.

D.

Dalea, pentan. dig. and asclepiadacea, a S. tr. E. Ind. which grows in loam and peat, and cuttings root in sand under a hand-glass.

Dalechampia, monoez. monad. and euphorbiacea, a S. tr. W. Ind. climbers which grow in sandy loam, and roots freely in sand under a hand-glass.

Dalhousie Castle, Midlothian, 7618.

Dalilbana, iocos. polyan. and rosaceae, a H. peren. N. Amer. a creeper, which prefers peat soil, and a shaded situation.

Dalkeith Park, Midlothian, 7618.

Dallingier, Prosper, his works on gardening, page 1158. A. D. 1738.

Dalmahoy, a seat in Midlothian, 7618.

Dalmar, Basse N. Amer. his works on gardening, page 7628. A. D. 1807.

Dalmeny Park, kitchen-garden at, 2455; hot-houses there, 2561.

Dalytown, a seat in Galway, 7672.

Daniel, the albus, or, gynan. plum, — see Prunus.

Damasium, hexan. polyg. and hydrocharideae, a S. peren. E. Ind. an aquatic.

Dampier, John, Mon. and goodenoviae, a G. peren. N. S. W. which grows well in loam and peat, and young cuttings root freely under a hand-glass in heat.

Dan y Park, a seat in Brecknockshire, 7613.

Dancourt's, a seat in Tipperary, 7667.

Dandelion, — see Leontodon.

Dandelion, a seat in Kent, 7577.

Daphne, pentan. dig. and thymeacee, a S. tr. which thrives in loam and peat, and roots by cuttings under a hand-glass, and H. tr. beautiful under shrubs, which prefer peat soil, and are increased by seeds or grafting on the D. laurea, 6562.

and G. peren. which grow in sandy loam and peat, and are increased by the division of crowns.

Dianthus, pink. decan. dig. and caryophyllum, a G. tr. and peren. and H. peren. bienn. and an. Eur. and As. which thrive in rich light soil, and thrive by cuttings or plippings and layers, in sandy loam under a hand-glass.

Dianthus caryophyllus, the carnation, 6406.

Dianthus hortensis, the pink, 1740.

Diospyros, kaki. monog. and ericace, a H. peren.

Dilapidated, an alpine, which must be grown in small pots in peat soil, and protected during winter.

Dispyros kaki, the kaki-tree, 6016.

Dicksonia, cryptog. filices and filices, a S. tr. and peren. G. peren. and H. peren. ferns of common culture as such.

Dictamnus, Dictamnus, G. fr., and peren. G. peren. which thrive well in loam and peat, and cuttings root freely.

Dick, John, of Knightbridge, a British author on gardening, page 1107. A. D. 1743.

Dictaria, finger-grass, trian. dig. and gramineae, H. an of common culture, 1662.

Dillenia, Dillenia, monog. and maranthesae, a S. bien. E. Ind. of common culture.

Dilford Park, Middlesex, 7220.

Dilwynia, D. and peren. G. peren. and H. peren. and Eur. of easy culture, and may be propagated by seeds, cuttings, or divisions at the root.

Dilpeta, synem. poly. frustans and corymbiferen, G. tr. C. B. S. which thrive well in any rich light soil, and cuttings root freely under a hand-glass.

Dietrich, Fr. Oll., his works on gardening, page 1136. A. D. 1743.

Digg, dig (dicen, Sax. to make a trench about), to break or open up the ground with a spade; in gardening, to raise, reverse, and pulverise the surface soil for eight or ten inches deep. See Digg, Digg, 1804.

Digitaria, Digitaria, gramineae, H. an of common culture, 1662.

Dillenia, is a spice. Dillenia, monog. and dilleniaceae, G. peren. grasses of common culture.

Dillenia, Dillenia, poly. and dilleniaceae, S. tr. E. Ind. which grow in low soil, and ripened cuttings, not deprived of their leaves, root freely in sand under a hand-glass.

Dillwynia, Dillwynia, decan. monog. and leguminosae, G. tr. N. S. W. which grow in sandy loam and peat, with pips peren. and ripened cuttings root freely in sand under a bell-glass.

Dimorcarpus, octan. monog. and sapindaceae, S. tr. the litchi and longan of the Chinese, China, which grow in rich loam, and have been cultivated for their fruit, 5991.

Dionesia, Venus's flytrap, decan. monog. and diosracae, a S. peren. Carolina, which thrives best when planted in a pot of sphagnum, or common moss, with a light peat mould at the bottom of the pot, and the pot placed in a pan of water.

Dioscorea, Dioscorea, hexan. and dios. and the S. peren. E. and W. Ind. climbers of easy culture.

Dioscorea, Dioscorea, sativa and alata, the yam, 6023. and 6024.

Diosma, Diosma, pentan. monog. and dioxmea, G. tr. C. B. S. which thrive best in peat soil, and young cuttings root freely in sand under a bell-glass.

Diospyros, Diospyros, date-plum, poly. dicr. and ebinaceae, S. an. G. tr. Italy, Amer. and India, which thrive well in light loamy soil, and ripened cuttings succeed best in sand under a hand-glass in heat. D. kaki, the japon date-plum, is increased byarching or budding on the common kinds.

Diospyros lotus (Ziziphus lotus, W.), the Eur. date-plant, 6024.

Diotis, Dioic, tetran. and chenopodeae, a H. tr. Siberia, which grows in any light soil, and is readily propagated by layers, and cuttings may be rooted in a hand-glass.

Diphylleia, hexan. monog. and berberidaceae, a H. peren. N. Amer. which grows freely in a light rich soil, and is increased by dividing at the root.
Diplazium, cryptog. filies and flieces, a S. peren. Jamaica, a fern which grows in loam and peat in the shade, and is increased by seed or dividing at the root.

Discaus, teal, tetran. monog. and discaues, H. bien. Eur. of common culture.

Dipteris, tonquin-bean, diadel. decan. and legumino-seae, S. tr. biennial, which grows in light loam, and ripen cuttings root in sand under a landglass in a moist heat.

Dirca, leather-sand, octan. dig. and thymelets, a H. tr. Virginia, which grows best in peat earth, and is increased by layers: slails are particularly fond of this plant.

Disa, mannan. manon. and orchideae, G. peren. C. B. S. which thrive in sand and peat, and require very little water when not in a growing state.

Disandra, heptan. monog. and pediculaceae, a G. peren. Madeira, a trailing plant of common culture.

Dipsac, gynan. monon. and orchideae, a G. peren. C. B. S. which may be treated as diis.

Diss. orient. gard., Chamber's Dissertation on Oriental Gardening.

Ditchley, a seat in Oxfordshire, 7559.

Dittany, organum dictamnus, a H. peren. Levant, which thrives in rich light soil, and is increased by seeds or dividing at the root.

Dock, see Rumex.

Dorantia, didyn. angios. and scrophulariaceae, a H. peren. Levant, which thrives in rich light soil, and is increased by seeds or dividing at the root.

D. B. S. - see Cornus.

Dolichos, diadel. decan. and legumino-seae, S. and G. tr. bien. and an. which grow freely in light rich soil, and are increased by cuttings under a landglass or by seeds, which many produce freely.

Dolichos soya, or soy plant, 6657.

Dog's-rose, climbing, a seat in Merionethshire, 7612.

Dombeya, monad. dodec. and malvacceae, a S. tr. Mauritious, which grows in sandy loam, and ripened cuttings root in a pot of sand in moist heat under a landglass.

Don, David, Esq. F.L.S., librarian to the Linnacan Society, 7045.

Don, George, of Forfar, a celebrated British botanist, 356.

Donegal, county of, as to gardening, 2278.

Donnington Grove, Berkshire, 7561.

Donnington Park, Leicestershire, 7573.

Dorothy, dry-stone walls, and alephineums, a G. peren. N. S. W. a fern of the usual culture.

Dornbach, a seat, and also a mountain near Vienna, 204.

Doronicum, lemon's bane, syngen. polyp. super. and corymbifieae, H. peren. Eur. of common culture.

Dorsetshire, gardens and residences of, 7588.

Doryanthes, tetran. monog. and urticese, Eur. and S. Amer. which grow freely in light rich soil, and increase at the roots or by seed.

Doryphorum, monog. and amarylides, a G. tr. N. S. W. which grows in loam and peat, and is increased by suckers.

Dorygium, diadel. decan. and legumino-seae, G. tr. N. S. W. which thrives in sand and peat, and young cuttings planted under a bell-glass in sand, root freely, or they may be raised from seeds.

Doucin-stocks, 4307.

Dowett-Richardot, his works on gardening, page 1121. A. D. 1808.

Down, county of, its gardens and residences, 7883.

Downing, a seat in Flintshire, 7603.

Drabas, whitlow-grass, tetrad. silice. and crucifereae, a H. peren. bien. and an. Eur. of easy culture.

Dracena, dragon-tree, hexan. monog. and asphodelaceae, S. tr. E. Ind. which thrive well in light loam, and are increased by cuttings stuck in the bark-bed when in a brisk heat root freely.

Dracocephalum, dragon's head, dildyn. gymnos. and abbineaus, a G. tr. and H. peren. and an. Eur. and Amer. of common culture.

Dracantion, dragon, heptan. monog. and aroidaceae, S. peren. India, which grow in light rich soil, and are increased by dividing at the roots.

Dragon, see Dracantion.

Dragon's head, see Dracocephalum.

Dracontium, see Dracena.

Draining, 1055.

Dreghorn Castle, near Edinburgh, 7618.

Dreystig, his works on gardening, page 1157. A. D. 1806.

Drill, (drillen, Dutc. to bore holes with a drill), a lengthened excavation formed in gardening by the hoe, for the purpose of inserting seeds. Sometimes drills are formed across beds by a large wide-toothed rake, and the same rake serves, when the plants are sprung up, to stir the soil between the rows, 1873.

Drill-rake, 1315.

Drimia, hexan. monog. and asphodelaceae, G. peren. C. B. S. bulbs which grow in sandy loam and decay quickly.

Droneingaard, a seat in Denmark, 61.

Drop, Francis, B. D., a British author on gardening, page 1101. A. D. 1672.

Drops in plants, 883.

Dropwort, spirea filiculpa.

Drosera, sundew, pentan. pagos. and droseraceae, H. peren. Irick, which grow in watery bogs in peat earth, but which will thrive and flower well when kept in small pots in the green-house. Of these plants could be filled three parts full of peat earth, and some moss placed on it, the droserae then planted in the moss, and the pots placed in pans of water." (Sweet.)

Drusenheim, a royal garden near Stockholm, 246.

Drummond Castle, in Perthshire, 7636.

Dry rot, see Merulius derneaus.

Dry-stone, its construction, 6715.

Dry-stove plants, 6663; woody sorts, 6664; climbing, 6665; succulent, 6666; bulbous, 6667; herbaceous, 6668.

Dryander, Jonas, M. D., an eminent botanist and bibliographer, who compiled the Bibliotheca Bankiana, and the greater part of the Hortus Bauhini, 7653.

Dryandra, tetran. monog. and proteaceae, G. tr. N. Hall which require the same treatment as being a herbaceous plant.

Dryas, ioea. polyg. and rosacea, a H. peren. Brit. which thrives best in a border of peat, and may be increased by cuttings dividing at the roots or by seeds, which it produces in abundance.

Dryburgh Orchard, in Berwickshire, 2220.

Drypia, pentag. tetrag. and Caryophyllaceae, a H. bien. Italy, of common culture.

Du Halde, a missionary who wrote on China and its gardening, 479.

Du Ham, Du Hamel's Treatise on Fruit Trees.

Du Plat, Hortiers, Le Chevalier Aubert Au bert, his works on gardening, page 1129. A. D. 1816.

Dublin, county of, its gardens and residences, 7585.

Dublin botanical garden, 7633.

Dublin society, 7633.

Dubois, Louis, his works on gardening, page 1121. A. D. 1804.

Duchesne, Ant. Nicholas, his works on gardening, page 1116. A. D. 1676.

Duchou, hexan. monog. and subphylum.

Duck-weed, see Lemna.

Duckfield Lodge, Lancashire, 7688.

Dudleston House, Cumberland, 7669.

Duff House, Banffshire, 7640.

Dufrasensoy, a celebrated French landscape-gardener, 165.

Duhamel, see Du Ham.

Dumb cane, see Arum.

Engler, J. Dornin, his works on gardening, page 1124. A. D. 1784.

Enkianthus, decan. monog. and erineae, a G. tr. China, which grows in sandy loam and peat, and ripens cuttings readily in pots in sand under a hand-glass without bottom heat.

Emmore Castle, Somersetshire, 7599.

Enontekis, garden of the minister there, 759.

Enoumouline (Fr.), a mode of training trees, 2150.

Entrance lodges and gates, 1712.

Enville, a seat in Staffordshire, 7570.

Ephedra, tetr. and caryophyllae, G. tr. N. S. W. which thrive in sandy peat, rough and turfy, and they require frequent shifting. “Young cuttings planted in pots in sandy loam in a bell-glass, do not in autumn or winter, or early in spring, will root freely; but not so in summer.” (Sweet.)

Ephedra, dioec. monad. and confieraeceae, H. tr. Eur. under-shrubs which grow in pot earth, and prefer a moist situation; they are readily propagated by division at the root.

Ephelis, octan. monog. and sapindae, a S. tr. Crassulaceae, in light loam, and large cuttings root best under a hand-glass in sand.

Epiconurus, gardens of, 23
Escurial, palace of, in Spain, 594.

Esher Place, formerly a seat in Surrey, 341.

Espalier trees, such as are suitable for, or are planted against, espalier rails, 5208.

Espaliers, or espalterails, raiis, timbers of timber or iron for the cultivation of fruit-trees, used as a substitute for walls, 1576.

Essex, gardens and residences of, 7539.

Estheria, a seat in Hungary, belonging to Prince Eugene of Savoy, 5236.

Ethulia, synen. polyg. equal and corymbliferas, S. an. India, of common culture.

Exhibitions, a French author on gardening, page 1115. A. D. 1533.

Etiolation, a disease of plants, 892.

Elder, J. Ch., his works on gardening, page 1125. A. D. 1702.

Eucalyptus, icos. monog. and myrtaceaee, G. tr. Austral, which grow in sandy loam or peat, and cuttings root in sand under a bell-glass, but not very freely.

Eucalyptus, decan. monog. and lignosae, a G. tr. N. Holl, which thrives in sandy loam and peat, and cuttings root freely under a bell-glass in sand.

Eucalyptus, tetrad. silic. and cruciferae, a H. an. Levant, of common culture.

Eucousis, hexan. monog. and asphodelee, G. peren. C. B. S. bulbs which grow in rich light soil, and may be propagated by offsets; or, if leaves be stripped off close to the bulb, and planted in pots of mould, they produce bulbs at their base.

Eucalyptus, hexan. monog. and amygdalice, a S. peren. Cape Horn, a bulb which may be treated as amyralis.

Eugenia, icos. monog. and myrtaceaee, S. and G. tr. Ind. and America, which thrive in two thirds loam and one third peat, and ripened cuttings root freely in sand under a hand-glass.

Eugenia jambos, the Malay apple, 5204.

Eynomus, spindie-tee, pentan. monog. and rhamn, a G. tr. and H. tr. Eur. and Amer. of easy culture in common soil, and propagated by layers, which ripened cuttings planted in autumn, or seeds.

Eupatorium, synen. polyg. equal and corymbiferas, S. tr. and H. peren. Amer. of easy culture.

Euphorbia, spurge, dodec. trig. and euphorbiaceaee, S. D. S. and G. tr. and peren. Eur. As. Afr. and America, bulbs which prefer loams and lime rubbish. Sweet says, "the way I have succeeded best in striking the cuts, is to stick them in the tan amongst the pots in a good heat, and not cover them with any glass." (Bot. Cult. 55.)

Euphorbia, eyebright, dudin. angios. and scrophulariacea, a H. an. of easy culture, 6728.

Euryale, polyan. monog. and hydrocharias, a S. an. India, an aquatic which often produces seeds, 6728.

Eutatice, the Rev. John Chetwode, a Roman Catholic clergyman, author of an eloquent classical tour in Italy, 2 vols. 4to. 1813. He died of a fever at Naples in 1815.

Eustoma, pentan. monog. and gentianae, a H. an. W. Ind. of easy culture.

Euston Hall, Suffolk, 7522.

Eutaxia, dodec. trig. and asphodelaceas, a G. peren. N. S. W. a climber which grows in sandy loam and peat, and is increased by dividing the root, or by cuttings under a hand-glass.

Eutaxia, decan. monog. and lignosae, a G. tr. N. Holl, which thrives best in sandy loam and peat, and young cuttings root freely in sand under a hand-glass.

Euthales, pentan. monog. and gardenias, a G. peren. N. Holl. which grows in sandy loam and peat, with little water, and may be increased, though slowly, by dividing the root or by seed.

Evelyn, Charles, Esq., a British author on gardening, page 1120. A. D. 1702.

Ex. Gard., Cushings' Exotic Gardener.

Exbury, a seat in Hampshire, 7594.

Excavation of ground, 1867.

Excoecaria, diec. monad. and euphorbiaceaee, a G. tr. China, which will thrive readily in light rich soil, and cuttings root in sand under a hand-glass.

Exotic culinary vegetables little cultivated in Britain, 6022.

Exotic culture, leading operations of, 5201.

Exotic esculents, not hitherto cultivated as such, 6022.

Exotic fruits, 4787.

Exotic fruits, little known, but deserving cultivation, 5074.

Exotic fruits, neglected as such, 4875.

Expedients in the management of gardens, 7446.

Exton Hall, Rutlandshire, 7579.

Eyebright, a H. an. of easy culture, 4788.

Eyetraps, in gardening, 1846.

Eywood, Herefordshire, 7588.

Exbury, a seat in Hampshire, 7594.

F. Fabricia, icos. monog. and myrtaceaee, G. tr. Austral, which thrive well in loam and peat, and young cuttings root readily under a bell-glass in sand.

Paco, Nicholas, F. R. S., a British author on gardening, page 1101. A. D. 1699.

Fagara, tetran. monog. and terebinthacees, a S. tr. and G. tr. W. Ind. and Japan, which grow in light loam, and cuttings root in sand under a hand-glass.

Fagous, decan. monog. and rutacee, a G. bic. and an. Candia and America, of common culture.

Fagus, monococ. polyan. and amaranthaceae, H. Brit. and Ire., of easy culture, and increased by seeds; and some curious varieties by grafting or budding on the others.

Fagus sylvatica, the beech-tree, 7688.

Fairchild, M. C. Thomas, his works on gardening, page 1102. A. D. 1723.

Fairly Hill, a seat in Hampshire, 7594.

Falcoiver, William, M. D., his works relative to gardening, page 1100. A. D. 1753.

Falkia, hexan. dig. and convolvulaceaee, a G. peren. C. B. S. a creeper of common culture and propagation, can be planted in pots, or cuttings, and increased by throwing the roots away.

Falkland Palace, in Fife, 357.

Falti, Francesco, his works on gardening, page 1128. A. D. 1670.

Fann, his works on gardening, page 1121. A. D. 1804.

Farn, the situation for the home-farm of a residence, 7577.

Farmer's gardens of Middlesex, 7519.

Farmer's gardens, their formation, 7593.

Farn Hill, a seat in Tyome, 7679.

Farnham House, a seat in Surrey, 7676.

Farrington House, Devonshire, 7660.

Farsetia, tetrad. silic. and cruciferae, G. tr. Eur. which grows in loam and peat, and young cuttings root in the same soil under a hand-glass; and H. peren. and an. rock-work plants, which are increased by dividing the roots or by seed.

Fate gardens at Canton, 477.

Fawley Court, Buckinghamshire, 7587.

Feberries, a local name for gooseberries, — see Ribes.

Febees, a local name for gooseberries, — see Ribes.

Feather-grass, stipa pennata.

Feda, tricolor, polyan. and dipacaeas, a H. tr. and an. Eur. of easy culture.

Felbrig, a seat in Norfolk, 7554.

Flichio Tarkan, a seat in Hungary, 206.

Felix Hall, Essex, 7542.

Fellenberg, M., a celebrated Swiss agriculturist, 1034.

Felling trees, 6523. to 6909.
Fellow, swertia perennis.
Fenno-wool, best treatment, 6798.
Fences, barriers for enclosure and defence; they are either live fences, formed by connected lines of woody plants, or dead fences, formed of stone, iron, timber, or other mineral or dead vegetable matter.
Fences for plantations, 6820.
Fences in landscape-gardening, 6874.
Fennel, 4007, — see Anethum.
Fennel-flower, — see Nigella.
Fenugreek, — see Trigonella.
Fernmagh, gardens of, 7677.
Ferne orne, 7580.
Fernatini, D.— Louis, his tract on the genus Fimia, page 1128. A. D. 181—
Fernery, the seat of Vorniart, near Geneva, 240.
Fernhill, a seat in Hampshire, 7594.
Ferns, exotic, their culture, 6738.
Ferns, peren. Brit.-am. fonce, monc. and, — a S. tr. E. Ind. which grows in loam and peat, and cuttings root in sand under a hand-glass.
Ferrari, John Baptist, his works on gardening, page 7677, A.D. 1833.
Ferraria, monadel. trian. and iridee, G. peren.
C. B. S. bulbs which may be treated as iaia.
Ferris, giant fern, Pent. dig. and umbilliferae, H. S. A. which grow in common garden soil, and are increased by seeds.
Fescue-grass, — see Festuc.a.
Fescue, fens. gras, fran. dig. and graminne, H. tr. and an. Eur. of the easiest culture.
Feteption, K. G., his works on gardening, page 1124. A. D. 1780.
Feverfew, — see Pyrethrum.
Fever-wort, — see Triosteum.
Ficaria, pleswort, polyan. polg. and ranunculaceae, a H. perren. Brit. of common culture.
Ficus carica, the fig-tree, 4839; culture of the fig in houses, 5143; in the stove, 3161; in the open ground, 4851.
Field, Mr. Henry, his history of the Chelsea garden, page 1118. A. D. 1839.
Fitches, gardens of, 7615.
Fig-house, construction of, 5674.
Fig-marigold, — see Mesembryanthemum.
Fig-tree, — see Ficus.
Figwort, — see Scrophularia.
Filago, cotton-rose, syng. polg. super. and co-rimbifere, a H. an. S. Eur. of common culture.
Flach, N., his works on gardening, page 1119. A. D. 1783.
Filmy leaf, hypophyllum tunbridgeense.
Finborough Hall, Suffolk, 7553.
Finger-grass, — see Dactyria.
Finneley Park cottage, Yorkshire, 7592.
Finocchi, Anton, Maria, his work on gardening, page 1119. A. D. 1780.
Fish-tree, — see Pinus.
Fischer, V. F., his work on truffle hunting, page 1125. A. D. 1783.
Fisher, Dick, formerly a seat in Warwickshire, which was burnt out by Brown, and described by Wheatley.
Fitness, a beauty in gardening, 7168.
Fitzwillers, a seat in Essex, 7541.
Flax, — see Linum.
Flax, — see Linum.
Flax-lily, phorionum tenax.
Flax-bane, — see Coryza.
Flax-root, initia pulicaria.
Fleetwood, William, a British author on gardening, page 1101. A. D. 1707.
Flemingia, diadel. decan. and leguminosae, S. tr. peren. and ibn. India, which grow freely in loam and peat, and cuttings root under a hand-glass in sand plunged in heat.
Fleurs, a seat in Roxburghshire, 7281.
Flora, the cultivation of, 7006.
Flixton Hall, Suffolk, 7552.
Flخيرweed, syzygium sophia.
Florence Court, a seat in Cavan, 7767.
Florics, the 1747.
Floricultural catalogue, 6290.
Florimania, 146.
Florists, or floristry gardeners, 7387.
Flower, flowers, enumeration of, 6921.
Florists' gardens, commercial, their formation, 7547; management, 7407.
Florists' society of Paisley, its origin, rules, &c. 7628.
Florists' societies, 7706.
Flower Hil, a seat in Galway, 7672.
Flower, see of Veroniana.
Flower-garden, formation of, 6076; exposure and aspect, 6380; extent, shelter, soil, surface, vulgarities, of, &c. 6091 to 6098; laying out the area, 6096; placing the hot-houses, 6099; flower-nursery, 6104; walks, edgings, basket-edgings, &c. 6105 to 6108.
Flower-gardens, its culture and management, 6187; times of planting or sowing, 619; pruning and training, &c. 619; grass-plots, 6195; protecting tender plants, 6192; water, 6193; insects and weeds, — seeing off decaying flowers and hortage, 6195; gathering flowers, 6193; ordering seeds and bulbs, &c. 6200; neatness, 6201.
Flower-garden, planting of, 6110; mingled garden, 6111; select garden, 6119; botanic flower-garden, 6192; decorations, 6127.
Flower, 1407.
Flower-stage, for pots of plants, 1526.
Flowering ash, — see Ormus.
Flowering fern, — see Schizodon.
Flowering rush, butomus umbellatus.
Flowers for borders, — see Border-flowers.
Flux of juices, a disease of plants, 885.
Fogg, 1790.
Fontainbleau, blue or clear fountain, a royal residence near Paris, the gardens of which are noted for the precocity and excellence of their grapes, 159.
Fontaine, Louis de, his works on gardening, page 1119. A. D. 1788.
Foreign dian. monog. and onagraceae, a H. tr. Syria, a shrub rather tender of frost, but which grows in common soil, and is increased by layers, or cuttings planted under a hand-glass.
Fonthill Abbey, Wiltshire, 7597.
Fool's parsley, — see Æthusa.
Footear Place, Kent, 7588.
Fouquier on Tulip-trees, by W. Forsyth, Esq. royal gardener, — see page 1110. A. D. 1791.
Foxwell, a seat in Middlesex, 7590.
Foreign exotic culinary vegetables little cultivated in Britain, 6022.
Foreign fruits deserving introduction and cultiva-
tion, 1834.
Foreign fruits of Africa, 6018.
Foreign fruits of Asia, 6021.
Foreign fruits of South America, 6020.
Foreign fruits of the West Indies, 6019.
Foreign hardy culinary vegetables little cultivated in Britain, 4306.
Foremark, a seat in Derbyshire, 7574.
Foremen of gardens, 7581.
Forfar botanic garden, 7651.
Forfar gardens of, 7637.
Forficus auriculata, the earwig, a coleopterous insect, 2257.
Forking, 1872.
Forking, a, a hypenopterous insect, which may be collected by whelming empty pots with the holes in their bottoms closed, near their holes in the ground, should be moistened with horned water or with milk, 2262.
Fordhook, Esq. his works on gardening, page 1119. A. D. 1791.
Forty Hall, a seat in Middlesex, 7520.
Forst, myrt. and amaranth, a H. peren.
N. Amer. which require a peat soil, and are increased by layers.
Foulkebourne Hall, Essex, 7542.
Fountains and other hydraulic devices, 1829.
Foxglove, — see Digitalis.
Foxley, a seat in Herefordshire, 7588.
Foxtail-grass, — see Alopecurus.

Gardini, M.— his works on gardening, page 1128.
A. D. 1783.
Garidella, decan. trig. and ranunculaecea, a H. an.
France, of common culture.
Garland-flower,— see Hedychium.
Garlic,— see Allium.
Garlic-pear,— see Crataeva.
Garthouse, a seat in Perthshire, 7636.
Garnder, Claude, a French author on gardening, page 1112. A. D. 1615.
Garnons, a seat in Herefordshire, 7568.
Garten baumeister, 256.
Garten, James, an English author on gardening, page 1107. A. D. 1769.
Garuga, decan. monog. and,— see A. fr. E. Ind. which may be treated like galega.
Gasteria globosa, decan. monog. and leguminaea, a G. tr. N. Holland which grows in loam and peat, and ripened cuttings root in sand under a hand-glass.
Gatcombe House, Hampshire, 7594.
Gatcombe Park, Worcestershire, 7565.
Gates, different kinds of, 1794; maintenance in pots, 1795.
Gates and lodges, 1712.
Gathering vegetables, operation of, 2288. to 2290.
Gatton Park, Surrey, 7528.
Gaulston Park, in Westmeath, 7602.
Gautherius, decan. monog. and ericeae, H. tr. N. Amer. creepers which thrive best in peat soil, and are increased by layers or seeds.
Gautherius serpyllifolia, the common snowberry, 478.
Gaura, octan. monog. and onagraceae, a S. tr. F. bien. and H. an. Amer. of easy culture.
Gaufter, Giuseppe, his works on gardening, page 1128. A. D. 1818.
Gazania, syng. polyg. frutetan. and corymbiferae, a G. tr. C. B. S. which thrives in light, rich soil, and cuttings root freely in the same soil under a hand-glass.
Gehler, Fr. X. his works on gardening, page 1123.
Geissorhiza, tile-root, trian. monog. and irideae, G. peren. C. B. S. which may be treated like ixies.
Gelium, dioec. icos. and ——, a S. tr. E. Ind. which may be treated like gardenia.
Gelium, pentan. monog. and apocynaeae, a H. tr. N. Amer. of easy culture.
Gems, to propagate by,— see Bulbs.
Genip-tree,— see Genipa.
Genipa, genip-tree, pentan. monog. and rubiacceae, S. tr. S. Amer. which may be treated like gardenia.
Genista, diadel. decan. and leguminaeae, G. and H. tr. of easy culture, and increased chiefly by seeds.
Genip-blossom, Ch. heat, his works on gardening, page 1125. A. D. 1796.
Gentian, — see Gentiana.
Gentiana, gentian, pentan. dig. and gentianaeae, H. peren. Eur. and Amer. and annuals, which grow best in peat and loam, and the smaller sorts in pots; they are increased by cuttings, or dividing at the root.
Geodorum, gynan. monan. and orchidaceae, S. peren. E. Ind. which grows best in sandy loam and peat, and the only mode of increasing them is by division at the root.
Geoffroy, bastard cabbage-tree, diadel. decan. and leguminaeae, a S. tr. Jamaica, which grows in sandy loam, and cuttings root in the same soil under a hand-glass.
George, J. — his works on gardening, page 1131. A. D. 1793.
Ger. herb. J. Gerarde's herball.
Gerrania, table of species and varieties, 6601; pro-duced from cultures, 6905; forcing, 6904.
Gerardin, John, a British writer on gardening, page 1099. A. D. 1507.
Gerardia, didym. angios. and scrophularineae, a S. peren. and H. peren. and an. E. Ind. and N. Amer. of easy culture.
German authors on gardening, 7693.
Germantown, in Pennsylvania.
Geropogon, old man's beard, syng. polyg. equal. and cichoraceae, a H. peren. and an. Italy, of common culture.
Gerrit De Allius, his writings on gardening, page 1125. A. D. 1788.
Gesner, John, his works on gardening, page 1123.
Geesneria, didym. angios. and bignoniaceae, S. tr. Amer. which thrive well in light rich soil, and cuttings root either in sand or mould, under a hand-glass.
Gethyllis, hexan. monog. and amaryllidaceae, G. peren. C. B. S. bulbs which may be treated like ixias.
Gethyline, decan. monog. and combracteeae, a S. tr. E. Ind. which grows best in loam and peat, and cuttings root in sand under a hand-glass in heat.
Geyn, Ivens, iocos. polyg. and rosaceae, H. peren. N. Amer. and Eur. of the easiest culture.
Ghent, villas of, 123; botanic garden, 138.
Ghania, dian. monog. and verbenacceae, a S. an. of common culture.
Giant fenkle, — see Feronia.
Gibside, a seat in Durham, 7365.
Gibson, John, A. D. 1760. his writings on gardening, page 1107. A. D. 1768.
Gibson, T., his works on gardening, page 1107. A. D. 1768.
Gillian, John, a British writer on gardening, page 1107. A. D. 1767.
Gillingham Hall, Norfolk, 7554.
Gillett, the Rev. William, his works relative to gardening, page 1107. A. D. 1763.
Ginseng, panax quinquefolium.
Girdling trees, 863.
Glisekia, pentan. pontag. and portulacceae, a S. an. W. Ind. of common culture.
Great Fulford, a seat in Devonshire, 7600.

Greek valerian,—see Polemonium.

Green dragon, arum dracountium.

Green-house, its construction, 6104; general-culture, 6302.

Green-house plants, 6597; select sorts, 6598. to 6618; woody sorts, 6621; climbers, 6652; succulents, 6659, 6665, 6667. Dianthus, 1759; selections for particular purposes, 660. Greenecroft, a seat in Durham, 7384.

Greenstead, Hall, Essex, 7341.

Greenwich Park, Kent, 7355.

Grenada, gardens of, 292.

Grevillea, tetran. monog. and proteaceae, G. tr. N. S. which thrives in sand and peat, and ripened cuttings root under a hand-glass in sand.

Griselinia, the anchovy-pear, polyan. monog. and guttifereae, a S. tr. Jamaica, 6979.

Grielum, decan. pentag. and germanicae, a G. peren. C. B. S. which thrives best in sandy gravel, with the pots well drained, and cuttings root in the same soil without glasses.

Griffin, Mr. William, his writings on gardening, page 1113. A.D. 1789.

Grimsdorpe Hall, Lincolnshire, 7571.

Grimsdorpe, Stone, Yorkshire, 7382.

Grindelia, sygnet. polyg. super. and corymbifereae, G. tr. N. S., which thrive well in light, rich soil, and young cuttings root freely in the same soil under hand-glasses.

Grinsargem, a seat in Glamorgan, in.

Grisenthwait, Mr., an apothecary at Wells, Norfolk, and agricultural writer, 1050.

Grislea, octan. monog. and salicaceae, a S. tr. Eu. Ind., which thrives in loam and peat, and young cuttings root freely in sand under a bell-glass in heat.

Grohan, — his works on gardening, page 1125. A.D. 1788.

Gromwell, — see Lithospermum.

Groningen, botanic garden of, 133.

Gronovia, pentan. monog. and cucurbitaceae, a S. peren. Jamaica, a climber, which thrives well in rich soil, and cuttings root readily under a hand-glass in heat.

Grottoes, as decorations in gardening, 1815.

Grown, how to operate on, in landscape-gardening, 7196.

Ground cakes, 1306.

Ground-livy, — see Chamaedium.

Ground-measure, 1363.

Ground-pine, ajuga chamapitaya.

Grounds, the art of laying out, — see Landscape-gardening.

Groundsel, — see Senecio.

Groundsel-tree, baccharis halimusvillea.

Grove, a seat in Herefordshire, 7244.

Grove, a seat in Middlesex, 7260.

Grove Cottage, Oxfordshire, 7538.

Grove Hill, Surrey, 7297.

Grun, (garden, Toot, to delve or dig), to root up trees which are not to be planted again: to clear the ground of ligneous vegetables by digging round and cutting their roots.

Guaiacum, lignum vitae, decan. monog. and rutaceae, a S. tr. W. Ind. which grows in loam and peat, and ripened cuttings taken off at a joint, root freely when planted in a pot of sand, and plunged under a hand-glass in heat.

Guarea, octan. monog. and meliaceae, a S. tr. S. Amer. which grows freely in loam and peat, and ripened cuttings root in sand under a hand-glass.

Guatteria, polyan. polyg. and ananasceae, a S. tr. Jaquinaeae, which requires a loamy soil, and ripe cuttings root under a hand-glass.

Gueder-rose,—see Viburnum.

Guern, — Hall, a French author on gardening, page 1117. A.D. 1773.

Guerin and Schwartz, their work on gardening, page 1122. A.D. 1813.

Guettarda, monoch. hexan. and rubicaceae, S. tr. South America, treat as gardenia.

Guilandina, nicker-tree, decan. monog. and leguminoseae, a S. tr. India, which thrives in loam and peat, and young cuttings root in sand under a hand-glass.

Guimpel, F.,—his works on gardening, page 1127. A.D. 1810.

Guiteling Park, Gloucestershire, 1565.

Gum-sucoory, chondrilla junceae.

Gundelia, sygnet. polyg. segr. and caryophyllumae, a H. peren. Lerant, of common culture.

Gunnadia, gynan. diae and urticaceae, a G. peren. C.B.S. which may be treated as an aquatic.

Gummersbury, a seat in Middlesex, 7250.

Guy’s Cliffs, a seat in Warwickshire, 7571.

Gynanedia, gynan. monan. and orchideae, a H. peren. Brit. which grows best in sandy loam, peat, and sand and may be increased by seeds; if planted in pots they must be well drained.

Gymnema, pentan. dig. and asclepiadaceae, a S. tr. Ceylon, which grows in loam and peat, and cuttings root freely under a hand-glass.

Gymnocalcudus canadensis, dioc. decan. and legumino- seae, a H. tr. Canada, which grows in common soil, and is increased by cuttings of the root.

Gymnostyles, sygnet. polyg. necess. and corymbifereae, a G. an. S. Amer. of common cult. ure.

Gypsophila, a plant, herb, and Caryophyllaceae, H. peren. and an. Eur. well adapted for rock-work, and propagated by cuttings or seeds.

Gypsium, 1729.

Gyposia, a species, monog. and hemodoraceae, a G. peren. N. Amer. which grows well in light soil, and may be increased by dividing at the root.

H.

Habennaria, gynan. monan. and orchideae, H. peren. Eur. and Amer. requiring the same treatment as gymnadenia.

Haggy, a north country term for a pick-axe,—see Pick-axe.

To hack (hacken, Teut. to hew), to cut over or clear away, by cutting ligneous vegetables.

Hackfall, scenery of, in Yorkshire, 7392.

Hackney, scenery of, in Yorkshire, 7392.

Hackney botanic nursery garden, 7556.

Hackwood Park, Hampshire, 7549.

Haddon Hall, Derbyshire, 7243.

Haddow Hall, Lancashire, 7388.

Haemantlhus, hexan. monog. and amaryllidaceae, G. peren. S. W. A. which thrive best in sandy loam and peat, and like other bulbs require no water when in a dormant state.

Haematoxyln, logwood, decan. monog. and leguminoseae, G. an. S. Amer. which grows in loam and peat, and cuttings root readily in sand under a hand-glass.

Hakone, a species, monog. and hemodoraceae, a G. peren. N. S. W. a bulb which may be treated as hemanthus.

Hafod, a seat in Cardiganshire, 7607.

Hale, a seat in Stockholm, 7346.

Hagley Hall, Staffordshire, 7570.

Hagley, Worcestershire, 7566.

Hall, Lancashire, 7588.

Hair-grass,—see Alfa.

Hakea, tetran. monog. and proteaceae, G. tr. Austral. which thrive well in a third loam, a third peat, and a third sand, and that pots well drained, and too much watering avoided; ripened cuttings root readily under a hand-glass in sand.

Halliday, Housie, Devonshire, 7600.

Halesia, snowdrop-tree, dovecole. monog. and ebe- aceae, H. tr. N. Amer. which grow freely in common soil, and are increased by cuttings of the roots.

Halifax, — see Eborac.

Hall, Joseph, his work on gardening, page 1100 A.D. 1665.

Hallifax, monog. angios. and scrophulariaceae, a G. tr. C.B.S. which grows freely in loam and peat, and ripened cuttings root readily in sand under a hand-glass.

Halodendron, decan. and leguminoseae, a G. tr. and bien. and peren. C.B.S. which grow freely in loam and peat, and young cuttings root under a hand-glass.

Haloragis, ocatnd. tetrat. and onagraceae, a G. tr. N. Zeal. which may be treated as hallia.

Halswood, a seat in Sligo, 7675.

Ham Court, Worcestershire, 7566.
Ham House, Middlesex, 327.

Hamamelis, tetran. dig. and berberisace, a H. tr. N. Amer, which thrives in common soil, and is generally increased by layers.

Hamelin, the Hon. Charles, of Painshill, a man of great taste in gardening, page 1117. A.D. 1750.

Hamels, a seat in Hertfordshire, 7544.

Hamlet, the Hon. Charles, of Painshill, a man of great taste in gardening, page 1117. A.D. 1750.

Hamilton, the Hon. Charles, of Painshill, a man of great taste in gardening, page 1117. A.D. 1750.

Hammer, or nocul., or common, Henry Lewis du, a French author on gardening, page 1117. A.D. 1750.

Hammer Hall, in Herts, 7546.

Hammond, a seat in Hants, 7546.

Hammond, the Hon. Charles, of Painshill, a man of great taste in gardening, page 1117. A.D. 1750.

Hammond Palace, Larneke, 7569.

Hammonitex, oil-nut, for dec, and terebinthace, a G. tr. N. Amer, which grows in warm and peat, and cuttings root under a hand-glass in sand. Hammer, 1345.

Hamshire, gardens and gardens, page 7549.

Hampton Court, Herefordshire, 7568.

Hampton Court, Middlesex, 7553.

Hamble Hall, Worcestershire, 7566.

Hand-glasses, of different kinds, 1429.

Hammer Hall, Flintshire, 7566.

Hansom, a seat in Norfolk, 7554.

Ham, garden of the, 758.

Hard-grass, — see Rottboellia.

Hard-wooded timber-trees, the most useful sorts of, described, 7588.

Hardwick Hall, Derbyshire, 7575.

Hardwicke, a seat in the county of Durham, 7585.

Hardy fruits, catalogue of, 4361.

Hardy trees, with showy flowers, 6539; deciduous, 6540; evergreen, 6541.

Hare Hall, Essex, 7541.

Hare-street Cottage, Essex, 7541.

Hares, to prevent from barking trees, 6934.

Hare's ear, — see Bupleurum.

Harvest-tong, davailla canariensis.

Harestail-grass, lagurus ovatus.

Harewood, a seat in Herefordshire, 7568.

Harewood House, Yorkshire.

Harrington House, Hornsey, account of the extensive steam apparatus erected there, 1699.

Harrison, Mr. Charles, F.H.S., his writings on gardening, page 1109. A.D. 1815.

Hartill, Samuel, his works on gardening, page 1100.

Hart's tongue, scopolium officinarum.

Hartwort, — see Torgyllum.

Hassagay-tree, curtisia fastigia.

Hatchet-vetch, — see Biserrula.

Hatfield House, Hertfordshire, 7545.

Hathorney House, Midlothian, 7518.

Hawick nursery, Roxburghshire, 7562.

Hawskyne Park, Shropshire, 7569.

Hawkweed, — see Hieracium.

Hawm, or hawn (heauton, Sax.), the lower part of the straw after the ears are cut off; in gardening, the term is generally applied to leguminous vegetables, after their produce has been gathered.

Haworth, Adrian Hardy, Esq., his writings on gardening, page 1110. A.D. 1794.

Hawthorn, mespilus oxyacantha, — see Mespilus.

Hay, Mr. John, planner of gardens, Edinburgh; an excellent horticulturist, and a good man, 2970.

Hayes Place, Kent Road, 7537.

Haynes, Thomas, his works on gardening, page 1113.

Haywood, Joseph, gent., his writings on gardening, page 1114. A.D. 1818.

Head, or upper gardener, 7583; who ought to recommend him. Heas, a seat in Eastmeath, 7561.

Heading, the growing of the leaves of a plant into a common bough, as in the common cabbag, cabbag, or cabbage, as in the common cabbage; called also cabbagging, or loafing.

Heart's ease, viola tricolor.

Heartseed, — see Cardiospermum.

Heart's ease, — see Helxine.

Heat, 1196.

Heath, — see Erica.

Heathfield, a seat in Kent, 7537.

Heathfield Park, Sussex, 7531.

Heaton Hall, Northumberland, 7586.

Heaton Lodge, Lancashire, 7588.

Hebe, cabbaging, or asclepiadace, a S. tr. Ceylon, which delights in light, rich soil, and cuttings root readily under a hand-glass in a pot of sand plunged in a little heat.

Helenium, monog. and hemicallidace, H. peren. Eur. and China, of easy culture in any soil.

Helicen, monog. and hemicallidace, a S. tr. Ceylon, which delights in light, rich soil, and cuttings root readily under a hand-glass in a pot of sand plunged in a little heat.

Helenium, monog. and hemicallidace, H. peren. Eur. and China, of easy culture in any soil.

Helenium, monog. and hemicallidace, a S. tr. Ceylon, which delights in light, rich soil, and cuttings root readily under a hand-glass in a pot of sand plunged in a little heat.

Helenium, monog. and hemicallidace, H. peren. Eur. and China, of easy culture in any soil.

Helenium, monog. and hemicallidace, a S. tr. Ceylon, which delights in light, rich soil, and cuttings root readily under a hand-glass in a pot of sand plunged in a little heat.

Helenium, monog. and hemicallidace, H. peren. Eur. and China, of easy culture in any soil.

Helenium, monog. and hemicallidace, a S. tr. Ceylon, which delights in light, rich soil, and cuttings root readily under a hand-glass in a pot of sand plunged in a little heat.

Helenium, monog. and hemicallidace, H. peren. Eur. and China, of easy culture in any soil.

Helenium, monog. and hemicallidace, a S. tr. Ceylon, which delights in light, rich soil, and cuttings root readily under a hand-glass in a pot of sand plunged in a little heat.

Helenium, monog. and hemicallidace, H. peren. Eur. and China, of easy culture in any soil.

Helenium, monog. and hemicallidace, a S. tr. Ceylon, which delights in light, rich soil, and cuttings root readily under a hand-glass in a pot of sand plunged in a little heat.

Helenium, monog. and hemicallidace, H. peren. Eur. and China, of easy culture in any soil.
Hot-houses, contrivances for procuring water, wind, and air, 1698.

Hot-houses, details of the construction of their roofs, 1101; fixed roofs, moveable roofs, roots partaking of both characters, materials of fixed roofs, of moveable roofs, up-guts, and objections to moveableness, 1695, to 1696.

Hot-houses, their pits, stages, shelves, doors, paths, &c. 1681; materials of the path, pits for tan or earth, beds and borders, shelves, stages, 1692. to 1697.

Hot-houses, their steam-boilers and tubes, 1665; steam-boilers, of cast-iron, of wrought-iron, of copper, steal, wood; hot water, 1695.

Hot-houses, their trellises, 1671; back wall trellis, middle trellis, front or roof trellis, fixed rafter trellis, moveable rafter trellis, secondry trellis, cross trellis, 1672. to 1697; Hot-house entrance, 1680.

Hot-houses, their walls and sheds, 1640; front wall, holes for vine-stems, back wall, back shed, 1641. to 1647.

Hot-houses of the Chinese, specimen of, 489.

Hot-houses used in horticulture, 6161.

Hot-houses used in horticulture, their culture and management, 6202.

Hot-houses used in horticulture, their culture and management, 6244.

Hottentot cherry, cassine malaccenicia, 1671.

Hottonia, water-violet, pentan, monog. and primulaeaceae, 1671.

Houghton Hall, Norfolk, 7555.

Hound's tongue, see Cynoglossum.

House, or mansion, situations best adapted for, 7295; 2nd ed., 1682.

House, with carriage entrance, as a residence, 2029; with covered entrance, 2030; house and conservatory, 2041; house and flower-garden, 2022; house of French patrons, 2033; house and front garden, 2034.

Houseleek, see Sempervivum.

Housman, tr. monog. and rubicaceae, H. peren. N. Amer. rock-work plants, which do well in peat soil in pots.

Hovea, diadel, decam. and leguminosae, G. tr. Aus- tral, which thrive in loam and peat, and young cuttings may be struck under a bell-glass in sand.

Hovenia, pentan. monog. and rhamnaceae, a G. tr. Japan, which grow in leam and peat, and ripened cuttings root readily under a half-glass in sand.

Howick, a seat in Northumberland, 7587.

Howsham, a seat in Yorkshire, 7594.

Hoya, pentan. dig. and asclepiadaceae, a S. tr. Asia; a climber of easy culture.

Huiber, Cand. his works on gardening, page 1125.

Huiber, Francis, a natural philosopher of Geneva, who wrote on bees, 1738.

Hühner, K. Jos., his works on gardening, page 1126.

Huinera, pentan. dig. and asclepiadaceae, D. S. tr. C.B.S. succulents, which grow in brick and lime-rubbish, little watered; cuttings root easily.

Huicke, William, his works on gardening, page 1101. A. D. 1665.

Huisk, Robert, author and translator of some plays and novels, and of a work on bees, of which in- sect he is an enthusiastic admirer and cultivator, 1738.

Hull botanic garden, 7581.

Humble, William, his works on gardening, page 1101. A. D. 1665.

Hulse, Robert, author and translator of some plays and novels, and of a work on bees, of which in- sect he is an enthusiastic admirer and cultivator, 1738.

Hull botanic garden, 7581.

Humes, pentan. dig. and asclepiadaceae, a G. bien. N. S. W. of easy culture.

Humphrey lupinus, hop, pentan. and urticaceae, a tr. See 3042.

Hundeshagen, C., his works on gardening, page 1127. A. D. 1819.

Huntingdonshire, gardens and residences of, 7550.

Hura, sandbox-tree, monac. monod. and euphor- biaceae, which grow freely in light loam, and large ripened cuttings root in sand under a half-glass in heat.

Hurstwick, Hamphire, 7594.

Hutchinsia, trit. silic. and cruciferaceae, H. peren. and a bien. Eur. rock-work plants which grow in loam and peat, and root freely.

Hylten, his works on gardening, page 1129. A. D. 1817.

Huts, as garden buildings, 1781.

Hyacinth, see Hyaenanthus.
Hyacinthus, hyacinth, hexan. monog. and asphodele, H. peren. Eur. bulbs of easy culture.

Hyacinthus orientalis, 6252.

Hydnum, hydnum, manihotella, globosa.

Hydnum, dodec. dodec. and hydrocharideae, G. tr. C.B.S. which grows in loam and peat, and may be increased by cuttings in sand under a bell-glass.

Hyde Hall, Cheshire, 7590.

Hydrangea, decan. dig. and saxifragae, F. and H. tr. which grows best in common soil, and ripened cuttings root readily.

Hydrangea hortensis, 6476.

Hydrocotyle, hydrocotyle, H. tr. S. Amer. Which thrives well in loam and peat, and ripened cuttings root freely under a hand-glass.

Hydrocharides, hand-glass, hand-glass, and ranunculacea, H. peren. Eng. Where grows freely in light soil, and increased by division at the root.

Hydrocotyle, water-leaf, monog. and bo-ragineae, H. peren. Which grows freely in and of light, rich soil, and are increased by suckers from the roots.

Hydrolymus, virginicum, or Shavanese salad, H. peren. Easy root in soil.

Hydrolymus press, its use in gardening, 1470.

Hygrometer, its use in gardening, 1383.

Hyemenaea, decan. monog. and leguminoseae, S. tr. Eng. Which grows freely in and of light, rich soil, and are increased by suckers from the roots.

Hygrophilus, water-leaf, monog. and bo-ragineae, H. peren. Which grows freely in and of light, rich soil, and are increased by suckers from the roots.

Hygrophila, cichoraceae, H. tr. Virginia, which grows best in light soil, and increased by cuttings in sand under a bell-glass.

Hygrophila, cichoraceae, S. tr. Florida, which grows best in light soil, and is increased by layers, or ripened cuttings in sand under a bell-glass.

Hygrophila, cichoraceae, S. tr. Florida, which grows best in light soil, and increased by cuttings in sand under a bell-glass.

Hymenophyllum, common holly, 7115.

Hyssopus, hyssopus, Hyssopus, aniseed-tree, polyg. and magnol.aceae, a. F. tr. Florida, which grows best in light soil, and is increased by layers, or ripened cuttings in sand under a bell-glass.

Hyssopus, hyssopus, Indigofera, S. tr. and E. tr. Which grow in light soil and peat, and cuttings root in sand under a hand-glass in heat.

Hyssopus, syngeny, polyg. equal. and corymbifera, H. peren. and an. Eur. of common culture.

Hyssopus, polyg. an. and Eru. of easy culture.

Hyssopus, syngeny, polyg. equal. and corymbifera, H. peren. and an. Eur. of common culture.

Hypecoum, St. John's Wort, polyd. polyan. and hypericinoseae, G. tr. Eng. and Amer. Which grow in loam and peat, and young cuttings root freely under a bell-glass, H. tr. and peren. Of easy culture; some are increased by cuttings from a hand-glass, and others by divisions at the root.

Hypecoum, cat's ear, syngeny, polyg. equal. and corymbiferae, H. peren. and an. Eur. of easy culture.

Hypecoum, mascatula, 4905.

Hypecoum, hexan. monog. and asphodeleae, H. peren. Amer. and C. B. S. Which grow in loam and peat, and are increased by offsets from the plants.

Hypisis, inami, gymnoseae and labiateae, S. and G. tr. bienn. and peren. Ind. and Americia, which grow freely in rich, light soil, and the hot-house sorts are increased by cuttings under a hand-glass in heat.

Hyssop, see Hyssopus.

Hyssopus, didec. dodecad. and labiateae, H. tr. and peren. Eur. and N. Amer. of easy culture.

Hyssopus officinalis, the common hyssop, 4321.
to cut or prune), French pruning-shears, hedge-shears, verge-shears, turf-shears, scythe, garden-scarifiers or bark-shearers, moss-scraper, blunt knife, garden-hoe, garden-hedge, garden-pincers, weeding-pincers, grape-gatherer, peach-gatherer, pear-gatherer, berry-gatherer, and cherry-gatherer, climbing-spur, 1326. to 1359.

Inula, syngen. polyg. super. and corymbiferae, S. an. and H. peren. Eur. and Asia, of the easiest culture.

Inula crithmifolia, samphire, 4581.

Inula helenium, elecampane, 4540.

Inverary Castle, Arg. County, Scotland, 7649.

Invercauld House, Aberdeenshire, 7639.

Invergordon Castle, Ross-shire, 7647.

Inverness nursery, 7648.

Ionidium, peren. monog. and violaccae, A. peren. S. Amer. which grows freely in land and peat, and young cuttings root readily under a hand-glass.

Ipomoea, peren. monog. and convolvulaceae, S. peren. and an. Ind. Amer. Eur. twiners which grow in rich light soil, and young cuttings root freely in sand under a hand-glass; the H. peren. and an. are of the easiest culture.

Ipomopsis, peren. monog. and polonoinaceae, A. peren. and an. H. an. N. Amer. of common culture.

Ireland, gardens and residences of, 7651.

Iresine, diaec. peren. and amaranthaceae, a F. peren. Amer. which grows in land and peat, and is increased by dividing at the root.

Iris, trian. monog. and irideae, G. H. peren.

Irrigation, 1098.

Isatis, wod, treed. silic. and cruciferiae, a H. peren. and an. Ind. Amer. grows well and analy in a peat.

Iscopogon, polyg. monoc. and garamineae, a S. peren. and an. E. Ind. Grasses of common culture.

Isle of Anglesea, gardens and residences of, 7603.

Isle of Man, as to gardening, 7589.

Isle of Jersey and Guernsey, as to gardening, 7598.

Islandia, tetran. monog. and onagraceae, a H. an.

Eur. of common culture.

Isotoma, corymbiferece, an. and orchideae, S. peren.

W. Ind. parasites which may be treated as aeriades, epipendrums, &c.

Jasminum, corymbiferece, an. and cricospheice, a H. peren. and an. Eur. of easy culture.

Italian books on gardening, 7694.

Itea, peren. monog. and saxifragae, a H. tr. N. Amer. which thrive well in sandy land, and is increased by layers.

Iva, syngen. polyg. neces, and corymbiferae, S. an. and H. tr. Amer. both of common culture.

Ivy, syngen. polyg. neces, and corymbiferae, S. tr. and H. tr. Amer.

Jasminum, syngen. monog. and irideae, G. peren. and an. 3 C. B.S. bulbs which grow best in sandy loam and decayed leaves or peat, and require no water after they have been planted in well in the open garden treated in the same manner as ranunculus, guarding against frost and heavy rains.

Ixia, syngen. polyg. equal and corymbiferae, a G. tr. N. Holl. which thrives best in sandy land and peat, and young cuttings root freely in the same.

Ixora, tetran. monog. and rubiaceae, S. tr. and H. tr. and China, of great beauty, which thrive well in land and peat, and cuttings root freely in sand under a hand-glass.

Jac. ia, Icones plantarum rariores. Edita a N. J. Jacquin.

Jac. vind, N. J. Jacquin Hortus botanicus vindobonensis.

Jackant, artocarpus integrifolia.

Jack-in-a-box, hernandiaceae.

Jasminum, monog. and caprifoliaceae, G. tr. and H. peren. which grow in sandy land and peat, and young cuttings may be rooted in sand under a bell-glass, or ripened ones under a hand-glass.

Jacob, R., his works on gardening, page 1125, A.D. 1797.

Jacobisdahl, a seat in Sweden, 248.

Jacquetia, syngen. polyanthaceae, G. tr. and H. peren. which grow in sandy land and peat, and cuttings root readily in sand under a hand-glass.

Jacob, R., his works on gardening, page 1125, A.D. 1797.

Jalap, ipomea jalapa.

Jamaica, botanic garden of, 499.

Jambos, peren. and onagraceae, a S. tr. which grows in light land, and cuttings root freely in sand under a hand-glass.

Japan, gardens of, 458.

Jardin electoral de Saxe, at Warsaw, 281.

Jardin des Plantes, at Paris, described, 7331.

Jasione, sheep's scabious, peren. monog. and camp. alpineae, G. tr. and H. peren. and an. Eur. which do well in common soil, or in pots (being rather tender of frost), and are increased by cuttings or seeds.

Jasmine, — see Jasminum.

Jasminum, diaec. monog. and jasminae, S. and G. tr. E. Ind. and C. B.S. chiefly climbers, which grow in sandy land and peat, and cuttings root readily in sand under a hand-glass in heat; the H. tr. Eur. grow in common soil, and are increased by layers or cuttings.

Jatropha, sepia, monog. and euphorbiaceae, S. tr. peren. and an. W. Ind. which thrive well in loamy soil, and cuttings root best stuck in the tan and in heat.

Jauwne, St. Hilaire, his works on gardening, page 1121, A.D. 1803.

Jauwne, T. — P., his works on gardening, page 1122, A.D. 1816.

Jeffersonia, octan. monog. and papaveraceae, a H. peren. N. Amer. which grows best in peat, and is increased by seeds or dividing at the root.

Jec et d'eau, spout or fountain of water, 1892.

Jock's ledge nursery, Midlothian, 7618.

Johnston, John F., his work on the vine, page 1131, A.D. 1787.

Johnston, Thomas, M.D., his work on gardening, page 1099, A.D. 1829.

Jones, Henry, his poem on gardening, page 1107, A.D. 1796.

Jotussia, heptan. monog. and unto a., a S. tr. E. Ind. which grows freely in light loam, and large cuttings root well in sand under a hand-glass.

Jordens, J. H., his works on gardening, page 1126, A.D. 1798.

Journeymen gardeners, 7380.

Juglans, walnut, monog. polyan. and terebinthaceae, H. tr. C. Amer. increased by layers or seeds, and some kindly budding and inarching.

Juglans regia, the common walnut; as a fruit-tree, 4737; as a forest-tree, 7696.

Julien, A., his work on gardening, page 1122, A.D. 1816.

Juncus, rush, hexan. monog. and juncaceae, H. peren. Brit. grows well in general marsh plants.

Juniperus, diaec. monog. and conifereae, F. and H. tr. Eur. and Amer. the more delicate species prefer peat soil and but the cedars and savin grow in common earth; they are best managed by seeds, but cuttings may be rooted under a hand-glass.

Justicia, Bernard de, his works on gardening, page 1117, A.D. 1735.

Justicia, decan. monog. and onagraceae, S. and G. peren. and bien. Ind. and Amer. chiefly aquatics of common culture.

Justice, James, Esq. F. R. S., his works on gardening, page 1104, A.D. 1753.

Justice, diaec. monog. and achenaceae, S. and G. tr. and an. Ind. and Amer. of easy culture in land and peat, and cuttings root freely in heat under a hand-glass.
K.
Kämpferia, galangale, dian. monog. and scitami-
nea, S. peren. E. Ind. which grow freely in rich
light soil, requiring little water when not in a
growing state, and are increased by dividing at

Kimbina, morsol. polyan. and malaceae, a H. peren.
Hungary, of easy culture, and very prolific in
seeds.
Kitchen-garden, formation of, 2381.
Kitchen-garden, its culture and management, 2545 ;
culture of the soil, manure, recent dung, crop-
ging, rotation of crops, thinning, thinning stone-
fruits, pruning and training, summer pruning,
winter pruning, pruning edgings and hedges,
weeding, stirring the soil, protecting, supporting,
sheltering, and fertilising, propagation, and inci-
idents, accidents, gathering and preserving vegetables,
and sending them to a distance, proportioning
the quantity of vegetables to be grown, miscella-
neous operations of culture and management,
2546 to 2612.
Kitchen-garden, situation, exposure and aspect,
extent, shelter and shade, soil, water, form, walls,
aspect of walls, height of walls, construction of
walls, materials of walls, open railings instead of
walls, hot or flued walls, cross-walls, of coloring
walls, of glass, placing the culinary hot-houses and
melony, situation of the melony, laying out the
area, laying out the compartments, making the
boundaries, laying out the walls, laying out the
slips, laying out a nursery, or reserve department,
season for forming a garden, distribution of fruit-
trees, selection and arrangement of wall trees,
sorting the product, and arrangement of espaliers and
dwarf standards, of dwarf standards, distances of
tall standard fruit-trees, fruit-shrubs, choice of
plants, record of sorts, 2592 to 2596.
Kleinia, dioec., monog. and malaceae, a S. tr.
Ind. which grows in light loamy soil, and cut-
tings are not difficult to root under a hand-glass in
seeds.
Kleinia, syngen. polyp. equal. and corymbifereae,
a S. an. Amer. of easy culture.

Labels for naming plants, different kinds of, 1385.
Labore, Alexander, Count de, his works on gar-
dening, page 1121. A. D. 1814.
Labore's cottage and garden, what they ought to
Laburnum, — see Cytisus.
Labyrinth, a convoluted, plicated, or otherwise
retortating, distorting, disposition of walls, separated
by hedges or shrubbery, sometimes called a wil-
derness, 7204.
Lachenalia, hexan. monog. and asphodelaceae, G.
peren. C. B. S. bulbs, which thrive well in loam
peat, or loam and leaf-mould, and are in-
creased by offsets or seeds.
loam and peat, and ripened cuttings in sand under a hand-glass, root freely.

Lycopus, club-moss, cryptog. stachyophytides, and young shoots. E. Amer.

Lychnis, other bot-, plants, which grow in peat soil in pots placed in pans of water, and are increased by suckers or cuttings.

Lycopsis, wild bugloss, pantan. monog. and bora
gineae, H. peren. and an. Eur. of common culture.

Lycopus, water-horehound, diam. monog. and labia
ter, H. peren. of common culture.

Lyndey Park, Gloucestershire, 7565.

Lygeum, trian. monog. and gramineae, a H. peren.

Spain, a grass of easy culture.

Lygodium, snake’s tongue, cryptog. selismito
terides and filiceae, H. peren. E. Ind. a climbing fern, which grows freely in loam and peat, and may be increased by dividing at the root or by seeds.

Lyme Hall, Cheshire, 7590.

Lyon, Peter, his writings on gardening, page 1114.

A. D. 1815.

Lyssimachia, loose-strife, pantan. monog. and pri
mulaceae, H. peren. bien. and an. Eur. and Amer.

most of them marsh plants, some trailers or creepers of defence, 1472; care, bird-trap, bird-net, mouse-trap, garden rat-trap, mole-trap, cat
gig and beetle, wasp and fly-trap, man and traps, hunting trap, flog-trap, flog-gun, concealed alarum, common gun or musket (from mangon, a warlike machine, used before the invention of fire-arms, or musquet, from mousquet, Fr.), fumigating bello

machines.

Machines, 1449; common wheelbarrow, separating barrow, new ground-work barrow, water-barrow, hand-barrow, barn watering-engine, curved barrel-engine, self-acting green-house engine, roller, carriage water-barrel, water
ging-roller, hand-spokes, common garden-ladder, rull
d jointed ladder, step-ladder, wheel-platform, boat-axtyle, grindstone, tree-transplanter, German devil, hydrostatic prcss, seed-separator, 1441, to 1471.

Macrones used in gardening, 1439.

M'Cohon, 1131.

M'Phail, James, his works on gardening, page 1110.

A. D. 1794.

Macrospermum, pentag. monog. and rubiaeae, a S. tr.

jaica, which grows in loam and peat, and strikes by cuttings freely.

Macropodium, tetral., silic, and crucifereae, a H. peren. which grows in loam, rich, and long, and cuttings root freely under a hand-glass.

Madder, see Rubia.

Macleod, James, his work on gardening, page 1110.

A. D. 1792.

Maddo, syngia, polyg. super. and corymbiferace, a H. an Chilli, of common culture.

Mailegley, a seat in Cambridgeshire, 7551.

Madresfield, a seat in Worcestershire, 7566.

Madwurt, — see Alysum.

Malessa, a seat in Radnorshire, 7610.

Maillusionis, and magnoliaceae, G. and H. tr.

Amer. which require a pent soil and a moist situ

ation, and are generally increased by layers or seeds; the leaves are large, and must not be cut off when the leaves are removed from the stools, 7517.

Mahernia, pantan. pentan. and tallieae, G. tr.

C.B.S. which grow in loam and peat, and young cuttings taken off at a joint, and planted under a hand
glass, in the same soil, readily strike root.

Mahogany, — see Swietenia.

Maiden-hair, — see Ceterach.

Maiden-nut, justicia malabarcica.

Maiella, — see Comocladia.

Malabar night-shade, — see Basella.

Malachra, monadel. polyan. and malvacceae, a S. an.

era, of common culture.

Malaxis, gynan. monan. and orchideae, H. peren.

Eng. and N. Amer. which grow in sandy loam and peat, and are increased by offsets from the roots or seeds.

Malay apple, euagina malaccensis, 5986.

Malcolmia, tetrad. silic. and cruciferaceae, H. an.

Aur. and Afr. of common culture.

Malted, Robert, his works on gardening, page 1119.

A. D. 1775.

Mallow, — see Malva.

M all, — see M a l la.

Mannetby, James, his work on gardening, page 1192.

A. D. 1815.

Maloape, monad. polyan. and malvacceae, a G. bien.

and an. Barb. of easy culture.

Malpighia, malpighiaceae, decan. trig. and mal
pighiaceae, a S. tr. W. Ind. and Amer. which grow in light loam, and ripened cuttings are not dif
cult to root under a hand-glass in sand.

Malt, — see Swietenia.

Malva, mallow, monad. polyan. and malvacceae, G.

tr. Eur. As. Afr. and H. an. and bien. Eur. which succeed in sandy loam, rich soil, and cuttings root freely under a bell-glass in sand, or under a hand
glass in any light soil; seeds are also frequently produced.

Manninae, mameese-tree, polyan. monog. and gut
tifereae, a S. tr. Amer. the mameese-tree, 5198.

Manninea, — see M a l l a.

Management of gardens, science of, 2334.

Mammee-tree, mameese-tree, and manchee.

Mandragora, — see Mandrake.

Mandrilas, — his works on gardening, page 1118.

Mediola, hexan. trilig. and siliquaceae, a H. peren. Virginia, which succeeds best in light soil, and is increased by cuttings. - Medlow-thurt, his weighing-machine, preferable for the gardener's seed and fruit room, 1792.
Medick, - see Medicago.
Medulius, Frederick Casimir, his work on gardening, page 1124. A. D. 1782.
Medlar, - see Mespilus.
Meend Park, Herefordshire, 7508.
Molaleuca, metaseec, a H. monadelphus, with turgescence, S. and G. tr. Austral, which grow in sandy loam and peat, and ripened cuttings not too old will root in sandy loam under a bell-glass. - Melamphasia, see Melampyrum.
Melamphysa, see Melampyrum.
Melanandera, see Melanandrium.
Melanathiera, sygen. polyg. squam. and corymbifereae, a S. bien. and G. peren. Amer. which thrive well in loam and peat, and cuttings root freely under a hand-glass. - Melanthium, hexan. trilig. and melanthaceae, G. peren. C. B. S. bulbs which may be treated like ixia. - Melaphila, see Melaphila.
Melaphila, see Melaphila.
Melastoma, decan. monog. and melastomaceae, S. tr. which thrive in loam and peat, require little water in winter, and young cuttings root readily under a hand-glass in moist heat.
Melburn, a seat in Yorkshire, 7582.
Melchett Park, Wiltshire, 7596.
Melianthus, podophyllum, and malvaeeae, S. tr. St. Helena, which grow freely in sandy loam and cuttings root in sand under a bell-glass. - Melia, bead-tree, decan. monog. and meliaceae, a S. tr. and G. tr. and Syr. and Ind. and Syria, which grow in loam and peat, and cuttings root under a hand-glass in sand. - Melianthus, mexicana, F. and g. tr. which thrive in rich, light soil, and cuttings planted under a hand-glass will root freely.
Melic-grass, - see Melica.
Melica, trian., trian., dig. and grumineae, H. peren. and Amer. grasses of easy culture.
Meliceca, honey-berry, octan. monog. and sapindee, a S. tr. Jam. which thrives best in loam light, and cuttings root in sand under a hand-glass in heat.
Melliot, trifolium melliot.
Mellitus, melliot, diadel. decan. and leguminoseae, H. bien. and an. Eur. of easy culture, and increased by seed.
Melimula, (from nucel, honey, and meliwm, an apple), sweet acid cuttings and cuttings' root.
Melochia, monadelph, and malvaeeae, S. tr. and an. W. and E. Ind. which grow in light loam, and cuttings root under a hand-glass in heat.
Melodinus, pentan. dig. and apocyneae, a S. tr. N. Caledonia, a climber which grows freely in loam and peat, and cuttings root readily in sand under a bell-glass.
Melon, - see Cucumis.
Melon-pit, at Edstonstone, 2655.
Melon-pit, at Knight's, 2054.
Melony, 2479.
Melothria, trian. monog. and curcurbitaceae, a H. an. Amer. of common culture.
Melton on the Hill, Yorkshire, 7582.
Melfile, Castle, Middlethian, 7618.
Myrica, caulisberry-myrtle, diosc. tetr. and
aromaticae, G. tr. C. B. S. which grow in
and peat, and cuttings root freely under a.
cham. glass; the H. tr. Brit. and Amer. prefer
a moist peat soil, and are annually increased
by seeds or cuttings.
Myriophyllum, water-milfoil, monoe. polyand.
and invaded, H. peren. Brit. aquatics increased
by seeds.
Myrtillus, the nutmeg, diosc. monad. and myrtil-
seae, S. tr. Ind. which grow in light loam,
and have as yet been little propagated.
Rumex, nodular, poly. and malacaveae, S. tr. W.
Ind. which grows readily in light, rich soil,
and cuttings root readily in sand under a.
bell-glass.
Nasturtium, — see Myrrhis.
Myrrhis, myrth, pentan. dig. and umbelliferae,
H. peren. Brit. of easy culture.
Mysrlne, polyg. diosc. and myrcinaceaee, G. tr.
C. B. S. evergreens which grow in light
and peat, and cuttings root readily in sand
under a hand-glass.
Mysrilphium, hexan. trig. and smilacaceae, G. peren.
C. B. S. climbers which thrive in light
and peat, and are increased by division at
the root.
Myrryl, myrth, nicos. monong. and myrrceae, G. tr.
Eur. and W. Ind. which grow freely in rich
loam, and are increased by cuttings. Myr-
tosha requires the heat of a dry stove, and
the cuttings, which must not be too old, will
root under bell-glasses.

Nicotiana, tobacco, pentan. monong. and solanacea,
a popular and thriving cult. of H. and Amer.
and China, which thrive in any light soil, and
are readily increased by seeds.
Nigellas, fennel-flower, polyg. pentang. and ranucu-
lausceae, S. tr. Ind., which thrives best in
a warm, sunny, or myrte, of common culture.
Nigella activa and arvensis, as culinary plants, 4335.
Nightshade, — see Solanum.
Nigella sativa, — see Lapsana.
Nissolia, diadell, decan. and leguminosae, S. tr.
S. Amer. which thrives in sandy soil, and
cuttings may be rooted in sand under a
hand-glass.
Nitraria, dodoc. monong. and ficoidea, H. tr. Si-
beria, which thrives best in sandy loam, with
some soil occasionally put round it, being a salt
marsh plant; it may be increased by layers or cuttings
under a hand-glass in sand.
Nivenia, tetra, inag. and protocaceae, G. tr.
and aceraceae, which grow in soft loam, peat,
and sand, the pots well drained and placed in a
situation; ripened cuttings taken off at a joint
without shortening their leaves, will root in sand
under a hand-glass, in very cool and shady situation.
Notissae, Mons. Louis Claude, his works on gar-
Notons, monan. and boraginaceae, H. an.
Boraginaceae, of the Old World.

Oliveria, a seed, dig. and umbellifereae, a H. an. Bagdad, of common culture.
Olivu, monoca. trian. and gramineae, S. peren. W. Ind. a grass of easy culture.
Olney Court, Worcestershire, 7566.
Olmaphoe, monad. monad. and euphorbiaceae, a S. tr. Jamaica, which grows in light loam, and cuttings root in sand under a hand-glass in heat, care, but is not taken to injure the leaves.
Onicidium, gynan. monan. and orchideae, S. peren. Ind. which require the same treatment as aërids.
Onion, — see Allium.
Oniscus asellus, the wood-louse, 2473.
Onoclea, cryptog. filices and filiceae, H. peren. Eur. and Ind. of common culture.
Ononis, rest-harrow, diadel. deean. and leguminoseae, G. tr. peren. and Eur. and C. B. S. which thrive in loam and peat, and are increased by seed or young cuttings under a bell-glass in sand.
Onopordum acanthum, 3500.
Onosma, pentan. monog. and boragineae, G. peren. and Eur. S. Ind. and Br. and Eur. which are aërids, and best in rich, light soil, and are increased by cuttings under hand-glasses in sand.
Onosmodium, pentan. monogynae. and boragineae, H. peren. N. Amer. which may be treated as onosma.
Operations of gardening, 1853.; mechanical, lifting, carrying, drawing, pushing, etc. 1856. to 1861.
Operations, laborious, on the soil, 1862; picking, digging, shovelling, excavating, levelling, marking with the line, trenching, ridging, forking, hoehing, spading, scraping, swerving, wheeling, beating, rolling, sifting, &c. 1863. to 1881.
Operations, laborious, with plants, 1882; sawing, cutting, clipping, splitting, mowing, weeding, watering, and fertiliser of common culture.
Operations in which skill is more required than strength, 1884; transferring designs from ground to paper, mapping, drawing, division of designs, forms of surface, irregular figures, raised and depressed surfaces, delineating by ground-lines only, elevations, profiles, circular profiles, bird's-eye viewing, &c. 1885. to 1912.
Operations, transferring figures or designs from paper or memory to plain surfaces, 1914; perpendiculars, angles, ovals, gardener's oval, a spiral line, centre of three points, points, polygonal gardens, fanciful figures, 1915. to 1924.
Operations of gardening; transferring figures and designs to irregular surfaces, 1925; straight lines, continuous lines, curved lines, level lines, &c. 1926. to 1933.
Operations for the arrangement of quantities, by trial and observation, by rule, measure superficially, by solid measure, 1935. to 1939.
Operations for carrying designs into execution, 1940; removing surface encumbrances, smoothing surfaces, throwing off water by under-drains, by surface-drains; forming excavations for retaining water, removal of earth, forming the bed or bottom, heaping, scraping, &c. 1885. to 1912.
Operations of propagation, 1985; by seed, buds, offsets, slips, division of the plant, runners, suckers, layers, twisting, ricing, planting, and wire-layers, layering trees in the open garden, stools, Chinaceae layering, inarching, grafting,
which prefers a shady situation in a light sandy loam, is increased by seeds.

Park, in gardening, a portion of forest-like scenery attached to a country-house, and devoted to the growth of timber, the harbor of game, deer, or the grazing of cattle and glass-glass.

Park, par, J. Parkinson Paradisi in Sole, Paradisi terraestris.

Parkes, at Poole, Berkshire, 7561.

Parkinson, John, his works on gardening, page 1099. A. D. 1629.

Parkinson, decan. monog. and leguminoseae, a S. tr. Ind. which thrive in light loam and peat, and cuttings root in sand under a bell-glass.

Parkyns, G. J., his works on gardening, page 1113. A. D. 1635.

Parkias, Monog. and aramaranthaceae, G. peren. Eur. which thrive well in light and peat, and cuttings root freely under a hand-glass; the H. peren. and an. prefer the same soil, and are increased by seeds or cuttings. Parsley, 4082 — see Apium.

Parsley, par, alchemilla aphanes. Parsnip, see Pastinaca.

Parterre, the garden parsley, see Pulsatilla.

Parterre, sparrow-wort, octan. monog. and thymes, G. tr. C. B. S. which thrive best in sandy peat, and cuttings root freely under a bell-glass, in moist soil.

Passiflora, passion-flower, monadelph. pentand. and passiflora, G. and S. tr. shrubs, free growers, and thrive best in light loam and peat, and young cuttings root readily in heat under a bell-glass.

Passiflora quadrangularis, and other fruit-bearing species, 6093.

Passion-flower, — see Passiflora.

Pastinaca, parsnip, pentan. dig. and umbellifereae, H. bien. and a peren. of common culture.

Pastinaca sativa, the garden parsley, 5723.

Patte d'oie, or cross patte d'oie, (heraldry), a cross with the crozets spreading like duck feet, as in the Martello cross, — a form of planting avenues, &c., 6913.

Patersonia, monadel. trian. and irideae, G. peren.

N. S. W. which grow in loam and peat, and are increased by division at the root.

Pauiet, — his works on gardening, page 11:0. A. D. 1793.

Papilion, trifl. trig. and spinifer, S. tr. W. Ind. which succeed in light loam, and cuttings root best in sand in bottom-heat under a bell-glass.

Paulston, seat in Hampshire, 7594.

Pavetta, tetrandria monogynia and rubiaceae, a S. tr. E. Ind. which thrive best in light loam and peat, and cuttings root readily in sand under a hand-glass, in moist soil.

Pawlet, a royal residence in Brighton, 7533.

Pavonia, monadel. poly. and malvaceae, S. and G. tr. and S. an. E. and W. Ind. which grow in loose sandy loam and a peren. readily in sand and glass-glass; most of the species produce abundance of seeds.

Pawlosky, an imperial seat near Petersburgh, 258.

Peach, see Prunus.

Peach-house, its construction, 2664; general culture and management of, 2906.

Peach-gatherer, 337.

Peach-tree, — see Amygdalus.

Pear-gatherer, 1555.

Pear-tree, — see Pyrus.

Pearwort, see Socorea.

Peart-earth shrubs, their culture, final situation, 6599.

Pectis, syngen. polyan. super. and corymbebre, S. an. W. Ind. of common culture.

Pedalium, didynam, angies and pedalineae, S. an. E. Ind. of common culture

Pedicularis, lousewort, didynam. angies and scrophularineae, F. and H. peren. and an. Eur. and Amer. which succeed best in peat soil and are increased by seeds.

Peel Hall, Cheshire, 1590.

Peganum, dodec. monog. and rutaceae, H. peren. Eur. which thrive in rich, light soil, and cuttings root readily in sand under a bell-glass.

Pektro, a seat near Moskwa, 262.

Pelargonium, stork's bill, monadel. heptan. and geraniaceae, G. tr. peren. and an C. B. S. and an. S. Ind. all of garden culture in any rich, light soil, the succulent sorts well drained and not overheated, 6601.

Pelargonia, see Plantaginaceae, a French author on gardening, page 1116. A. D. 17—.

Peliosanthes, hexan. monog. and —, S. peren. E. Ind. which grow best in rich loam, and are increased by dividing at the root.

Pelleto-Saune, M. —, his work on gardening, page 1122. A. D. 1813.

Penicillaria, see Plantaginaceae.

Pellaria, tetrad. silic. and crucifereae, a H. peren.

Austral of common culture.

Pembroke house, gardens and residences of, 7599.

Peninsula, monog. and jasmine, G. tr. C. B. S. which thrive in loam and peat, with the pots well drained, and young cuttings root without difficulty under bell-glasses in sand.

Penrhyn Castle, a seat near Carnwath, 7511.

Penguern, a seat in Flintshire, 7506.

Penicillaria, poly. monog. and crucifereae, a S. and E. Ind. an. E. and W. Ind. of common culture.

Penicillaria, trinog. angies and crucifereae, a H. Eur. and Ind. grasses of the easiest culture.

Penny-cuck Hill, Midlothian, 7518.

Pennyroyal, montana purgativum, — see Mentha.

Pennywort, — see Hydrocotyle.

Penpont, a seat in Breconshire, 7513.

Pennylawn Castle, Caernarvonshire, 7504.

Penrice Castle, Glamorganshire, 7508.

Penshurst, a seat in Kent, 7538.

Pentapetes, monadel. dodec. and malvaceae, a S. tr. and a bien. Ind. and N. Spain, which grow freely in light rich soil, and cuttings root in sand under a bell-glass.

Penthomur, decan. pentag. and sempervireae, a F. tr. in Hisp. which grows freely in light, sandy soil, and is readily increased by dividing at the root, or by young cuttings under a hand-glass.

Penttr-gland, a seat in Pembroke-shire, 7509.

Pentstemon, didynam. angios. and bignoniaceae, a F. tr. and H. peren. N. Amer. which grow in light rich soil, and succeed well in pots. Cuttings root freely under hand-glasses.

Pentzia, syngen. polyan. aequal. and corymbebre, a G. tr. C. B. S. which thrive well in any rich, light soil, and cuttings root freely under a hand-glass.

Peplis, water-purslane, hexan. monog. and salicornieae, a H. an. Brit. a marsh plant of easy culture.

Pepper, — see Piper.

Pepper Harrow, a seat in Surrey, 7292.

Peperomia, cissus stans.

Pepperwort, — see Lepidium.

Peregrina, syngen. polyan. super. and corymbifereae, a H. peren. Siberia, which grows in rich light soil, and is increased by dividing at the root.

Perfect, Thomas, his works on gardening, page 1103. A. D. 1759.

Perforated piers, piers for fruit-tree walls, the project which are perforated to admit of training the shoots through the pier, instead of stopping them there, or bending them over it. It is commonly done with a lattice-like, but the rounded pier (1572, fig. 246, a), where practicable, is to be preferred, as more readily admitting the taking down and replacing of the branches at the pruning times.

Pergularia, pentan. dig. and asclepiadaceae, S. tr. E. Ind. fragrant climbers which succeed well in loose sandy loam, and cuttings root readily in sand under a hand-glass.

Perilla, didynam. gymnosoph. and labiateae, a H. an. India, of common culture.

Persicaria, didynam. angies and asclepiadaceae, a G. and H. tr. Syria and the Canaries, which grow freely in common soil, and are increased by layers or cuttings.

Perswinkle, — see Vinca.

Petrosia, trian. dig. and gramineaee, a S. an. E. Ind. of common culture.

Parsley, polygonum persicaria.

Persicaria, tetran. monog. and proteaceas, G. tr. N. S. W. which thrive in loam and peat, and ripened cuttings root in sand under a hand-glass.

Perth nursery, 7653.

Peterson, the gardens and residences of, 7653.

Petchelins, his works on gardening, page 1123.

A. D. 1597.

Petalostenum, diadel. pentan. and leguminoseas, F. tr. N. Amer. which thrive in light, rich soil, and are increased by seeds or dividing at the root.

Peterhoff, an imperial residence near Petersburgh, 254.

Peterkin, Joshua, his works on planting, page 1131.

A. D. 1799.

Peterkin, Richard, his work on gardening, page 1151.

A. D. 1810.

Petersham Lodge, Surrey, 7367.

Petcas, her heptan. and chenopodoseas, S. tr. W. Ind. which grow well in light, rich soil, and cuttings root freely under a hand-glass.

Petraea, Petre, Pentan. dig. and rubicaseas, A. tr. and an. chiefly W. Ind. which succeed well in loam and peat, and cuttings root freely in soil under a bell-glass.

Petrie, Robert, Lord, an accomplished nobleman and an encourager of gardening in the time of Miller, — see Ingatestone.

Petrocallis, tetrad. silic. and cruciferoseas, A. peren. Petroselinum, rock-plant, which grows well in peat, and cuttings root readily under a hand-glass.

Petrophila, tetran. monog. and proteaceas, G. tr. N. S. W. which make good protoces. Petrows, a seat near Moskwa, 261.

Petworth House, Sussex, 7352.

Phaca, bastard vetch, diadelp. deca. and leguminooseas, H. peren. which succeed in common garden soil, and are increased by seeds. Some of the dwarfer kinds are well adapted for rockwork or growing in pots.

Phalaenopsis, the orchid, 7075.

Phasma, pearson's, the morel, 4542.

Pharus, monoc. hexan. and gramineae, A. peren. Jam, a grass of easy culture.

Phaseolus, kidney-bean, diadelp. deca. and leguminooseas, S. peren. and an. and H. S. Asia, Amer. and Africa, which thrive in light, rich soil, and are readily propagated from cuttings or seeds.

Phaseolus vulgaris, the common kidneybean, 3529; to force kidneybeans, 3587; soil, sorts, sowing, culture, time of beginning to force, temperature, successional supplies, forcing in a hot-house, insects, forcing in a peach or cherry house, in a common hot-bed, crop raised under glass to fruit in the open garden, crop raised on slight heat, 3588 to 3590.

Phessiany, 7347.

Phellandrum, water-hemlock, pentan. digyn. and umbellaceseas, A. tr. and H. peren. which thrive in sandy loam and peat, and cuttings root under a hand-glass; aquatic which may be sown in pots and placed in the aquarium, or the seeds scattered in any pond.

Phillips, Henry, his works on gardening, page 1114.

A. D. 1600.

Phl. Leonardin, jun., nurseryman, his works on gardening, page 1114. A. D. 1814.

Phlioxerus, pentan. monog. and amaranthaceas, A. tr. and peren. Amer. which thrive well in rich soil, and are increased by cuttings or dividing by cuttings.

Philyrhum, dian. monog. and junecas, A. tr. China, of common culture.

Phyloca, helianthus.

Phlomis, digyn. gymnos. and labiateae, H. tr. and peren. Eur. which prefer a light, dry soil, and are increased by cuttings under a hand-glass or on peat.

Phlox, lychnidea, pent. monog. and polemaceae, H. peren. Amer. mostly border-flowers, which prefer a rich loam, and are increased by cuttings or dividing at the roots.

Phoenix, palm, dian. trian. and palmaceas, A. tr. and G. tr. Levant, C. B. S. and E. Ind. which require a light soil, and are increased by seeds.

Phoenix Park, Dublin, 7653.

Phormium, monog. and asphodeleeas, A. peren. and S. peren. E. Ind. which thrive in rich, light soil, and are increased by seeds or cuttings root readily in sandy peat.

Physicea, pentandria monogynia and rhannacea, G. tr. C. B. S. which grow best in sandy peat, and young cuttings root readily under a bell-glass in sand.

Phyllanthus, monoece, monad. and euphorbiaceeas, S. tr. and an. chiefly W. Ind. which succeed well in loam and peat, and cuttings root freely in soil under a bell-glass.

Phyllis, pentan. dig. and rubicaseas, G. tr. Canar. which grow in loam, and cuttings root well in a hand-glass.

Phyllomea, hexan. monog. and asphodeleseas, A. tr. Bourb, which thrive well in sandy loam, requires very little water, and is increased by suckers.

Phys. des Arb., Duhamel sur le Physique des Arbres.

Physalis, winter cherry, pentan. monog. and solaneae, S. and G. tr. and H. peren. and an. chiefly N. Amer. which thrive well in rich, light soil, and are increased by young cuttings under a hand-glass or by seeds.

Physic-gardeners, herbalists, or simplicists, 7464.

Physic-nut, — see Jatropha.

Physic or herb gardens, their formation, 7390.

Pinecea, rampon, pentan. monog. and campaceseas, C. Pers. the eucalyptus, H. peren. and a British chiefly Europe, which thrive in rich, light soil, do well in pots, and are increased by dividing at the root; the garden rampon is a campanula.

Phytolaccea, dodec. decac. and chenopodoseas, A. tr. As. Afr. and Amer. which thrive well in loam and peat, and are increased by cuttings or seeds.

Paranthema, pentan. monog. and asclepiaceas, A. D. S. tr. C. B. S. a succulent which grows in loamy soil with old lime rubbish, and sand well drained by being mentally increased by cuttings.

Picciuoli, Giuseppe, his work on gardening, page 1128. A. D. 1783.

Pick and pick-axe, 1296.

Picking, 1295.

Picramnia, dioec. pentan. and ............... , A. tr. Jam, which thrives in loamy soil, and large cuttings thrive very luxuriantly in a hand-glass.

Pierolium, syngen. polyg. aequal. and cichoreaceas, A. peren. and an. France and Barb, of common culture.

Pieris, syngen. polyg. aequal. and cichoreaceas, H. peren. and an. chiefly Europ of common culture.

Pieris hieracioides, hawkweed-like, ox-tongue, 4591.

Picton, a seat in Pembroksire, 7099.

Pierard, Charles Francis, his work on gardening, page 1140. H. peren. and an. 1812.

Piercefield, a seat in Monmouthshire, 7557.

Pierre, Louis de, his works on gardening, page 1108.

A. D. 1772.

Pigeon-house, — see Columbarium.

Pigeon-houses of Persia, 463.

Pigott, Richard, his work on gardening, page 1114.

A. D. 1600.

Pilowell House, Hampshire, 7904.

Pliewort, ficaria verna.

Plillowort, pilularia globulifera.

Pilularia, dig. hydropter. and mariseaceas, A. peren. Brit. an aquatic of common culture.

Pimmel, dian. monog. and thymeleas, G. tr. Aust. which thrive best in sandy peat, and young cuttings root in sand under a bell-glass.

Pimpernell, — see Anagallis.

Pinnulina, burnet-xaxfadreg, pentan. digyn. and um-
belfferet, H. peren. and an an. chiefly Europ., which grow in rich, light soil, and are increased by seedlings.
Pimpinella anisum, the anise, 4219.
Pimpinella, pan ten, monog. and rubescens, a P. tr. Geraniaceae, which grow in sandy and peat, and cuttings root in sand under a glass-hind.
Pinnaceim, Ippolito, his works on gardening, page 1199, A. D. 1817.
Pine-apple, 214, see Bremia.
Pine-tree, — see Ficus.
Pinery, its construction, 2645; general culture and management, 2297.
Pimpernel, a butterwort, dian. monogyn. and lenticularis, a G. an. Carolin. and H. peren. Europ., which grow naturally in swamps, and succeed in any of any species of aquatic plants. A little peat at the bottom, like drosa: they are increased by offsets from the heart of the plant, and from seed.
Pimpinella vulgaris, the common butterwort, 4320.
Pink, — see Dianthus.
Pinkle House, East Lothian, 7618.
Pinet, the pine-fir and larch, monod. monand. and coniferous, a S. tr. Ambuaya, G. tr. E. Ind. and H. tr. Eur. and Amer.; the S. species succeed in light, loamy soil, and ripened cuttings taken off at a joint will root, though not readily, in sand under a glass-hind; the G. species require the same soil, and roots more freely; the H. species grow in light soil, and are commonly increased by cuttings.
Pinus abies, the spruce-fir, and other firs in common cultivation, 7058, to 7067.
Pinus cedrus, and P. caralis, the cedar-larch, and common larch, 7051, and 7053.
Pinus sylvestris, the Scotch or wild pine, and the other pines in common cultivation, 7051, and 7055.
Pipewort, a P. tr. chiefly climbers, peren. and an. W. Ind. mostly succulent plants which grow in sandy loam and peat, and are readily increased by cuttings and suckers.
Pipewort, eriocaulon septangulare.
Piqueria, syngen. polyg. ascal. and corymbiferre, a G. peren. Mex. which grows freely in any light, rich soil, and cuttings root readily under a glass-hind.
Piscidia, Jamaica dogwood, diadel. decan. and leguminosea, a S. tr. W. Ind. A strong fast-growing plant in sandy loam, and cuttings root in sand under a glass-hind.
Piscinaria, 1707.
Poé, or en pié, (en pire or en pien), in the worst manner, that is, as a last resource, a mode of building mud walls, 1594.
Pisania, heptan. monog. and nyctagineae, a S. tr. V. Ind. and a G. tr. Austral which grow in loam and peat, and cuttings root in sand under a glass-hind.
Pistacia-tree, — see Pistacia.
Pistacia, dioec. pentag. and trebiineactae, G. tr. Barb. and H. tr. S. Eur. the G. species grow in loam and peat, and ripened cuttings root in sand under a glass-hind; the H. tr. are rather tender, but grow in common soil, and are increased by layers or cuttings under a glass-hind in sandy soil.
Pisum sativum, the sea-pea, 4309.
Platum sativum, the garden-pea, 3397; to force the pea, 3393.
Pitch, a mixture with a glass cover or roof, used as a habitation for plants. Earth-pit, bvrk-pit, fluxed pit, M'Phail's pit, Alderstone pit, pit with rising frame, West's pit, &c. 1540. to 1544.
Pitch, in the conservatory, the bed of earth in which the trees are planted, occupying the principal part of the area of the house.
Pitch of a flower hot-house, an excavation in the middle or bark-stove for containing fermentable materials in order to supply bottom heat.
Pitcairnia, hexan. monog. and bromeeae, S. tr. W. Ind. an. shrub, a flower freely in light, rich soil, and are increased by suckers from the root.
Pitcher-plant, nepenthes distillatoria, 593.
Pitcoutist, a seat near Worcester, 3329.
Plants-tree, — see Platanus.
Plank-plant, bosseia seolopendium.
Plank-plant, a maker of plans, — see Horticultur-}
Architect.
Plants for improving country-residences, 7304; how to increase, 7304; important uses of, 7308; how to carry into execution, 7370.
Plants of gardens and garden objects, how to form, 1855; to transfer them to ground, 1913; to execute, 1914.
Plantago, a hooking-caul, different sorts of, 1404.
Plantaginaceae, a G. tr. and bien. C. B. S. and H. peren. and an. chiefly Eur. all of very easy culture in common soil.
Plantago coroneus, star of the earth, 4315.
Plantain, — see Plantago.
Plantain-tree, — see Musa.
Platonic, neglected, to improve, neglected hedge-
rows, hedge-row timber, neglected ornamental plantations, 6914. to 6924.
Plantations, ornamental, their formation, 6832; form, extent, disposition, general form, situation, arrangement of species, size of plants, 6533. to 6576.
Plantations of trees, their uses, as to shelter and climate, improving soils, shade, separation, scel-}
Union, distinction, appropriation, concealment, to}
help the growth of humble objects, direct the eye to ob-
jects, render indiffernt objects agreeable, en-
hance the value of landed property, afford profit, 6702. to 6772.
Plantations of their different kinds, group, clump, woods, cosseoppe, 6810. to 6814.
Plantations, their disposition in the ancient style, 6915; in the modern style, 7214.
Plantings, in garden and in field, 6815; prepar-
ing the soil, form, enclosing, fences, species of tree, mixture, whether to be sown or planted, disposition of the plants, number of plants and size, distance of the plants, seasons for planting, operations of, 6816. to 6851.
Plantations, useful and ornamental, their culture and improvement, 6852; culture of the soil, fill-
ing up blanks, pruning, for utility, for ornament, seasons for, implements for, resinoses trees, non-
resinous trees, and shade-trees, pruning for, for
bends, coppices, osier huts, strips and screens, trees for shade, trees in parks, in pleasure-grounds and lawns, thinning, 6875. to 6913.
Plantations, valuation of, 6996.
Planting, — see Arboriculture.
Planting, different modes of performing the oper-
at, 977. 2108.
Planting in arboriculture, operation of, by pitying, by the diamond dibber, by the planter's mattock, by the planter, by slitting, 6841. to 6851.
Plants, vegetable, 6805.
Plants, as indicative of soils, list of, 1036.
Plants used as preserves and pickles, 4258.
Plants used in tarts, confectionary, and domestic medicine, neglected, 6805.
Plas Newydd, a seat in Anglesea, 7603.
Plat (plat, Fr. flat), a piece of ground of determinate form, compared with a field, but larger than a border, bed, or stripe, — see Plot.
Plat-band (plat bande, Fr.), a border a round flat.
Platanus, plane-tree, monoc. polyan. and amenist-
see, H. tr. Levant, and N. Amer. handsome tim-
ber trees which grow in common soil, and are propagated by layers or cuttings.
Platt, Sir Hugh, his works on gardening, page 1069. A. D. 1394.
Platts, Gabriel, his works on gardening, page 1100.
Platt, A. D. 1603.
Platylobium, flat pea, diadel. decan. and leguminosea,
G. tr. Austral. which grow in sandy loam and peat, and cuttings root in sand under a glass-hind.
Plaz, Anthony William, his works on gardening, page 1120. A. D. 1764.
Plaza, Anthony William, to plait or weave, an arbora-
maker, — see Topiarius.
Pleasure-ground, garden-scenery devoted to show and reception generally placed near the house, and consisting of lawns, shrubbery, flower-gardens, walks, water, seats, &c.
Pleuranthus, didym. gymnos. and labiacete, a S. tr. and, an. and G. tr. and a bien. Africa and E. Ind. of easy culture in light soil.
Potentilla anserina, the wild tansy or goose-grass, 4307.
Poterium sanguisorba, the common burnet, 4072.
Pothis, tetran. monog. and alioideae, S. peren. W. Ind. and H. peren. N. Amer. of all kinds thrive well in loamy soil, and are increased by dividing the roots, or by seed.
Potsdam, gardens of, 188.
Powderham Castle, Devonshire, 7600.
Powell, Anthony, Esq. his work on gardening, page 1107. A.D. 1769.
Powys Castle, a seat in Wicklow, 7654.
Poynton, a seat in Cheshire, 7590.
Pradis, dianem. gymnos. and labiatae, F. tr. S. Eur.

**Plants which thrive in light rich soil, and are increased by dividing the roots, or by seed.**
Primula, primrose, 324.
Primrose, 29.
Primula, alpines, 9603.
Primula, a species which grows best in light sandy soil, and may be increased by division of the root.
Primula, auricula, the auricula, 6339.
Primula, elatior, the oxlip, 6403.
Primula, veris, the cowslip, 6401.
Primula vulgaris, the primrose, 6392.
Primula vulgaris, var. polyanthus, the polyanthus, 6389.
Prince's feather, amaranthus hypochondriacus.
Princes, equestrian, pedestrain, and towers, G. tr. A. Eur.

**Plants which grow in loamy soil in shaded situations, and the alpines thrive best in peat and loam in pots; all require to be frequently parted and replanted.**
Primula auricula, the auricula, 6339.
Primula elatior, the oxlip, 6403.
Primula veris, the cowslip, 6401.
Primula vulgaris, the primrose, 6392.
Primula vulgaris, var. polyanthus, the polyanthus, 6389.
Prince's feather, amaranthus hypochondriacus.

**Plants which thrive in light loamy soil, and cuttings not deprived of their leaves, root in peat; and if increased by cuttings in sand under a bell-glass, or by seeds, which they ripen abundantly.**
Primula auricula, the auricula, 6339.

**Plants which thrive well in light loam, and cuttings not deprived of their leaves, root freely in sand; and if increased by cuttings in sand under a bell-glass, or by seeds, which they ripen abundantly.**
Primula auricula, the auricula, 6339.

**Plants which thrive in a sand and peat mixture, and cuttings root readily under a bell-glass.**
Prunus, dianem. monog. and rosaceae, S. peren. W. Ind. and H. peren. Brit. and N. Amer. of all kinds thrive well in light sandy soil and may be increased by division of the root.
Prunus, dianem. monog. and rosaceae, S. tr. A. Eur. and H. peren. and var. in England, for their fruit; here they thrive best in loam and peat, and ripen freely readily; they are increased by cuttings in sand under a bell-glass, or in a loam and peat mixture.

**Plants which grow in loam and peat, and cuttings root readily under a bell-glass.**
Prunus, dianem. monog. and rosaceae, S. tr. W. Ind. which grows freely in loam and peat, and are increased by cuttings in sand under a bell-glass, or by seeds, which they ripen abundantly.
Prunus, dianem. monog. and rosaceae, S. tr. W. Ind. which grow in loam and peat, and cuttings root in sand under a bell-glass.
Prunus spinosa, the sloe, 4765; P. padus, the bird-cherry, 4795.
Priside, syngyn. poly. necessa. and cortybfyrene, a S. tr. Maurit. which grows freely in rich light soil, and cuttings will root readily under a bell-glass.
Priside, guava, icos. monog. and myrtaceae, S. tr. W. Ind. which thrives best in loam or sand, and ripen freely readily; they are increased by cuttings in sand under a bell-glass, or in a loam and peat mixture.
Priside, ptyyonrema, the ptyyonrema, 5982.
Priside, lycopylene, the lycopylene, S. peren. W. Ind. a fern which grows in loam and peat, and cuttings will root under a sand-glass in sand.
Priside, diadeiph. decan. and leguminoseae, S. bien. and G. tr. and peren. chiefly C. B. S. which grow freely in loam and peat, and are increased by cuttings in sand under a bell-glass, or by seeds, which they ripen abundantly.
Priside, a species which grows freely in loam and peat, and cuttings root freely under a bell-glass.
Priside, a species which grows freely in loam and peat, and cuttings not deprived of their leaves, root freely in sand; and if increased by cuttings in sand under a bell-glass, or by seeds, which they ripen abundantly.

**Plants which thrive in sandy loam and peat, without much water after it has done flower and fruit.**
Priside, a species which grows freely in loam and peat, and cuttings root readily under a bell-glass.
Priside, a species which grows freely in loam and peat, and cuttings not deprived of their leaves, root freely in sand; and if increased by cuttings in sand under a bell-glass, or by seeds, which they ripen abundantly.

**Plants which grow in loam and peat, and cuttings root readily under a bell-glass.**
Primula auricula, the auricula, 6339.
Primula elatior, the oxlip, 6403.
Primula veris, the cowslip, 6401.
Primula vulgaris, the primrose, 6392.
Primula vulgaris, var. polyanthus, the polyanthus, 6389.
Prince's feather, amaranthus hypochondriacus.

**Plants which grow in loamy soil in shaded situations, and the alpines thrive best in peat and loam in pots; all require to be frequently parted and replanted.**
Primula auricula, the auricula, 6339.
Primula elatior, the oxlip, 6403.
Primula veris, the cowslip, 6401.
Primula vulgaris, the primrose, 6392.
Primula vulgaris, var. polyanthus, the polyanthus, 6389.
Prince's feather, amaranthus hypochondriacus.
Primula auricula, the auricula, 6339.
Primula elatior, the oxlip, 6403.
Primula veris, the cowslip, 6401.
Primula vulgaris, the primrose, 6392.
Primula vulgaris, var. polyanthus, the polyanthus, 6389.

cynarocapheae, H. peren. Eur. of common culture.

Serruria, tetran. monog. and proteaceae, G. tr. and a H. C. B. S. free. drawers which require the same treatment as protea.

Sersalisia, pentan. monog. and sapotea, a G. tr. N. Hoff. which grows in sandy soil and peat, and cuttings root readily in sand under a hand-glass.

Service-tree, — see Pyrus.

Sesamum, cary. grains, diyn. angios. and bignoniae, S. an. of easy culture.

Sobanja, diadel. decor. and leguminosae, a S. tr. bien. and an. E. Ind. of common culture. The is a species of a beautiful plant.

Seseli, medow-saxifrage, pentan. dig. and umbellifere, H. peren. bien. and an. Eur. and N. Amer. of common culture.

Seleria, trian. monog. and gramineae, H. peren. of easy culture.

Sesuvium, iocos. di-pentag. and ficoideae, S. peren. and an. W. Ind. and S. Amer. succulent which grow in loam and peat, and are easily propagated.

Shade, in arbiculture, 6763.

Shewing the allain. ascension, — see Allium.

Shanbally, a seat in Tipperary, 7697.

Shane’s Castle, a seat in Antrim, 7684.

Shardeles, a seat in Buckinghamshire, 7547.

Shardock, Robert, L.L. his works on gardening, page 1100. A.D. 1690.

Shawe, James, his work on gardening, page 1111. A.D. 1754.

Shaw, William, his work on gardening, page 1113. A.D. 1807.

Shaw Park, a seat in Clackmamnan, 7633.

Sheep’s beard, — see Arnopogon.

Sheep’s scabions, — see Jasion.

Sheffield Place, Sussex, 7533.

Shelter, in arbiculture, 5782.

Shepherd’s club, verbasum thapsus.

Shepherd’s purse, thalspi bursa pastoris.

Sherborne Castle, Dorsetshire, 7588.

Sherborne House, Gloucestershire, 7565.

Sherborne Castle, Oxfordshire, 7538.

Sherwood Lodge, Surrey, 7527.

Sheet or swathing, or covering with a Scotch term for the operation of carthing in, or laying in plants by the heels, for temporary purposes.

Shield.farm, — see Allium.

Shifting, the transplanting of plants in pots, different methods of performing, 2104.

Shincliffe Hall, Durham, 7584.

Shipley, a seat in Derbyshire, 7574.

Shobdon Court, Herefordshire, 7568.

Shore-weed, litorrella lascrulis.

Short-grove, Essex, 7542.

Shovel, 1301.

Shovelling, 1836.

Shrub Hill, Surrey, 7527.

Shrubbery, forming the, 6130; situation, soil, walks, fence, reserve-ground, 6131 to 6137.

Shrubbery, planting of, 6138; in the mingled manner, select manner, systematic manner, general purpose, fruit-trees in shrubberies, decorations, 6135 to 6160.

Shrubbery, its culture and management, 6181; times of planting and sowing, pruning, training, and dressing glass plots, protecting water, insects, 6183 to 6200.

Shrubbery, considered in respect to landscape-gardening, 6850.

Shrubby trefoil, petlea trifoliata.

Shrubs, ornamental, select, deciduous, evergreen, climbing, selection for particular purposes, for concealing vertical and horizontal defects, of rapid and bulky growth, which thrive under the shade and drip of trees, for margins of water, rocks, edges walking, — bedded with slightly odoriferous, ornamental by their fruit as well as flowers, for botanica! or economical purposes, for shrubberies of limited extent, 6542 to 6505.

Shugborough House, Staffordshire, 7580.

Sibaldia, pentan. pentag. and rosacea, H. peren.

Eur. Alpines which grow in loam and peat, and may be increased by cuttings, under a hand-glass.

Sibthoria, diyn. angios. and scrophularineae, a H.
Sluices, their form and situation, 1951.
Sluice, to force, 3462.
Smithias, diadel. decan. and leguminosea, a S. an. E. Ind. of easy culture.
Smut, — see Ustilago.
Smyrnium, alexanders, pentan. dig. and umbelliferose, H. peren. and a. Eur. and N. Amer. of easy culture.
Smyrnium olusatrum, the garden alexanders or alexanders, 2988.
Snail, — see Helix.
Snake's beard, ophiopogon japonicus.
Snake's tongue, lycodium sandersoni.
Snakewood, groecia peltata.
Snap-dragon, antirrhinum majus.
Snap-tree, justicia hyssopifolia.
Snow, its collection, 1254; heat from, &c. 1207.
Snow, F., his works on gardening, page 1102. A.D. 1713.
Snowberry, chionocca racemosa.
Snow-dog, alnus galli nalis.
Snow-flake, — see Leucocda.
Soap-berry, — see Sapium.
Soberini, S., his works on gardening, page 1198. A.D. 1622.
Soft-grass, — see Hoica.
Softwooded timber-trees, 7125.
Soil, 257; mixed soils, 928; aquatic soils, 929; earthy soils, 930; vegetable soils, 938.
Soils, as indicated by spontaneous vegetables growing on them, 1063; list of plants indicating the moistness of our soils.
Soils, improvement of, 1068; by pulverisation, aeration, alteration, removal of superabundant ingredients, incineration, changing the condition of the soil, cetera, drainage, subterraneous irrigation, surface irrigation, changing the condition of the land in regard to atmospheric influence, solar influence and shelter, rotation of crops. Sir H. Davy's opinion on rotations, Grisenthwaite's opinion, 1069, to 1110.
Soils, table of, their nomenclature and classification, 1054; discovering their qualities, 1058; uses of soil to vegetables, 1053.
Solandra, pentan. monog. and solanaceae, S. tr. Jamaica, tree-growing plants, which, when it is increased they should flower, must be put in a state of rest by withholding water till their leaves drop. Cuttings root easily.
Solanderia, nightshade, pentan. monog. and solanaceae, S. and G. tr peren. and an. and H. peren. and an. of all easy culture in light rich soil.
Solanus leucopsicum, the love-apple, 4259.
Solanium melongena, aubergine-plant, 4236.
Solanum tuberosum, the potato, 3644; to force the potato, 3581.
Somerseshire, gardens and residences of, 7599.
Somoles, brook-weed, pentan. monog. and primulas, a G. peren. N. S. W. and H. peren. Brit. The first grows in loam and peat, and cuttings rooted under a glass-house; in the latter prefers a moist situation, and is increased by dividing at the root.
Sonchus oleraceus, the common sow-thistle, 4298.
Sorbi, F., his works on gardening, page 1121. A.D. 1804.
Sophisticov, — see Rumex.
Sourdour, monog. and leguminosea, a S. tr. India, H. tr. Japan, and H. peren. Eur. the tender species thrive well in light loam, and cuttings rooted under a glass-house; the hardy herbs require a rich loam, and are increased by seeds or dividing at the root.
Sorghum, polyg. monoc. and gramineae, a S. bien. and H. peren. and an. As. A.S. and Eur. of easy culture.
Soroecephalus, tetran. monog. and proteacea, G. tr. C. B. S. which require to be treated as protea.
Sorrel, — see Rumex.
South, of the use of peat, 8107. The use of peat, 7125.
Sparthe, sp. or spitter (spa pra, Lat. and Sax. spade, Dan.), an implement for penetrating and breaking up the earth, kinds of, 1530.
Spathelie, pentan. dig. and umbelliferose, a S. bien.
Caracass, of easy culture.
Spanish elm, cordia geraschenhuis.
Spanish nut, morsa sisyrinchium.
Sparaxis, trandr. monogyn. and iridee, G. peren. C. B. S bulbs which require the same treatment as lili.
Sparidi, Paulo, his work on gardening, page 1128. A.D. 1804.
Sparagnum, but-reed, monoc. trian. and arvodee, H. peren. Brit. marsh plants, of easy culture.
Sparmannia, polyan. monog. and tilaceae, a G. tr. C. B. S. which grows in loam and peat, and cuttings rooted under a glass-house.
Sparrow-wort, — see Passerina.
Spathe, tanan. monog. and proteacea, G. tr. C. B. S. which require the same treatment as protea.
Spathelie, pentan. dig. and umbelliferose, G. and H. tr. Europe and Africa, which thrive in loam and peat, and are readily increased by seeds, or by young cuttings in sand under a bell-glass.
Specyella, tetran. monog. and proteacea, G. tr. C. B. S. which require the same treatment as protea.
Spathelie, pentan. dig. and umbelliferose, G. and H. tr. Europe and Africa, which thrive in loam and peat, and are readily increased by seeds, or by young cuttings in sand under a bell-glass.
Species, William, his works on gardening, page 1108. A.D. 1775.
Species, — see Veronica.
Spergula, spurrey, decan. pentan. and Caryophylleae, H. peren. and an of easy culture in soft moist soil.
Spermacoce, button-weed, tetran. monog. and ru-biaceae, a S. tr. peren. and bien. As. and Afr. which grow freely in loam and peat, and are increased by cuttings under a glass-house, or by seeds.
Spharanthus, syngen. polyg. segreg. and cyanaraceae, a S. peren. E. Ind. and G. an. C. B. S. of easy cultivation.
Sphorolobium, decan. monog. and leguminosea, C. tr. H. Noll. pretty plants, which grow in sandy loam and peat, and young cuttings root readily in sand under a bell-glass.
Sphenogyne, syngen. polyg. frutian. and corymbiferæ, G. tr. and a H. an. C. B. S. which thrive well in light rich soil, and cuttings, in the shade, under a hand-glass, root freely.
Sphinx elpenor, the elephant hawk-moth, 6193.
Spiderwort, see Tradescantia.
Spilanthus, sp. dian., dianthus, and verbeneae, a Gr. tr. C. B. S. which may be treated as sphenogyne.
Spigelia, worm-grass, plant, monog. and gentianæ, a Gr. tr. W. & S. Amer. which are best grown in loam and peat, and are readily increased by cuttings.
Spikemill—see Althamanta.
Spikemulch—see Elecotrichia.
Spikenard, valeriana satamansi. V. celtica and officinalis may be used as substitutes by those who prefer this sort of herbarium.
Splanthes, syngen. polyg. equal. and corymbiferæ, a S. peren. bien. and an. E. Ind. and S. Amer. which grow in rich light soil, and are readily increased either by cuttings or by seed.
Spinaceous Spilanthes, 3766.
Spinacia oleracea, the common spinage, 5167.
Spinage, spinacia oleracea, 5766.
Spindle-tree, see Euonymus.
Spirea, icos. di-pentag. and rosaceæ, H. tr. and peren. Eur. and N. Amer. all of easy culture.
Spissæa, 4530.
Spitz, A. C., his work on gardening, page 1126. A. D. 1798.
Spiewnwort—see Asplenium.
Spofforth, a residence near Wetherby, Yorkshire, 7582.
Spondias, hogo-plum. decan. pentag. and terebintheæ, S. tr. W. Ind. which grow freely in loam and, and large cuttings root in sand under a hand-glass.
Sponge-tree, mimoso farnesiana.
Spongia triv. dig. and gramineæ, a H. an. India, of the easiest culture.
Spratshorshall, Yorkshire, 7582.
Sprungel, Kurt, his Gazette of Gardening, page 1954. 1815.
Sprengel, pentan. monog. and epericæae, a G. tr. N. S. W. which thrive in sandy peat, with the plant well drained, and kept rather in a shady aspect; young cuttings root in sand under a bell-glass.
Spring Garden, a seat in Galway, 7572.
Spring-grass, see Anthoxanthum.
Spring Grove, Middlesex, 7520.
Spurge, see Euphorbia.
Spurrey, see Spergula.
Squill, see Scilla.
Stavilia, pentan. monog. and rhamnæae, G. tr. C. B. S. which thrive in sandy peat, and young cuttings root in sand under a bell-glass.
Stable-dung, 1791.
Stachytopheta, bastard vervain, dian. monog. and verbenaceæ, S. tr. bien. and a G. B. W. Ind. and S. Amer. pretty plants, which thrive in rich light soil, and cuttings root readily under a hand-glass in heat.
Stackpool Court, a seat in Pembroke shire, 7503.
Stackpool Court, see Tradescantia.
Stackpool, syngen. equal. and corymbiferæ, G. tr. and a H. tr. Eur. which grow in rich light soil, and cuttings root freely under a hand-glass.
Staff-coo, see Celastrus.
Staffordshire, gardens and residences of, 7570.
Stamford Court, Worcestershire, 7566.
Stannmore House, Middlesex, 7521.
Stamit House, Sussex, 3751.
Stanton Harold, Leicestershire, 7573.
Stapelia, pentan. dig. and asclepiadæae, D. S. tr. C. B. S. succulents which grow in sandy loam and often thrive well with bright light, with little water. In light rich soil they grow more luxuriantly, but are very apt to dry off if they happen to get too much water; they are readily increased by cuttings and some by suckers.
Staphylea, bladder-nut, pentan. trig. and rhamnæae, H. tr. which grow in any soil, and are readily increased by seeds or layers.
Staudhardt, centaurea calcitrapa.
Stark,—see Aster.
Starka, syngen. polyg. super. and corymbiferæ, a F. peren. Chin. which thrives in rich light soil, and cuttings root readily under a hand-glass.
Statice, sea-lavender, pentan. pentag. and plum-bean, 6195. G. tr. and peren. C. B. S. and S. Eur. F. and H. petun. and Ind. Eur. The tender kind grows in sandy loam and peat, the others in light soil, and are all increased by dividing the root, the shoots, or cuttings.
Statistics of British gardening, page 7375; different conditions of men engaged in the practice and pursuit of gardening, 7571; operators or serving gardeners, 7374; gardeners, 7383; gardeners, 7383; gardeners, 4770. gardeners, 7380; gardeners, 7380; gardeners, 7374; private gardeners, 7415; commercial gardens, 7432; public gardens, 7490; leading gardens of the different counties particularised, 7410.
Staunton, Northamptshire, 7590.
Stauracanthus, diadel. decan. and leguminoseæ, a F. tr. and Peru, which grows in loam and peat, and is increased by cuttings or by seed with cuttings or young cuttings in sand under a bell-glass.
Steele, Richard, his work on gardening, page 1110. A. D. 1690.
Stellis, gynan. monan. and orichæae, S. peren. W. Ind. a parasite which may be treated as aroids, and increased by dividing at the root.
Stephanus, C. B. S. dig. and thymeleæae, a H. tr. S. Eur. which grows in light soil, and may be increased by cuttings under a hand-glass or by layers.
Stephanus, tradescantia. antiscus. and amyroporinae, a G. tr. N. Hol, which thrives in light, rich soil, and cuttings root freely under a hand-glass in heat.
Stephanus, pentan. monog. and epericæae, a G. tr. N. S. W. a beautiful plant which grows in loam and peat well drained, and young cuttings root in sand under a bell-glass.
Stephanus, Tradescantia. antiscus. and amyroporinae, a G. tr. N. Hol, which grows in loam and peat, and cuttings root freely in sand under a bell-glass.
Stephanus, monan. and stenarieææ, S. tr. and a G. tr. E. and W. Ind. which thrive in loam and peat, and ripened cuttings, not deprived of their leaves, root readily in sand under a hand-glass in heat.
Steenber, Baron von, his works on gardening, page 1127. A. D. 1811.
Stevens, syngen. polyg. aquat. and corymbiferæ, a F. peren. H. peren. and an. Mexico, which answer best in loam and peat, in pots, and cuttings root readily under a hand-glass.
Stelis, Mary, his writings on gardening, page 1105. A. D. 1739.
Stellina, monan. and ephorbiææ, a G. tr. W. Ind. and H. tr. China and N. Amer. which grow in loam and peat and cuttings root readily under a hand-glass; the tender kinds in sand.
Stinking horehound,—see Ballota.
Stipa, feather-grass, trig. dig. and gramineæ, a H. an. S. Amer. and H. peren. Eur. of easy culture.
Stirlingshire, gardens of, 7631.
Stirring the soil, use of, 2591; and see Soils, their improvement.
Stisser, J. A., his works on gardening, page 1123 A. D. 1731.
Stitchwort,—see Stellaria.
Stizolobium, cow-tick, dianel. decand. and leguminoseæ, a F. tr. W. Ind. which thrive well in light, rich soil, and young cuttings root in sand under a bell-glass.
Stobææ, syngen. polyg. aquat. and corymbiferæ, a G. tr. C. B. S. which may be treated as stizolobium.
Stock, — see Mathiola.

Stocks, for grafting, science of, 2020, to 2024.

Stokes, Henry, a gegirog. and corymbiferous, G. tr. C. B. S. which may be treated as stizolium.

Stoke, a seat in Herefordshire, 7508.

Stoke, or the excavation in one side of which hot-house furnaces are often built, and the hole contains fuel for its supply.

Stoke-paupers, 7563.

Stoke Park, Buckinghamshire, 7547.

Stoke Park, Wiltshire, 7597.

Stokefield, Yorkshire, 7385.

Stokesia, syn. polyg., aquar. and cyanopopheco, a G. peran. Carolinii, a pretty plant which grows in rich, light soil, and roots freely under a hand-glass.

Stokestown, a seat in the county of Roscommon, 7671.

Stole (from stola, Lat. a shoot or twig), trees which, when cut over by the surface, shoot up again.

Stone-crop, — see Sedum.

Stone-fruit, catalogue, of 4480.

Stoneham Park, Hampshire, 7543.

Stones, how to operate with in gardening-scenery, 7290.

Storax, — see Styrax.

Storck, — see Pelargonium.

Stornberg, his plan of a Chinese garden, 478.

Sourhead, a seat in Wiltshire, 7597.

South Hall, Glamorganshire, 7508.

South Hill, Gloucestershire, 7525.

Stove, dry, — see Dry-stove.

Stove, moist, or bark-stove, — see Bark-stove.

Stove-plants, — see Dry-stove.

Stove, a seat in Buckinghamshire, 7548.

Stovels, a seat in Gloucestershire, 7565.

Strowdale Hall, in Queen's County, 7559.

Strudmore Vale, a seat in Cardiganshire, 7607.

Stranumon, datura stramonium.

Strapwort, corriogilla littoralis.

Stratiotes, water-solium, are dodec., and hydrocharis, a H. peren. Eng. an aquatic which only requires to be thrown into a pond or aquarum.

Stratfield Park, Hampshire, 7504.

Straw coverings used in gardening, 1508.

Strawberry, — see Fragaris.

Strawberry-bisile, — see Bictum.

Strawberry Hill, Middlesex, 7520.

Strawberry-tree, — see Arbatus.

Streams of water, how to improve in gardening-scenery, 7283.

Streatham, Surrey, 7597.

Street-gardens, 7592; their management, 7426.

Strebitzia, pentand. monogyn., and musaceus, G. tr. C. B. S. which grow in sandy loam, and are increased slowly by suckers. Rubbing the pollen on the stigmas, when the plants are in bloom, propagates them. (From Syngenia).

Streptopus, hexan., monogyn. and amphilac., H. peren. Eng. an aquatic which only requires to be thrown into a pond or aquarium.

Suckers, partly moveable, 1530; earth-pit, backpit, fluit, pit, M'Phail's pit, Alderstone pit; pit with rising frame, West's pit, &c., 1540. to 1544.

Stuctures, fixed, 1550; garden walls, brick, stone, or mortared with lime, or三位, (in sandy loam, or on or near black Moor, which will thrive and flower freely in light sandy loam, and are increased by layers or seeds.

Subularia, awtwort, tetral. silic., and crucifereus, a H. an. Eng. a shrub which thrives and flowers freely in light sandy loam, and are increased by layers or seeds.

Suburban villa, 7585; suburban house, 7596; their management, 7430.

Succelis, a plant (from succela, Lat. to cut down, and repululto, Lat. to bud or shoot), trees which stol, or which being cut over spring again.

Succory, — see Cicorium.

Succory, tarax., silic., and crucifereus, a H. ap. Min. peren. of common culture.

Suckers to propagate by, 1592.

Suckers, to propagate by, 1592.

Suckers, to propagate by, 1592.

Suffocation, a disease of plants, 803.

Suffolk, gardens and residences of, 7552.

Sutton Court, Herefordshire, 7568.

Sugar maple, — see Syngenia.

Suir Castle, a seat in Tipperary, 7567.

Sulphur-wort, — see Puccedanum.

Sultan's garden at Constantinople, 306.

Suckers, to propagate by, 1592.

Summer Hill, a seat in Kent, 7538.

Sun-dew, — see Drosera.

Sun-dials, as garnet-decorations, 1834.

Sun-fern, polypodium phegopteris.

Sunflower, — see Helianthus.

Sun-rose, — see Helianthemum.

Sun-suckers, — see Punctulas.

Sundown, — see Tippeary.

Sun-rose, — see Pelargonium.

Sundown, — see Tippeary.

Sunnny, — see Tippeary.

Summer Hill, a seat in Kent, 7538.

Sun-dew, — see Drosera.

Sun-dials, as garnet-decorations, 1834.

Sun-fern, polypodium phegopteris.

Sunflower, — see Helianthus.

Sun-rose, — see Helianthemum.

Sun-suckers, — see Punctulas.

Sundown, — see Tippeary.

Sunnny, — see Tippeary.

Sun-rose, — see Pelargonium.

Sundown, — see Tippeary.

Sunnny, — see Tippeary.

Sundown, — see Tippeary.

Sunnny, — see Tippeary.
Syndrella, *syngenesia polymagia* superfusa and *corymbifereae*, a S. an. W. Ind. of common culture, 1749.

Persea and China, of easy culture.

Syrenia, common, — see Philadelphia.

Syringa, garden, different sorts of, 1148.

T.

Tabern. ic., *Icones plantarum* (eadem ac in tabernaeontiani Kraruterbuch).

Tabernamenta, pentan. dig. and apocyncea, S. tr. wifi. 1802. Ind. which thrive well in loam and peat, and cuttings root in sand under a glass.

Taecu, *hexan. monog.* and *aroideae*, S. peren. E. tree which grow in loam and peat with little water, and are increased by suckers.

Tacamahac, *populus balsamifera*.

Tages, syngenesiobly *corymbifereae*, a S. peren. and H. an. S. Amer. of common culture.

Taille d'ete, summer pruning, 2138.

Talih, *Talih* varieties of easy culture.

Taliar, a seat in Caernarvonshire, 7614.

Talium, *dodoc. monog.* and *portulaceae*, S. tr. and bien. W. Ind. and S. Amer. of a succulent nature, which grow in light sandy loam, and cuttings root freely.

Tallics, or numbering instruments, different kinds of, 1376.

Tallow-tree, *stillingia sebifera*.

Tamarindus, — see Tamarindus.

Tamarindus, *tamarind-tree*, monadelph. trin. and *lignum*; a S. tr. W. Ind. which grows in loam and peat, and cuttings root under a bell-glass in sand.

Tamarix, — see Tamarix.

Tamarix, *tamarisk*, pentan. trig. and *portulaceae*, a S. tr. E. Ind. and H. tr. Eur. of easy culture, and increased by cuttings.

Tamarix, *black-brier*, *brioc. hexan.* and *smilacceae*, a G. tr. C. B. S. and H. peren. Eur. The G. species T. elaeophila, or elephant's foot, is a curious plant which thrives in light, rich soil, and which, when the plant is in a dormant state, should be increased 'by young cuttings to be taken off at a joint, and planted in pots of sand in bottom heat under a hand-glass.' (Bot. Cultiv. 292.)

Tamarix, sorts of easy culture.

Tamus communis, the common black briony, 4282.

Tang, — see Bark for the use of tanners.

Tannery, *Tannery Hall*, a seat in Merionethshire, 7612.

Tanacetum vulgare, and *common tansy*, 4187.

Tansy, — see Tanacetum.

Tare, — see Ervum.

Tatia, A., his works on gardening, page 1120. A. D. 1791.

Tatton Park, Cheshire, 7391.

Taurida, gardens of, 529.

Tavistock, a seat in Devonshire, 7600.

Taymouth, a seat in Perthshire, 7656.

Tea-tree, *camellia bohea* and *C. viridis*.

Teak-wood, — see Teckons.

Tassel, — see Dipeearum.

Tea, *Thea sinensis*, teaz, *pentan.* monog. and *verbaneacea*, a S. tr. E. Ind. which grows in loam and peat; ripened cuttings root freely in sand under a glass.

Telephium, *orpine, plantan. trigyn.* and *portulaceae*, a H. peren. S. Eur. well adapted for rockwork, and easily propagated.

Telopea, *wartah*, *teten.* monog. and *proteaceae*, a G. tr. N. S. W. one of the most beautiful of green-house plants, which grows in equal parts of loam, peat, and sand, well drained, not over-watered, and placed in an airy situation; ripened cuttings are set off at a joint, just before growth commences, root in sand under a hand-glass, but not plunged in heat.

Temple, Sir William, his works on gardening, page 1101. A. D. 1685.

Temple Grove, formerly Sheen Grove, near East Sheen, Surrey, the seat of Sir William Temple's, and operations referred to by Evelyn and himself. The house is now a boarding-school, 1656.

Templemore, a seat in Tipperary, 7607.

Templtonia, diadel. decan. and *leguminosseae*, a G. tr. N. Holl. which grows in sandy loam and peat, and young cuttings root freely under a bell-glass in sand.

Temporary country-residence, 7281.

Tenthredinidae, a natural order of insects, comprehended chiefly the Linnaean genus tenthredos, or saw-fly.

Tephrosia, diadel. *decane.* and *leguminosseae*, S. and G. tr. peren. and bien. C. B. S. Ind. and Amer. which thrive in loam and peat, and are increased by cuttings in sand under a bell-glass.

Terebinthinantes, trees such as have a resinous, or turpentine odor.

Terebenthine of grafting, 2008.

Tereodinum pinus, the nocta pinastri, L. a moth whose caterpillar feeds on the leading shoot of the cone of pine, and often leaves that tree without a leader, 7044, and 900.

Terminalia, *polyg. monoece.* and *combretaceae*, S. tr. E. Ind. which grow in sandy loam, and ripened cuttings, not defoliated, root in sand under a bell-glass.

Terraces, 7266.

Tesselaar, M., his works on gardening, page 1120. A. D. 1791.

Tetragonia, *icos. di-pentag.* and *ficioidea*, G. tr. peren. bien. and an. C. B. S. and Austral. somewhat difficult, which prefer sandy soil, and root readily by cuttings.

Tetraigonia expansa, New Zealand spinach, 7394.

Tetragonothece, *syngen.* polysy. super. and *corymbeifereae*, a G. peren. Virgin, which grows in light, rich soil, and is increased by dividing at the root, or by seed.

Tetraheca, *octan. monog.* and *tremadorecum*, a G. tr. N. S. W. a pretty plant, which thrive in loam and peat, and cuttings root in sand under a bell-glass.

Tetraydy Park, Cornwall, 7591.

Thalassia vulgaris, and *common seagrass*, a G. peren. S. Carolin. an aquatic, rather hardy, and increased by dividing at the root.

Thamnos, *modow-run*, *polyg.* and *ranunculaceae*, H. peren. Eur. and N. Amer. some of which are adapted for rockwork, or growing in pots, and all are of easy culture.

Thames Park, Oxfordshire, 7588.

Thelymitra, *gyand.* monan. and *orchideae*, G. peren. N. S. W. which grows in sandy loam and peat, requires little water, not in a growing state.

Theobald, a seat in Hertfordshire, 7544.

Theobroma, *chocolate-nut*, *polysy.* decan. and *maccabeateae*, S. Amer. which grows in light, rich soil, and cuttings root in sand under a hand-glass.

Theometer, different sorts of, for gardens, 1488, 1489, and 1490.

Thermopsis, decan. monog. and *leguminosseae*, H. peren. Siberia, a pretty plant, rather difficult of cultivation; this species grows best in light loam, and is increased by seed.

Thesium, *broad-leaved*, *pentan.* monog. and *smilacceae*, S. tr. H. peren. Eur. Amer. and C. B. S. of which the H. species grow best in chalky soil, and are increased by seeds, and the G. tr. is of common culture in light loam.

Thermopsis, his works on gardening, page 1126. A. D. 1805.
Thier-garten (wild beast garden), a public park at Berlin, 206.

Thierrot, —, his works on gardening, page 1118. A. D. 1760.

Thistle, — see Carduus.

Thaisp, shepherd's purse, tetrad. silic. and cruciferae, H. peren. bien. and an. of easy culture.

Thibaud, — his work on gardening, page 1105. A. D. 1757.

Thoresby Park, Nottinghamshire, 7576.

Thorn, — see Dool.

Thornbury Castle, in Gloucestershire, 399.

Thorndon Hall, Essex, 7542.

Throgmire, a seat in Worcestershire, 7566.

Thurber, his works on gardening, page 1192. A. D. 1819.

Thouin, André le Chevalier de, his works on gardening, page 1147. A. D. 1757.

Thouin, Mons. Gabriel, his works on gardening, page 1192. A. D. 1819.

Thouin, Mons. Jean, his works on gardening, page 1192. A. D. 1816.

Throckley Hall, Yorkshire, 7592.

Thrift, — see Statice.

Thrisan, hexan. monog. and palmacee, a S. tr. E. Ind. which thrives in sandy loam, and is increased by (imported) seeds.

Thrinica, syngen. polyg. aequal. and cichoracee, a H. peren. and an. of Afr. and Africa, of common culture.

Thrips, a genus of hemipterous insects, 2244.

Threatowt, — see Trachelium.

Thuya, arbor vitae, a coniferous, monoec. and coniferae, a G. and F. tr. H. tr. As. Af. and Amer. The tender kinds grow in loam and peat, and are increased by cuttings under a bell-glass in sand; the hardy species grow in any soil, and are increased by seeds.

Thumb-pot, a garden-pot of the least size.

Thunberg, Sir Charles Peter, M. D. his works on gardening, page 1190. A. D. 1799.

Thunbergia, — see Turritis.

Townsley, W., 1766.

Towcester, — see Turrifia.

Tower-mustard, monog. and campanulae, a G. tr. and H. bien. France and Brit. of common culture.

Tradescant, John, his writings on gardening, page 1192. A. D. 1652.

Tradescantia, spider-wort, hexan. monog. and conmelinee, a S. tr. H. peren. and an. E. and W. Ind. and A. and S. Amer. all of easy culture in light, rich soil.

Tradesman-gardener, 7388.

Tradesmen's villas, 7393; their management, 7424.

Tragia, monog. tetran. and euphorbiacee, a S. tr. peren. and an. and a H. an. W. and E. Ind. which grow in light soil, and cuttings root freely.

Tragopogon, goat's beard, syngen. polyg. aequal. and cichoracee, H. bien. of easy culture.

Tragopogon porrifolius, the sal afy, 3750.

Training trees and plants, different methods of, 3140.

Transplanter, for herbaceous plants, 1390.

Transplanting, different methods of performing, 2073.

Trapa, water-caltrops, tetran. monog. and hydrocharidee, a G. peren. and H. an. aquatics of easy culture, 6057.

Trapa natans and bicornia, 6037.

Trapa, forvermin, different sorts of, used in gardening, 1435 and 1473.

Trasternaugh, a seat in Westmeath, 7682.

Trainelling person, 7385.

Trecade-mustard, clypeola iouthallsi.

Tredegar Park, Monmouthshire, 7567.

Treclean-dainie, bocconia frutescens.

Trecalar, H. a ser. aeroba.

Trecat-surveyor, 7401.

Trecat-planter, 1468.

Trees, that grow individually, 6744; in civil architecture, military architecture, naval architecture, construction of machines, implements, utensils, fuel, tanning, dyeing, various uses, food, medicine, poison, 6745 to 6790.

Trees, classification of, according to their uses, 6768; for timber, bark, charcoal, ashes, pales and fencing, hoops, &c. shelter, shade, improving bad soil, and for staking and fencing, 6780 to 6790.

Trees, their uses in ornamental scenery, 6790; magnificence, extent and design, growth, duration, and expression, 6790 to 6830.

Trees, their wounds, bruises, casualties, and defects, 6832.

Trees, insects and vermin by which they are infested, 6934.

Trees, their products, 6935; prunings, thinnings,
seeds, osier-grounds, coppice-woods, 6933, to 6940.
Trees, season for cutting, 6941; mode of cutting, treading, poling, and falling, operation of felling, measurement of falling, 6942 to 6957.
Trees, uses of their roots, 6951; method of charming, 6952.
Trees, valuation of, 6953; as plantations, as timber, measurement of, 6957 to 6972.
Trees, nursery for, see Nursery.
Trees, their nursery culture, 6954; coniferous, nut-bearing, berries and capsule-bearing trees, with small seeds, with leguminous seeds, small soft-seeds, general culture of, 6953 to 6968.
Trefoil, see Tribolium.
Trelawney House, Cornwall, 7601.
Tremadoc, 1870.
Trent Place, Middlesex, 7321.
Trentham, a seat in Staffordshire, 7570.
Treviranis, didymum, angios and scrophulariaceae, a species of flowering freely in sandy loam and peat, the pots being kept dry as soon as the flowering season is over till the roots begin to wither.
Trew, dioecy. polyan and, see, a S. tr. E. Ind. which grows in loam and peat, and cuttings root in sand under a hand-glass.
Trianon, a rose garden near Paris, 172.
Triaenthes, decan, and portulacca, S. an. E. and W. Ind. of common culture.
Trioilus, culture, monog. and rutaceae, a S. peren. and an. and H. Amer. which grow in light soil, and cuttings root freely in sand under a hand-glass.
Triticum, decan, monog. and melaceae, S. tr. W. Ind. which thrive in loam and peat, and cuttings root in sand under a hand-glass in heat.
Trichodesma, pentagon. monog. and boragineae, a S. an. and H. e. Ind. and C. B. S. of common culture.
Tricholium, trian. dig. and gramineae, H. peren. N. Amer. of easy culture.
Trichomanes, cryptog. filices and filiceae, a H. peren. Brit. of easy culture in loam and peat in the shade.
Trichomena, trian. monog. and iridaceae, G. peren. and a H. peren. bulbs which may be treated as ixiia.
Trichorhum, trian. monog. and cyperaceae, H. peren. Brit. and N. Amer. grasses of easy culture in moist soil.
Trichosanthes, snake-gourd, monac. monad. and cucurbitaceae, a S. peren. and F. an. the S. species thrive best in rich sandy loam, and cuttings root freely under a hand-glass in a moist heat; the others may be treated as cucumis.
Trichosperma, dichog. monog. and labiateae, a H. bien. and an. N. Amer. of common culture.
Tridentalis, winter green, heptan. monog. and primulaceae, a H. peren. which grow best in light soil, and are increased by dividing the root at the root or by seeds.
Triedula, Martin, his writings on gardening, page 1103. A.D. 1794, and page 1130. A.D. 1740.
Tribolium, trefoil, diadelph. decan. and leguminoseae, H. peren. bien. and an. Eur. Afr. and N. Amer. of easy culture, and increased by dividing the roots or by seeds.
Triglochin, arrowgrass, hexan. trig. and alismaceae, a G. peren. and H. peren. C. B. S. and Brit. marsh plants of easy culture.
Trigonomella, ferns, diadelph. and leguminoseae, S. an. and H. peren. bien. and an. E. Ind. and Eur. of easy culture.
Trillium, hexandria trigynia and smilacaceae, a G. peren. and H. peren. N. Amer. which do best in a best of peat in a moist shady situation, and are increased, though slowly, by dividing at the root.
Tring Park, Hertfordshire, 7544.
Tridodium, trian. dig. and gramineae, a H. peren. Brit. of easy culture.
Trigo, forwort, pentan. monog. and caprifolce, H. peren. N. Amer. which grow freely in rich, light soil, and are increased by cuttings under a hand-glass, or by dividing the root.
Trigonella, monog, trian. and gramineae, a H. peren. N. Amer. of easy culture.
Trisetum, trian. dig and gramineae, a H. peren. and an. Eur. of common culture.
Tristaria, polyac. icos. and myrtaceae, G. tr. N. S. Amer. which grow in sandy loam and peat, and cuttings root in much ripened, root readily in sand under hand or bell glasses.
Triticum, wheat-grass, trian. dig. and gramineae, H. peren. and an. Eur. and Asia, of common culture.
Tritonia, hexan. monog. and hemerocallideae, a H. peren. C. B. S. which thrive best in peat soil, and cuttings root by division at the root.
Trionys, trian. monog. and iridaceae, Br. G. peren. C. B. S. bulbs which may be treated as ixiia.
Trochis, dodoc. monog. and tiliacceae, S. tr. and an. E. and W. Ind. which grow in loam and peat, and cuttings root in sand under a hand-glass.
Trolles, globe-flower, polyan. polyan. and ranunculaceae, Eur. and N. Amer. of easy treatment.
Tropaeolum, Indian cress, octan. monog. and gera-niaceae, G. tr. bien. and an. Peru, which grow in light rich soil, and are of easy increase by cuttings or seeds.
Tropaeolum majus, common Indian cress, 4116.
Trophis, ramn-tom-tiee, trian. tetran. and, see, T. tr. E. and W. Ind. which grow freely in loam and peat, and cuttings root under a hand-glass in sand.
Trophym, Samuel, his work on gardening, page 1104 A. D. 1739.
Trowel, the garden, 1308.
Trowell, Jabez, polyan. equol. and cichoraceae, H. peren. N. Amer. which grow freely in rich, light soil, and are increased by seeds.
Troy House, Monmouthshire, 7561.
Tulip, see Bichrest, his work on gardening, page 1120. A.D. 1780.
Trumpet-flower, see Bignonia.
Turf, turf-killer, Brit. turf-killer, turf-raser, Turf, 7601.
Tuncheon (tuncheon, fr. tunecess, Lat.), a pole or rod cut to the length of a staff or longer, sometimes adopted in making willow plantations.
Tuschandi, 1. B. L. Baron de, his work on gardening, page 1118. A. D. 1768.
Tuber cibarium, the truffle, 4349.
Tubercle, Brit. turf-killer, turf-raser — see Polyanthes.
Tuilleries (tile-grounds, or tile-killen), gardens of the, at Paris, 161.
Tulbagia, hexan. monog. and hemerocallideae, H. peren. C. B. S. which grow in sandy loam, and are increased by offsets from the bulbs.
Tulip, see Tulips.
Tulips, see Lilium, to Lisiridencorn.
Tulipa, his, hexan. monog. and liliaceae, H. peren. bulbs, Eur. which grow best in sandy soil, and are increased by offsets.
Tulipa gesneriana, the common tulip, 6942.
Tupelo, see Nyssa.
Tupistra, hexan. monog. and arideae, a peren. Amblyca, which may be grown in loam and peat.
Turf, the superiority of British, 5399.
Turf-raser, A.E., 1517 to 1519.
Turf, the transplanting or laying down turf, 2101.
Turmeric, see Curcunna.
Turner, his, see Brassica.
Turna, pentan. trig. and portulacca, S. tr. an. and H. an. which grow in rich, light soil, and are increased by cuttings under a hand-glass or by seeds.
Turnsole, see Heliotropium.
Turritis, tower-mustard, tetrad. silig. and cruciferaceae, S. tr. and an. Eur. of easy culture.
Tussilage, colts-foot, syngen. polyan. super, and corymbifereae, a S. bien. and H. peren. W. Ind. and Eur. of easy culture. T. fragrans is a desirable plant for a green-house during winter, on account of the odor its flowers diffuse at that season.
Twin blade, listera ovata.
Tweedale, county of, as to gardening, 7623.
Twickenham, village of, in Middlesex, 7520.
Twickenham Park, Middlesex, 7520.
Twickenham Hall, Essex, 7641.
Tyford House, Middlesex, 7520.
Tynningham, a seat in Haddingtonshire, 7619.
Tzia, see Zaritizia, or Zaritiza, an imperial residence near Moscow, 502.
U.  

Udum salticum (udus, a, um, wet or moist, and salicinus, a willow-ground), a proper situation for growing willows.

Ulex, furze, diadel. decan. and leguminosce, H. tr. Brit. which grow best in dry soil, and are increased from seed.

Ulmus, elm-tree, pentan. dig. and amareace, H. tr. Brit. and N. Amer. and a G. tr. China, all of which thrive in loamy soil, and the G. species is increased from cuttings under a hand-glass. Ulmus campestris, and other species grown as timber-trees, 7081.

Uva lacte, 4326.

Umbo, the root — see Oxypaphus.

Underley Park, near Kirby Lonsdale, 6182.

Ungeheuer, J., A. his works on gardening, page 1123.

Uniola, sea-side oat, trian. dig. and gramineum, H. peren. N of easy culture.

Unions, polyan. poly. and annonaceae, a S. tr. Java, which grows best in light loam, and ripened cuttings root in sand under a hand-glass.

Up Park, Sussex, 7531.

Utulal, the garden of 948.

Uruan, hexan. monog. and musaceae, a S. tr. E. Ind. which thrives in loamy soil with plenty of water, and a strong heat, and is increased by imported seed.

Urena, mond. polyan. and malvacaceae, S. tr. and a G. tr. E. Ind. and Suriham, which grow in loam and peat, and are increased by seeds or cuttings.

Urquetalum, hexan. monog. and asphodelaceae, G. and F. peren. C. B. S. bulbs which may be treated as annuals.

Urtica, nettle, monog. tetran. and urticaceae, S. tr. and peren. W. Ind. and F. and H. peren. and an. Eur. all of which grow well in rich, light soil, and are readily increased by the usual means.

Urtica dioica, the common stinging nettle as a pot-herb, and to force, 4586.

Utengia, a small fungus, which is thought to occasion the blight and smut, 787.

Utility, as expressive of design in landscape-garden, page 761.

Utricularia, hooded mifioft, diant. monog. and len-tilibræum, H. peren. Brit. marsh plants, which prefer peat soil, or they will grow in pots of sphagnum with a little peat earth at bottom, set in pans of water.

Uvaria, polyan. poly. and annonaceae, S. E. and W. Ind. which thrive best in sandy loam, and ripened cuttings root in sand under a hand-glass in heat.

Uvaria, hexan. monog. and malvacaceae, H. peren. and an. Brit. of easy culture.

Valemont, l'Abbé de, a French writer on gardening, page 1116. A. D. 1705.

Valentines, a seat in Essex, 7342.

Valerian, — see Valeriana.

Valeriana, valerian. trian. monog. and dipsece, H. peren. and an. Eut. of easy culture; the small variety grows best in light soil, and answer well for pots or rockwork.

Valeriana locusta, or lamb-lettuce, — see Fedia.

Valley of the Volleys, seated in Fifeshire, 7635.

Van Dieman's Land, gardening of, 504.

Van Kampen, et filis, their works on gardening, page 1129. A. D. 1706.

Van Schoten, Francis, his works on gardening, page 1129. A. D. 1682.

Vander Groen, J., his working on gardening, page 1125. A. D. 1700.

Vanes as decorations, 1835.

Vanguiera, pent. monog. and rubiaceae, a S. tr. Ind. which grows in sandy loam and peat, and cuttings may be increased in heat and under a hand-glass.

Vanilla, gynan. monan. and orchideæ, S. tr. trailers and parasites, which root at every joint into the bark of trees, and when they do, they may be treated as airriés, and are readily increased by cuttings.

Various British authors, who have touched incidentally on gardening, page 1105. A. D. 1700.

Vegetable kingdom, origin and progress of the study of, 547; among the ancients, in modern times, in the present day, 548, to 569.

Vegetable glossole, or the names of the parts of plants, 555.

Vegetable phytozography, or the nomenclature and description of plants, 577; vulgar names of medicinal plants, scientific rules for names, names of classes and orders, names of genera, of species, of varieties, of plants, descriptive names, descriptive names of seeds, herbariums, methods of study, &c. 558 to 582.

Vegetable taxonomy, or the classification of plants, 585; methods in use, table of the Linnean method, by the method of Jussieu, 586; the Linnean system, and arrangement of the genera under the different classes and orders, arrangement of the genera under the classes and orders of Jussieu, 584 to 589.

Vegetable organology, or the external structure of plants, 590. Perfect plants: their conservative organs, root, trunk, branches, leaves, flowers, fruit, seeds, reproductive appendages — organs, glands, tetrads, stipule, ramenta, armature, pubescence, anomallies, roots, seminal organs, organ of reproduction, organ of ornamentation, organ of destruction, organ of receptacle, infrutescence, fruit, reproductive appendages; appendages proper to the flower of the fruit. Imperfect plants: filices, equistina, and lycopodines — conservative organs, reproductive organs, musci — conservative organs, reproductive organs, hepaticæ — conservative organs, reproductive organs, alge and lichens—conservative organs, reproductive organs of the algae; fungi — conservative organs, reproductive organs, use of the fungi, 591 to 604.

Vegetable affections, or the internal structure of plants, 605. Decomposite organs — seed, nucleus, pericarp, flower-stalk, leaf-stalk, gems, buds, bulbs, propago, gongyline, cayadees, appendages; composite organs — stipule, petiole, pith, cortical layers, ligneous layers, concentric layers, divergent layers; elementary or vascular organs — utricles, tubes, large tubes, small tubes, apertures, pores, gaps, appendages, 606 to 634.

Vegetable chemistry, or primary principles of plants, 635. Mechanical processes; chemical processes; compound products — gum, sugar, starch, gluten, albumen, fibrina, extract of catechu, of senna, of quinquina, of saffron, coloring matter, tan- nin, nitric muriatic principle, malic nitric principle, oxalic acid, citric acid, malic acid, gallic acid, tannic acid, benzoic acid, prussic acid, fixed oils, volatile oils, wax, butter of cacao, of coco, of nutmeg, wax of croton, wax of myrrh, resin, rosin, mastich, bloom, gum-resins, balsams, camphor, caschouche, cork, woody fibre, charcoal, sap, proper juice, salis, alkalies, earths, silica, magnesia, metallic oxides; simple products, 636 to 714.

Vegetable physiology, or the functions of plants, 715. Analysis of the seed — chemical phenomena, chemcal phenomena; food of the vegetating plant — water, gasses, carbonic acid gas, oxygen, hydrog. acid, oxides, extrasts, salts, earths, manures; process of nutrition — imbibition, assimilation, ascent of the sap, causes of the sap's ascent elaboration of the sap, of carbonic acid, of oxygen, decomposition of water, descent of the proper juice, causes of descent: process of vegetable development; elementary organs — compo-
site organs, annuals and annual shoots, perennials and their annual layers, circulation of vegetable juices; decompose organs, the root, the stem, the branches, the bud, the leaf, the flower, and fruit: anomalies of in the vegetable development — the root, the stem, the branch, the bud, the leaves, the flower, the fruit, the habit, physical virtues, during the propagation of vegetable species of the moderns, impregnation of the seed, access of the pollen, theory of the animalculist hybrids; changes consequent upon impregnation, external characters, internal changes; presentation of the species; equivocal generation, seeds, gems, runners, slips, layers, suckers, grafting; causes leading to the propagation of vital activity and character of vegetable vitality — excitability, heat, frondescence, efflorescence, maturation of the fruit; calendrical flora; irritability of stimuli, instinct, definition of the plant, 716, to 563.

Vegetable pathology, or the diseases and casualties of the lives of plants, 858; wounds and bruises, insect, boring, injury, pruning, felling, buds destroyed, leaves destroyed, decortication; diseases — blight, smut, mildew, decay, leaf blight; civil causes affecting the plants; distribution; suffocation, contortion, consumption; natural decay, of the temporary organs, flower, fruit, of the permanent organs, 860, to 907.

Vegetables in the domain of the economic distribution of plants, 908. Geographical distribution; physical distribution — temperature, elevation, moisture, soil, mixed soils, aquatic soils, earthy soils, vegetable soil, light; civil causes affecting the plants; distribution; characteristic, or picturesque distribution, systematic distribution, systematic distribution, arrangement of the British flora, application of the native flora of Britain, artificial flora, native countries of the exotics of British gardens, periods of their introduction; characteristics of the plants cultivated in British gardens, their botanical and horticultural distribution, according to the Linnaean system, according to that of Jussieu, British flora appropriate at the nurseries, hardy plants, greenhouse and dry-stove plants, hot-house plants, annuals, native and exotic, artificial application of the British flora, fruit-trees and plants, herbaceous plants used for culinary purposes, florists' flowers, hardy barren trees and shrubs, herbaceous plants used in agriculture for food, and in the arts, miscellaneous application of hardy herbaceous plants, application of various ornamental exotics which require the protection of glass, new habits of plants, 908.

Vegetable culture as derived from the study of plants, 1004: to increase the number and retain the native qualities of plants; to increase the number and maintain the qualities of plants; increasing the magnitude; to increase the number, improve the quality, and increase the magnitude; to form new varieties; to preserve plants for future use, 1004 to 1013.

Vegetable sculptures, their formation, 1844.
Vegetables, to form new varieties of, 1013.
Vegetables, to preserve for future use, 1844.

Vegetables composing the Hortus Britannicus, arranged according to the Linnean system, 588; the Jussieusian system, 589; to the departments of herbaceous and woody plants, 586.
Vegetables which first attracted man's attention as food, 26.
Vegetation to accelerate or force, operations for, 27.
Vegetation to retard, operations for, 2177.
Velzeia, gentian. dig. and carophyllace, a H. an. species of common culture.
Veltheimia, hexan. monog. and hemerocallideae, G. peren. C. B. S. bulbs, which grow in light soil, and are readily increased by offsets; or the leaves pulled off to the bulbs, and will dispose bulbs at their base, as will many other scaly and coated bulbs.
Veneria, a royal residence at Turin, 77.
Vente, Jardin de la Malmaison, Par E. P. Venet.
Venus, com. scandix peloton.
Venus, com. pauli. aquitectu.
Vepratum, polygam. monog. and melanthaceae, H. peren. Eur. and N. Amer. which grow best in rich sandy soil, and are increased by dividing at the root, or by seeds, which shoots soon, as soon as ripe.

Verbascum, mullein, pentan. monog. and solaneae, G. peren. and bien. and H. peren. bien. and an. all of easy culture on light soil.
Verbena, vervain, didyn. angios. and verbenaceae, H. gr. and an. and N. Amer. which thrive in any common soil, and are increased by dividing at the root.
Vernonia, polygam. super. and corymbiferae, S. an. and a tr. E. Ind. and W. and G. peren. and H. peren. Amer. which grow in common soil, and are readily increased by cuttings, seeds, or division of the root.
Vermin, traps and snares used for, in gardening, 1435, and 1473.
Vesia, com. polig. equal. and corymbiferae, a S. an. and a tr. E. Ind., and H. peren. N. Amer. which grow well in rich loam, and make a fine show in autumn.
Vesica, speedwell, dian. monog. and scrophulariaceae, G. tr. and peren. N. Hol. and H. peren. and an. Eur. all of easy culture in any soil; the G. species are propagated by cuttings under a handglass, and all the rest by seeds, or dividing the root.
Veronica beccabunga, brooklime, 600.
Veronica spicata, British tea, 4317.
Vesperis, violets, flowers, 477.
Vescaria, tetrad. silic. and cruciferaceae, H. peren. and a bien. S. Eur. of common culture.
Vespa vulgaris, the common wasp, 4857.
Vexations to culture, 716.
Vexations, the cause of, 716.
Vexations, the cause of, 716.
Vexations, the cause of, 716.

Vitex, chaste tree, didym. angios. and verbenaeeae, S. and G. tr. E. Ind. which grow in loam and peat, and cuttings root freely in sand under a hand-glass.

Vitis, vine, panetan. monog. and vitaceae, a S. tr. Ind. and H. tr. N. Amer. of easy culture, and readily increased by cuttings or layers.

Vitis vinifera, the common grape-vine, 4700; culture in the open air in various ways, 4816; in the vineyard and other hot-houses, 2940.

Vitiuea, a genus of ferns and filicaceae, a S. peren. Amer. of easy culture in loam and peat, and increased by dividing the root or by seeds.

Warbeck, George, his work on gardening, page 1129. A. D. 1759.

Volkamer, Johann Christoph, his works on gardening, page 1123. A. D. 1700.

Volkameria, dioec. angios. and verbenaeeae, S. tr. W. Ind. which thrive well in loam and peat, and cuttings root freely under a hand-glass.

Von Brocke, H. C., his works on gardening, page 1124. 1800.

Von Steierorff, K. H., his work on gardening, page 1125. A.D. 1790.

Von Spenoeck, his works on gardening, page 1127. A. D. 1750.

Von Weiss, K., his work on gardening, page 1124. 1800.

Von Wilke, G. W. C., his works on gardening, page 1124. A.D. 1783.

Von Fries, J. C., his works on gardening, page 1123. A.D. 1647.

W., Wildenow's Species Plantarum.

Wachendorffia, dioec. angios. and verbenaeeae, G. peren. C. B. S. bulbs which grow in sandy loam and peat, with little or no water when in a greenhouse. Cuttings are increased by offsets.

Wade, Walter, M. D., his tract on gardening, page 1114. A.D. 1811.

Wakefield Lodee, Northamptonshire, 7580.

Waldschmidt, A. D. 1790, his works on gardening, page 1123. A.D. 1712.

Waldsteinia, iocos. di-pentag. and rosaceae, a H. peren. Hungary; very suitable for rockwork or peat gardens. It grows in loam and peat, and is increased by parting the roots.

Wales, gardens and residences, of, 7602.

Walters, G., Lodge, Devonshire, 7800.

Walks, their formation, 1856; in horticulture, 2490; in floriculture, 6105; in landscape-gardening, 7243.

Wall-cress, — see Arabis.

Wall-flower, — see Chinnanthus.

Wall-tree nails and other fastenings, 7214.

Walls trees, their planting and management, 2490.

Wallen, A. K., his works on gardening, page 1127. A.D. 1866.

Wallerius, J. G., his works on gardening, page 1130. A. D. 1760.

Walls in gardening, structures for defence, enclosure, shelter, and the culture of the more delicate fruit-trees, different kinds of, 1550.

Walter, —— his works on gardening, page 1127. A.D. 1591.

Walsingham House, Norfolk, 7554.

Watber, John, monad. pantan. and tiliaceeae, S. tr. and a bien. E. Ind. and S. Amer. which grow in light, rich soil, and cuttings root in sand under a hand-glass.

Walton, a seat in Radnorshire, 7610.

Wanampee-tree, cookea punctata.

Wanstead House, Essex, 7542.

Waratah, camellia, — see Camellia.

Waratah, telopea speciosissima.

Wardour Castle, Wilshire, 7597.

Wavara, gardens of, 7522.

Wart-cress, — see Coronopus.

Wart-wort, euphorbia helioscopia.

Warton House, Lancashire, 7592.

Warwick Castle, Warwickshire, 7572.

Warwickshire, gardens and residences of, 7571.

Water, 1213; its constituent parts, how obtained in hot-houses, 1601 and 1688; different modes of procuring and preserving it, the open air winter, 1713 and 1822; forming excavations for, 1719; operating on in landscape, 7216.

Water-caltrops, — see Trapa.

Water-chickweed, montana, 7546.

Water-cress, — see Nasturtium.

Water-dropwort, — see Oenanthe.

Water-hemlock, phellandrium aquaticum.

Water-lily, —— see Nymphaea and Nuphar.

Watermelon, — see Cucumis melo, 7584.

Water-parsnip, — see Sinum.

Water-plantain, — see Alium.

Water-soldier, stratiotes aloides.

Water-retort, callichthrix aquatica.

Water-violet, hottonia palustris.

Water-wort, elatine hydropiper.

Waterbourne Harrington, a seat in Dorsetshire, 7598.

Waterfalls, their kinds and construction, 1826 and 7226.

Waterford, county of, as to gardening, 7695.

Watering-engines, different kinds of, 1448.

Watering-pot, different kinds of, 1614.

Wattled hurdle (Sina), a hurdle spliced or wrought of small shoots, used to shade beds or rows of young plants, or new-sown seeds, in gardening.

Watton Woodhall, Hertfordshire, 7544.

Watsonia, monad. and irisceae, G. peren. C. B. S. which may be treated as ixia in the greenhouse, or like the common ranunculus in the open air.

Wax-tree, igustrum lucidum.

Wayfaring-tree, viburnum lanata.

Weald Hall, Essex, 7542.

Weber, pantan. monog. and rubiceaeae, S. tr. E. Ind. which thrive in loam and peat, and cuttings root in sand under a hand-glass.

Weeding, 1893; weeding pincers, 1392; weeding gloves, 5371.

Weeks, Edward, his work on gardening, page 1114. A. D. 1784.

Weiss, F. W., his works on gardening, page 1124. A.D. 1755.

Weissmantel, J. N., his works on gardening, page 1124. A.D. 1759.

Wellesley, J., Hertfordshire, 7576.

Wellfield House, a seat in Radnorshire, 7610.

Wells for water, 7173.

Wenimby Manor House, Middlesex, 7520.

Wenyns Castle, a seat in Fifeshire, 7635.

Wenyns House, or Gosford House, a seat in East Lothian, 7619.

Wenecke, Jean George, his works on gardening, page 1105. A. D. 1767.

Wenof, G. T. K., his works on gardening, page 1126. A. D. 1804.

Wendellion, hexam. polyg. and menispermacae, a H. tr. N. Amer. which grows in peat soil, and is increased by layers.

Wentworth Castle, Yorkshire, 7582.

Wentworth House, Yorkshire, 7582.

West Beechworth, Surrey, 7527.

West Grinstead Park, Sussex, 7531.

West Head, Heits during cultivation, 6010.

Westmeath, county of, as to gardening, 7692.

Westmoreland, gardens and residences of, 7592.

Wexton, Sir Richard, his work on gardening, page 1100. A. D. 1707.

Wexton, Richard, Esq., his works on gardening, page 1108. A.D. 1770.

Westringia, didyn. gymnos. and labiateae, G. tr. Aust. which thrive in sandy loam and peat, and young cuttings root freely under a bell-glass in sand.
Z.
Zaluzania, syngen. polyg. super. and corymbiferae, a F. peren. Mex. which grows in rich, light soil, and cuttings root readily under a hand-glass.
Zamia, dioec. polyan. and eyecere, S. and G. tr. C. B. S. W. Ind. and Austral. which grow in light sandy soil, and some species may be increased by suckers.
Zamosc, a seat in Poland, 283.
Zannichellia, pond-weed, monoeec. monandria and naideae, a H. an. an aquatic.
Zanthoxylum, yellow root, pentan. polyg. and ranunculaceae, a H. tr. which grows in common soil, and is increased by suckers.
Zanthoxylum, tooth-hach-tree, dicercia pentand. and terebinthaceae, a S. and G. tr. and a H. tr. The tender species grow in sandy loam, and cuttings will root in sand under a hand-glass; the hardy sorts in any soil, and cuttings of the roots will shoot into plants in bottom heat.
Zepana, didyn. angios. and verbenaceae, a S. and G. peren. W. Ind. and Amer. which grow in light, rich soil, and cuttings root freely under a hand-glass.
Zerzitina, or Tzaritzina, a palace and gardens near Moscow, 292.
Zarskoje-selo, or Tsarskoje-selo, an imperial residence near Petersburg, 257.
Zea, Indian corn, monoeec. *trian. and gramineae, a H. an. Amer. of easy culture, 4335.
Zedary, curcuma scurubet.
Zephyr and G. Romer, their works on gardening, page 1127. A. D. 1815.
Zieria, tetran. monog. and rutaceae, a G. tr. N.S.W. a pretty plant, which grows in sandy loam and peat, and young cuttings root in sand under a bell-glass.
Zingiber, ginger, monan. monog. and scitamineae, S. peren. which grow in light, rich soil, and are increased by dividing at the root.
Zinnia, syngen. polyg. super. and corymbiferae, H. an. S. and N. Amer. of common culture.
Zizania, monoeec. hexan. and gramineae, a H. an. N. Amer. an aquatic which only requires to be sown in shallow water or on the margin of a pond.
Ziziphora, dian. monog. and labiateae, ff. tr. peren. and an. Eur. which grow freely in rich, light soil, and are increased by seeds or cuttings.
Zizyphus, pentan. monogynia and rhamnacea, S. G. and H. tr. As. Af. and Eur. of which the tender kinds grow well in loam and peat, and cuttings root in sand under a hand-glass; the H. species are increased by seeds or ripened cuttings under a hand-glass.
Zizyphus lotus, the true lotus, and Z. jujuba, the jujube-tree, 6018.
Zizyges, syngen. polyg. frustr. and cynaraeaceae, a H. an. Levant, of the usual culture.
Zornia, diadel. decan. and leguminoseae, a S. tr. and an. E. Ind. which grow freely in rich, light soil, and cuttings root easily under a hand-glass.
Zoph, K., his work on gardening, page 1126. A. D. 1798.
Zygophyllum, bean-caper, decan. monog. and rutaceae, G. tr. and a H. peren. C. B. S. which thrive in loam and peat, and cuttings root readily under a hand-glass.

THE END.
LONDON:
Printed by A. & R. Spottiswoode,
New-Street-Square.
Neutralizing agent: Magnesium Oxide
